The next question I have to draw your attention to, and which is referred to in the report, is the extension of our cables to the West Coast of Africa. I believe you have all read and watched with considerable attention the great interest which has been taken by Continental Powers in what was once called "the Dark Continent." Portugal has been very ambitious, and very sanguine that great returns were to come out of the West Coast of Africa. Germany has been looking at that part of the world, and has made selections there, and they are about to establish settlements. France has not been behind, either. But, after all, I believe England holds by far the most important and valuable parts on the West Coast of Africa. The Government, looking at the development of our settlements on that coast, invited tenders for a telegraphic system to connect this country with the West Coast of Africa. We have always considered it important that we should follow the English flag. Wherever the English flag floats trade is likely to be developed, and as we have been the pioneers in opening up telegraphy all over the world, we thought it would be wrong not to include in our programme the West Coast of Africa—for this reason, that we have from London our line to Lisbon. At Lisbon we join on to the Brazilian Company, which is also an English Company, and managed very much in harmony with the Eastern Company. At St. Vincent we make our departure for the West Coast of Africa. We tendered in connection with the Brazilian Company for this line which our Government desire to lay down. We obtained a concession giving £19,000 per annum. The agreement, which our Solicitor will read to you, enables us largely to control the important British traffic of the West Coast of Africa to a very great extent and without any real cost to this Company. Whatever comes from it will be a feeder to our line, and all that we are likely to invest is to take £75,000 in shares in the new Company, which we shall keep in our safe in very much the same way that we have managed our South African Company, which has been very successful, and we shall thereby obtain control over this new Company which is about to be established. We shall pay for these shares by Eastern Company's debenture stock at 4 per cent. Probably there is no greater evidence of the position and credit of the Eastern Company than the fact that it is able to issue debentures at 4 per cent. I think that is remarkable in the history of submarine cable companies. I am going to ask you to-day to pass a resolution, which will be read by our Solicitor, approving of our expending this £75,000 so as to get us very considerable control over the West Coast system. This West Coast system may eventually be extended to the Cape; but to extend it to the Cape at the present moment would be throwing away money. The British Government has realised that, and the Cape Government has also realised that. But the fact is, that if ever that is required to be extended to the Cape we shall have laid our system to such a length that a couple of months would probably enable us to extend to the Cape if so desired. I think I have laid before you to-day, as far as lies in my power, a very complete statement of your affairs in the past six months, and our reasons for going into this West African venture. I hope it will meet with your approval. With these remarks I will move:—"That the report and accounts of the Directors to the 30th September, 1885, submitted to this meeting, be, and they are hereby, received and adopted." Lord Tweeddale will second this probably, but before I ask your approval of it I shall request the Solicitor to read such points in the agreement as he considers it necessary should be in your possession.

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second the motion.

The SOLICITOR read the main features of the agreement.

The CHAIRMAN: You have heard the agreement, and that is included in our present resolution, and I hope you will approve of it. I will read the resolution again. [Read resolution.] If any gentleman wishes to ask any question before I put the resolution, I shall be only too happy. Then, those in favour of the motion will please hold up their hands. To the contrary. Carried unanimously. The next resolution I have to propose is:—"That Lord Sackville A. Cecil be and he is hereby re-elected a director of the Company."

Sir JAMES ANDERSON: I have much pleasure in seconding that.

The CHAIRMAN put the motion in the usual manner and it was carried.

Lord CECIL: I thank you, gentlemen.

The CHAIRMAN: The next motion is—"That Lord Alfred Paget, who now retires, be and he is hereby re-elected a director of the Company." Lord Alfred Paget has been here this morning, but, as you know, he holds an important position in the Queen's household, and he is obliged to be in attendance to-day on Her Majesty at the opening of Parliament. We are, therefore, deprived of the pleasure of his company on this occasion.

Mr. GEORGE GARDEN NICOL: I have much pleasure in seconding that resolution.

The CHAIRMAN put it in the usual manner and it was carried. Continuing he said: Mr. Price will move, and Mr. Glover will second, the resolution as to the auditors who retire.

Mr. PRICE: I beg to move—"That Mr. Henry Dever, and the firm of Messrs. Quilter, Ball, Crosbie, Glegg, and Wilton, be and they are hereby re-elected auditors of the Company for the currrent year, with a remuneration of £100 each."

Mr. GLOVER: I second that.

The motion was put to the meeting and carried unanimously.

The CHAIRMAN: Gentlemen, the next resolution is—"That the agreement submitted to this meeting dated the 19th January, 1886, and made between the Lords Commissioners of Her Majesty's Treasury of the one part and the Eastern Telegraph Company (Limited) and the Brazilian Submarine Telegraph Company (Limited) of the other part, with reference to the establishment of submarine telegraphic communication between St. Vincent (Cape de Verde) and the British possessions on the West Coast of Africa, be and is hereby approved and confirmed. That the arrangements proposed by the Board for transferring the said agreement to the African Direct Telegraph Company (Limited), and the subscription by this Company of a sum not exceeding £75,000 to the share capital of that company, and the raising of the amount required for such subscription by the issue of £4 per cent. Debenture Stock of this Company be also approved and adopted; and that the Board be authorised to do all such things as they may deem necessary or expedient in this Company's behalf to give effect to the agreement and arrangements aforesaid."

Lord TWEEDDALE (the Vice-Chairman): I beg to second that.

The CHAIRMAN: Now, if there is anyone who wishes to make any remark on the agreement I shall be very glad to listen to him. If not, I will put the motion. Those in favour of it will signify the same in the usual manner. To the contrary. Carried unanimously. Gentlemen, that concludes the business of the day.

Mr. NICHOLSON: I think, before we separate, that we may accord on this occasion a very hearty vote of thanks to our Directors for the very able way in which they have conducted the affairs of the Company during the past half year. I will not detain you longer, but I am sure I carry with me the feeling of our shareholders when I say that at the recent Conference in Germany we felt how ably our interests would be looked after by the Chairman and Sir James Anderson. This vote of thanks which I propose may be tinged with some regret, as I hear, Mr. Pender, that you have come from a sick room to attend here on such a day from a sense of the responsible position which you occupy. I would say that our Managing Director, Sir James Anderson, is so able in the admirable arrangements he makes, and in encouraging traffic, that we as merchants use the cable two or three times a week. He certainly merits our thanks for the ability and readiness with which he on all occasions makes telegraphing easy, and therefore popular. I am sure that my resolution will be readily seconded.

The resolution having been seconded, was carried unanimously.

The CHAIRMAN: I am very much obliged to you, and I thank you on behalf of my colleagues and myself. It is quite true that I have been confined to the house for the last month with a very bad cold, and this is the first public meeting I have been able to address since. I have come before you from a high sense of duty. I feel that the responsibilities which rest upon your Directors and myself in the conduct of this business are very onerous; but I feel also that the more information we can give to our shareholders the more easy is the task of conducting this large and important concern. It is a system that will bring day by day greater influence on the political and commercial system of the world. I therefore hold that this is no ordinary company. It requires no ordinary amount of attention, and it does require a very great amount of intelligence, and sometimes of courage, to carry it on as successfully as we have been fortunate in doing. Your allusion to our visit to Berlin is a just and proper one to make. Your companies were represented there with a very great deal of firmness—so much so, that we were even blamed; and we had not, as I have said, that amount of sympathy in certain quarters that we expected. But we did our duty to you and to the telegraphing public, and we shall continue to perform our duties in that high sense as long as we have the honour of being your Directors. I beg to thank you, gentlemen.

The proceedings then terminated.

Direct United States Cable Company (Limited).

The seventeenth ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on the 22nd January, 1886, under the presidency of John Pender, Esq.

The SECRETARY and TRAFFIC MANAGER (Mr. J. W. Fuller) read the notice convening the meeting, and the report of the Directors and balance-sheet were taken as read.

The CHAIRMAN: Gentlemen, before making the general remarks which I usually do on these occasions, I will refer more particularly, in the first instance, to the report which you have in your hands, and which, I believe, is a very full and explicit statement of the Company's affairs. The revenue for the half year to 31st December, after deducting outpayments, amounted to £38,115, and the working and other expenses, including income tax (but exclusive of cost of repairs), absorb £16,632, leaving a balance of £21,483 as the net profit of the half year, making, with £10,734 brought from the previous half year, a total of £32,217, which has been appropriated as follows: Interim dividend of 3s. per share to 30th September, £9,106. 10s.; interim dividend of 3s. per share to 31st December, £9,106. 10s.; set aside to reserve fund, £8,037; balance carried forward, £5,967—total, £32,217. The revenue shows a reduction of £30,709 as compared with the corresponding period of 1884, owing to the reduction of tariff and competition. The working expenditure compares favourably with that in 1884. The expenses in London show a reduction of £227, while those at the stations, notwithstanding the establishment of three new joint offices at Glasgow, Bristol, and Havre, are only £129 in excess. Taking the expenditure on the whole, and including the increased income-tax item, a reduction of £226 is shown in favour of the half-year under review. The amount of £353. 15s. 5d. for expenses of ss. "Pouyer-Quertier" is a final payment, the agreement for use of this steamer

Digitized by Google

having expired on the 8th November last, and has not been renewed. The reserve fund, with its interest, and with amount set aside from revenue, and after being debited with £3,362. 12s. for cost of repairs to cables, now amounts to £320,000. The present market value of the Company's investments is higher than the amount of their cost to the Company. Gentlemen, these are some of the details of last half-year's working, but there is one remarkable figure which I have given you, and upon which no doubt you will ask me to make some remarks. That item is the revenue, which shows a reduction of £30,709, as compared with the corresponding period of last year. That reduction arises simply from this, that instead of there being five cables in the Atlantic, which would be ample to do the work at the present moment, we have got ten. The Atlantic revenue has never at any time exceeded a million, and it has gone down instead of advancing. Every additional cable that has been laid in the Atlantic has taken away some of the traffic from the existing cables. The position that we occupy at the present time is, strictly, that we have more cables in the Atlantic than are required to do the work, and, consequently, until we get an increase of traffic or an enhanced tariff, I do not see that there is much prospect of our getting increased dividends. But in saying this I believe that common sense must eventually prevail, and that those who have lately put so much money into the Atlantic will begin to find out that they are not getting such a return for their money as they are entitled to, and that they will shortly take steps to bring about a condition of things that will be more satisfactory to them. I do not wish to discourage in the slightest degree gentlemen who may belong to other companies, but this Company occupies perhaps the best position of any submarine telegraph company in the Atlantic business. You have got, as you know, a reserve fund of £320,000 ; your affairs are managed on the most economical principle, and we have until the past year, during the nine years that we have conducted this business, paid you 5 per cent. Why, gentlemen, the reserve amounts to £5. 7s. per share, and if you take that into consideration you will see that the present value of your shares in the market does not represent really half the value of your property. Now, that is a very grand position for us to occupy ; and although the prospect at the moment is not a bright one, still we are in a good position to battle, if it is necessary to do so. Therefore, gentlemen, when I tell you that I feel disappointed with our dividend on this occasion, I am at the same time bound to say, looking at what has occurred in the way of active competition during the past twelve months, that our report is one with which we ought all to be thoroughly well satisfied. During the last eighteen months I have told you pretty well all that would happen. I am not going to refer to the different companies that have brought about this state of things in the Atlantic. I believe one extreme begets another, and that things will right themselves. But this I may say, that taking the value of all the cables in the Atlantic just now, they do not derive such a return as would justify anyone in laying down another, and consequently I believe there will be a stop put to additional competition ; and I hope, before I meet you six months hence, that such an arrangement may be arrived at as to make the tariff remunerative, and bring back a better state of things than exists at present. I dislike, above all things, what I would call throwing away money. The reduction of 4d which was made when the Mackay-Bennett cable came into the market benefited no one. It did not benefit the sender, and it has not increased the traffic. It has been an advantage to no one ; it was merely throwing £200,000 into the sea. I am loth to throw any more money into the sea. I should like to bring about an understanding without what I call "a fight." If we can do so without wasting money, it is so much more desirable and business-like, and more in accord with common sense, and I honestly believe that the men who are opposing us in the Atlantic must see, when they look at their balance-sheet at the end of the year that their investment is not yielding that return to which they are entitled. I am not going to give you their balance-sheet ; I know exactly what it will be, and I know perfectly well that they cannot be satisfied. The Western Union are in the same way. They stepped in and laid two cables, when there was no more necessity for them than there is for putting a fifth wheel upon a carriage. They are beginning to realise that they made a mistake. I hope the result of that will be that we shall come together and arrive at such a conclusion as will cause us not to throw away more money, but to bring more of it into the pockets of the shareholders. With these remarks, I beg to move:—"That the report of the Directors, dated the 13th "January, 1886, together with the statement of accounts for the half-year "ended 31st December, 1885, annexed thereto, be and the same are "hereby received and adopted."

Mr. WM. FORD: I beg to second that.

Mr. JACKSON said he had nothing to say upon the report which was not congratulatory ; but he wished to ask one question. In looking over the statement of investments on account of the reserve fund, he found that the average rate of interest earned by those investments was something like 3½ per cent. And noticing the character of the investments, he observed that there were some that were very much inferior in the estimation of the market to others that would realise a higher rate of interest. He particularly alluded to one of the most substantial securities in the City of London, which he did not see among their assets, namely, the Gas Light and Coke Company's Preference Stock, which would pay 4½ per cent. He wished now to say a few words in reference to the report. Having been long connected with this Company, he wished to signify his very great satisfaction at its present condition, and to endorse, as far as his knowledge would enable him, the remarks the Chairman had made in reference to its position among telegraph companies. No one could prevent the results of competition, as the Chairman had properly said, but a craze was a thing that must run its course, like any other disease, and would cure itself in the long run. Experience would make even fools wise, and he thought there had been a deal of folly in connection with the Atlantic cables. Therefore, he thought they might look forward, not, it was true, to anything very extraordinary in the way of returns, but to the securing of a solid and safe position. He wished to make an observation on a subject which the Chairman, in his modesty, had not adverted to. They must all recognise the great service that Mr. Pender, and the esteemed managing director of the Anglo-American Company, and Mr. Fuller, had rendered to Atlantic telegraphy in fighting their battles at the Conference at Berlin. It was a debt of gratitude that every member of the Company owed to those gentlemen. He took the opportunity, as far as he was personally concerned, of expressing his thanks to them for the labour, self-denial, and discomfort that they had undergone on behalf of all those interested in Atlantic telegraphy by attending the Conference.

Mr. W. H. CUFF wished to know whether the gross traffic for 1885 was an increase or a decrease as compared with that of 1884.

The CHAIRMAN: I am much obliged to Mr. Jackson for the kind and friendly way in which he has spoken. In the first place, I say to Mr. Jackson and to any gentleman here, that if they can make any suggestion to us in regard to any sound investment which will give us a trifle more than that which we are getting, we should only be too glad to listen to it. Probably there is no question that is more honestly or earnestly discussed at the Board than that of investing the reserve fund. We have no prejudice, but we feel, as Directors, that we ought to take no personal responsibility. We ought not to be speculative in any degree, but we ought to secure the best we can for an undeniable security. We have, as Mr. Ford reminds me, talked of such an investment, but, as you know, scares do come sometimes, and there was a very considerable gas scare two or three years ago when the electric light came to the front. I believe in electricity, gentlemen, you know. I believe the electric light must eventually become the light of the future, and without going into any detail on the subject, I may say that I never like to buy a thing when it goes up to something like two or three times the price it cost. I am saying nothing against any investment, but I like to get as near the cost price of an article as I can. What is the result of our investments? We have invested £304,921, and the value of that to-day is £5,000 more than it cost us ; so that we are that amount on the right side at a time when securities are generally rather depressed than otherwise. As I have often said at these telegraph meetings, there is no greater barometer of trade than the telegraph. It is the beginning and the end now of almost every mercantile operation, and, as Chairman of the Eastern and Eastern Extension Telegraph Companies, I can testify to this, that there is a dawn of greater prosperity in the Eastern parts of the world. There is a dawn of greater prosperity in America, and when the cycle of good times comes round—for we have passed through a cycle of bad times —you may depend upon it we shall be in a much better position. There is nothing that will benefit in a greater proportion, by the return of prosperous times, than the telegraph systems with which we are connected. So much, then, for our investments. The Berlin Conference, to which Mr. Jackson has referred, and to which probably I ought to have adverted, was a very important gathering. All the Powers of Europe, and nearly all the important Colonies, were represented at the Conference. The interest of submarine telegraphy, gentlemen, is larger than the whole of the land telegraph system of Europe. But at that Conference we had no vote ; we were allowed to speak and to bring all our facts to bear on the question under discussion, or to do what, I believe, in America they call "button hole" any of the different representatives, but we had no vote. But I must say this, that there was a desire, and a strong one on the part of the Minister of Telegraphs and Posts at Berlin, Dr. Von Stephan—a very intelligent and a very powerful man—to do what he had done, and done successfully, in connection with the postal system. He endeavoured to introduce the same system into telegraphy, but he found it would not answer. If he had carried out his point it would have made a very important difference to telegraph companies. But whether it was through our strong position or the representations that we were able to make, we held our own there, and I believe we left Berlin with the submarine cables in a better position probably than they occupied at any time before. Mr. Jackson has good-humouredly referred to my losing my parliamentary seat, but I can assure you I have lost nothing. Whenever I can serve my country with advantage I am only too glad to do so, but things have been going rather faster than I have been disposed to follow, and I am very glad that I am more at your service than I was before, as I could not have held in the House of Commons some of the extreme views that have lately been put forward. I am perfectly satisfied with things as they are. The volume of telegraphic business to America is less this year than it was the previous year, but I think that is very easily accounted for. You all know that America has been passing through a very severe commercial crisis. Some of the greatest houses have been shaken to their very foundations, and the result of this clearance, I believe, will be renewed action, renewed enterprise, and that must tell on the telegraphic system. Therefore, I look forward to increased traffic in the Atlantic, and, no doubt, we shall have our share of it.

The motion was then put to the meeting, and carried unanimously.

Mr. JACKSON then proposed a hearty vote of thanks to the Chairman.

Mr. STOCKDALE seconded the motion, Mr. GRIFFITHS remarking that Mr. Pender's ability as an administrator of telegraphic enterprise was only equalled by the urbanity of his bearing to all who come in contact with him.

The CHAIRMAN: I beg to thank you on behalf of my colleagues and myself. I can only say that we desire to be frank and explicit with our shareholders. We want you to know all that we know as far as we may speak plainly, because we feel that the more we take you into our confidence, the stronger we are to fight our battles whenever they occur.

The proceedings then terminated.

Anglo-American Telegraph Company.

At a meeting of the Board of Directors of the Anglo-American Telegraph Company (Limited) held on the 22nd inst., it was resolved (after placing £25,000 to the credit of the renewal fund for the quarter ending 31st December, 1885) to recommend to the proprietors at the next half-yearly general meeting of the Company to be held on the 5th February next the declaration of the following dividends:—1. A balance dividend of 10s. per cent. upon the Ordinary Consolidated Stock for the year ending 31st December, 1885. 2. A balance dividend of 20s. per cent. upon the Preferred S ock for the year ending 31st December, 1885. Both payable on the 6th February next, less income-tax. After paying the foregoing dividends there will be a balance of about £4,000 to be carried forward to the next account. The above dividends, together with those already paid, will amount to £1. 5s. per cent. on the Ordinary Consolidated Stock, and £2. 10s. per cent. on the Preferred Stock for the year 1885. The company's register of transfers will be closed up to the 5th February next.

Cuba Submarine Telegraph Company (Limited).

Report and accounts of the Directors for the half-year ended 31st December last, to be presented at the twenty-ninth ordinary general meeting of shareholders to be held at the Company's offices, 61, Old Broad-street, E.C., on February 3rd next, at 1 o'clock.

From the balance sheet and accounts it will be seen that the gross receipts, including the balance brought from last account, amount to £14,966. 12s. 5d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the amount expended on cable repairs) to £6,325. 4s. 6d., leaving a sum of £8,641. 7s. 11d. to the credit of revenue account. The dividend on the preference shares will absorb £3,000, and leave £5,641. 7s. 11d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 7 per cent. per annum, free of income tax, the balance, £41. 7s. 11d., being carried forward to the current half-year's account. The sum of £1,920. 15s. 3d. has been charged to the reserve fund, being the balance of the payment made to the contractors as per contract on the shipment and laying of the Cienfuegos-Santiago cable in 1881. The total payments in respect of this cable now amount to £21,252. 15s. 3d., all of which has been provided for out of revenue, leaving only £3,750 per annum payable for the remainder of the period, viz., to 17th February, 1893, subject to the continuous working of the cable. The fund in the hands of the Company on account of the contractors towards meeting any repairs now amounts to £4,902. 10s. 4d. The Directors have much pleasure in reporting that all the cables are in good working order. The Cienfuegos-Batabano one has, however, undergone some repairs, several faults in shallow water having been cut out by the company's engineer, Mr. Keith. These repairs, which were carried out without interruption to the working, have greatly improved the electrical condition of the cable. The British Government having invited tenders for the laying and maintaining of a cable between Halifax (Nova Scotia), Bermuda, and Jamaica, with an Imperial subsidy, the Board has fully represented to the Government that the scheme, if carried out, would prejudicially affect the interests of this Company.

The Lancashire Maxim-Weston Electric Company (Limited)—In Liquidation.

A general meeting of this Company was held on the 21st inst. at the Cannon-street Hotel, Mr. Thomas Whitworth in the chair.

The report of the liquidators having been taken as read,

The CHAIRMAN said that he had not very much to add to the report. The liquidators had touched on all points which they thought were of interest, and he reserved any remarks in case any inquiry might be made regarding anything that was not perfectly clear in the accounts. Either Mr. Brown or himself would be happy to give any information. He could only say that the undertaking, which they entered into with a light heart last March twelve months, had been a very much more arduous undertaking than they anticipated or expected. They had been met at every turn with difficulties, which, he thought, only their solicitor, Mr. Brown, and himself could appreciate. Mr. Brown had had the whole of the accounts of the Company in his hands, and was thoroughly conversant with each of the items, and if any questions were asked he would answer them.

Mr. BROWN said that he could only reiterate what Mr. Whitworth had said. They had had a very difficult task, and he congratulated them that they had arrived at the compromise they had effected. He believed that all would agree that that was a very satisfactory matter. That gave them half the capital that the y had to divide. The sale of the plant had been the principal thing. The amount paid to the parent company was about £3,400, and they realised £1,651 from the sale of the plant in the most difficult time that was ever known. Had it not been for the claim of the Maxim-Weston Company for £10,000 they would have declared a dividend of something like 14s. in the pound, but they were obliged to bow to the decision of the Court, and they had acted upon it, sanctioned and confirmed. As far as he was concerned in the matter, he should not like to undertake such another liquidation, and he was pleased that it had come to an end.

After some remarks from Mr. HAINES (the solicitor) and a shareholder as to the wisdom of the course pursued by the liquidators,

Mr. GRAY said he quite agreed that the liquidators had undertaken a most arduous duty. He moved, "That the accounts submitted to this meeting, showing the manner in which the winding-up has been conducted, and the property of the Company has been disposed of, be received and adopted."

The motion was seconded by Mr. SWABEY, and carried unanimously.

A resolution was then passed, authorising the liquidators to hand over the books of the Company to the Maxim-Weston Company.

Mr. GRAY then moved that the liquidators be requested to accept the sum of £29. 9s. 9d. appearing in the accounts, or any other balance that may be in their hands, or under their control, not exceeding in the whole £30, as an acknowledgment for the extraordinary and unexpected trouble which they have had in the liquidation, they undertaking to discharge any liability to the extent, but not beyond, the amount of the sum they so receive.

Mr. WALKER seconded the motion, which was carried, and the proceedings then terminated.

LEGAL.

The Pall Mall Electric Association.

In the Chancery Division of the High Court of Justice, on Monday, before Mr. Justice Chitty, Mr. INCE, Q C., moved *ex parte* for leave to serve copy of a petition for its winding up upon the Pall Mall Electric Association, which had its offices at 21, Holborn Viaduct, with a branch in Regent-street. The special object was that the notice should be answerable on Saturday. The Company was formed in November, 1881, and part of its business was the manufacture and sale of electric brushes, belts, and medical appliances. The capital was £16,000, in £5 shares. The petitioner, Mr. Baker, agreed with the company to hold for their benefit his "belt of life," and other trade marks, for which the Company were to pay him 5 per cent. on all sales. Balance sheets were to be drawn out regularly, but this had not been done. The Company now owed the petitioner £600. Mr. Baker had recently been in America, and on his return he learned that the company had passed a resolution to wind up. Unless, therefore, his petition could be heard on Saturday, there would be no company to wind up.

The JUDGE directed that notice of the petition should be served that day at the office of the company, and that the required advertisements should be published on the earliest possible date in the *Gazette* and two London papers.

NOTICE OF TRANSFER.—The supply department, at 11, Queen Victoria-street, London, E.C., of Messrs. Woodhouse and Rawson's electrical business, for the sale to merchants, shippers, and the trade, was transferred on the 26th inst. to a limited company, with a registered capital of £100,000.

NOTES.

THE CANADIAN TELEGRAPHS.—Wooden telegraph poles in Canada are being replaced by iron poles.

A NEW BATTERY.—We are promised from France a new sulphate of copper cell. It is to be something wonderful.

SOUTH AMERICA.—The lines between Mexico and Vera-Cruz, and between Queretaro and San Luis Potosi are now duplexed.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 29th ult. amounted to £3,121.

RESIN.—Resin retains its insulating properties unimpaired until after the melting point is reached. It conducts when in a liquid state. This applies to all the resins.

GENEROUS.—We are informed that Mr. J. W. Mackay has presented the whole of the *employés* of the Commercial Cable Company with a bonus of half a month's pay.

THE POSTMASTER-GENERALSHIP.—At the time of our going to press no definite appointment had been made to the Postmaster-Generalship under the new Government.

THE ERUPTION OF COLIMA.—A Reuter's telegram, dated New York, January 31, says a telegram from Mexico states that the Colima volcano continues in active eruption.

A SNOW STORM.—A snow storm, with a gale, which is described as of cyclonic fury, passed over the Peterborough district on Sunday afternoon, doing much damage to telegraph wires.

BALATA AS AN INSULATOR.—Balata, which is obtained from the bark of the bullet tree (*Mimusops balata*), of Guiana, is said to possess electrical insulating properties quite equal to those of gutta percha.

A LONG TRANCE.—It is stated from Nebraska that a young woman resident there was awakened by a shock from a galvanic battery, after having remained in a cataleptic trance for seventy days.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of January amounted to £1,686, against £1,756 in the corresponding period of last year.

UTILISING NIAGARA.—The Niagara Falls and Whirpool Railway Company has been incorporated, with $100,000 capital. As yet it has not been decided whether steam, water, or electricity will be used.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELGRAPH COMPANY.—The traffic receipts of this company for the month of January, amounted to £39,699, and to £44,144 in the corresponding period of 1885.

THE BENEVOLENT ASPECT OF EARTHQUAKES.—Mr. Proctor is of opinion that, paradoxical as it may sound, the earthquake is a regenerative and restorative agent. To quote an Americanism, "We don't want any in ours, thank you !"

LIGHTING VEHICLES.—It is said that the King of Bavaria has some fine sledges, in which he frequently travels by night. He very much wished to have them electrically lighted, but, unfortunately, no room was available for the accumulators.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 29th ult. were £2,438, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

EARTHQUAKE IN SPAIN.—A Reuter's telegram, dated Madrid, January 30th, says :—"Yesterday afternoon a strong shock of earthquake was felt at Velez Malaga. No details have yet been received, but the town is reported to have suffered little damage."

ANOTHER UNDERGROUND SYSTEM.—A new underground wire system, originated in New York, contemplates the construction of two arched subways, so that wires carrying strong currents shall not inter-act upon those designed for the telegraph and telephone.

THE ELECTRIC LIGHT IN FRANCE.—La Gare de l'Est, at Paris, is now electrically lighted by Cance arc lamps. The substitution of the new luminant for gas is already much appreciated, and we hope to hear shortly of some extensions being made in this direction.

NOTICE OF MEETING.—The usual half-yearly ordinary general meeting of the Anglo-American Telegraph Company will be held this day (Friday) at the Cannon-street Hotel, at two o'clock precisely. A full report of the meeting will appear in our issue of the 12th inst.

THE TELEPHONE COMPANY OF AUSTRIA.—The accounts of this company, from the date of incorporation to June 30 last, show a credit balance to revenue of £432, which the directors propose to carry forward. The accounts are in future to be made up annually to March 31.

MAXIM-WESTON.—It is announced that the directors of the Maxim-Weston Electric Company have decided to pass a sum of £3,600 to a general reserve account, and to recommend a dividend of 7½ per cent. for the past year, carrying forward a balance of about £600 to next year.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 31st ult. are £2,799, as compared with £2,766 in the corresponding period of 1885. The October receipts estimated at £3,894 realised £3,940.

FRANCE AND TONQUIN.—Since Friday night last France has been in communication with Tonquin without military supervision, an independent telegraph office having been established at Lang-Son, through which not only official but commercial messages pass in the ordinary way.

ELECTRIC ROAD ROLLERS.—Mr. E. Gellerat's electric road roller is again exciting attention. As will be remembered it is driven by two dynamos and steered by another dynamo. About 100 accumulators are used, and the gross weight of the machine is 18 tons. About 13 horse-power is developed altogether.

ITALY AND THE RED SEA.—It is reported from Rome that the Italian Minister of Public Works is about to lay a proposal before the Government for the establishment of a submarine telegraph cable between Massowah and Assab Bay in connection with the system of the Eastern Telegraph Company.

THE ELECTRIC LIGHT AND SCIENTIFIC RESEARCH.—A new apparatus for the application of the electric light to microphotography has been designed by M. Yvon. An incandescent lamp supplied with current by a six-cell Trouvé battery is used. The advantage is that the light is uniform and steady.

THE BRITISH ELECTRIC LIGHT COMPANY.—In the Chancery Division of the High Court of Justice, on Friday last, Mr. Justice Chitty heard an application by debenture-holders in this company for the appointment of a receiver. The learned judge granted the application, and appointed the secretary of the company as receiver.

PROPOSED LIGHTING OF A BOROUGH.—At their last monthly meeting the Hanley Town Council passed a resolution,

Digitized by Google

on the recommendation of the General Purposes Committee, appointing a sub-committee to consider the desirableness and the cost of lighting the public buildings, and eventually the public streets of the borough, by electricity.

RESISTANCE AT LOW TEMPERATURES.—From some experiments carried out by M. Wroblewski, it would appear that the variation in the resistance of copper is proportionate up to a very low temperature. In every case the coefficient only varied ·0004 between + 21°C. and − 193°C., but at − 200°C. it became ·00197 higher in one case, and ·002819 in another.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 3,485, estimated to produce £2,850, against 3,555 messages, producing £3,013, in the corresponding month of last year. The traffic receipts for the month of October, estimated at £2,100, realised £2,156.

OVERHEAD WIRES.—Sir Henry Tyler has given notice of his intention to ask the Home Department for a return of the failures of telegraph and telephone wires, used overhead in the metropolis, during the recent snowstorm, and of the accidents thereby caused. The question thus raised is an important one, both as affecting the public and the telephone companies.

ST. JAMES'S VESTRY AND THE ELECTRIC LIGHT.—At the last meeting of the St. James's (Westminster) Vestry, the Lighting Committee recommended that the Board of Trade be requested to oppose the Bill of the West London Electric Lighting Company, and that the vestry do oppose the draft provisional order as a whole. The recommendation was adopted.

ROYAL INSTITUTION.—At the general monthly meeting of the members, held on Wednesday, Mr. Warren de la Rue, D.C.L., F.R.S., vice-president, in the chair, Messrs. Wm. Anderson, C.E., H. A. Blyth, J. Blyth, J. Crowdy, Brownlow D. Knox, and W. F. R. Weldon, M.A., and Mrs. Shepherd were elected members, and 16 candidates for membership were proposed for election.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, on Thursday, 11th February, 1886, when a discussion will take place upon the paper, "Self-Induction of an Electric Current in Relation to the Nature and Form of its Conductor," by Prof. D. E. Hughes, F.R.S, President.

CITY GUILDS TECHNICAL COLLEGE: OLD STUDENTS' ASSOCIATION.—The first ordinary general meeting of this recently-formed association was held at the Finsbury Technical College, on the 2nd inst. A paper was read by Mr. E. Smart upon the Swanikoff arc lamp, for which he claimed simplicity of construction and steadiness of action. A discussion followed in which Mr. Walmsley and others took part.

THE TELEPHONE IN EDINBURGH.—At the last meeting of the Edinburgh Town Council it was agreed to accept the estimates of the National Telephone Company for wire from the Exchange to the City Hospital at £15 per annum, and for wire to the City Chambers at £10 per annum, and the estimate of Alexander Maclean and Co. for wire from the City Hospital to the office of the medical officer of health at £5 per annum.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—The accounts of this company for the past year show an available sum of £158,326, including £40,070 brought forward and £52,394 premium on new shares issued during the year. A dividend of 15 per cent. is proposed, of which 5 per cent. was paid in July. The sum of £55,000 is to be added to reserve, leaving £40,947 to be carried forward.

THE ELECTRIC LIGHTING ACT.—At a general meeting of the Electric Lighting Act Committee, recently held at the offices of the Anglo-American Brush Electric Light Corporation, Belvedere-road, Lord Thurlow in the chair, a resolution was adopted, on the motion of Viscount Anson, approving the action of the executive, and expressing satisfaction at the announcement that Lord Rayleigh had, at the request of the executive, agreed to introduce the Bill drafted by the committee into the House of Lords.

THE NATIONAL TELEPHONE COMPANY.—At a meeting of the directors of this company, held on Wednesday last, it was resolved to declare an interim dividend for the six months ending 31st December last at the rate of 6 per cent. per annum on the First and Second Preference shares, and at the rate of 3 per cent. (as against 2 per cent. for the corresponding period last year) on the Ordinary shares, and that the balance of £2,685. 5s. 2d. should be carried forward. The unaccrued revenue carried forward to the credit of next account amounts to £34,058. 18s. 10d., as against £29,995. 16s. 5d. last year.

TO INDICATE FIRE DAMP.—An apparatus has been invented by a Mr. Carleton, of New York, for the purpose of indicating fire damp in coal mines. It consists briefly of two mercury bulbs, the ends of which are inserted into helices of fine wire. The two bulbs are equal in bulk, and the two helices of the same resistance. One bulb is placed in a pure atmosphere of any required temperature, and the other in a current of air flowing from or in the mine. The difference in resistance between the two bulbs is then, from time to time, measured electrically, and the amount of fire damp ascertained.

MANILA ROPE.—As Manila rope enters very largely into deep-sea grappling, the following may interest some of our readers:—To detect the presence of adulterations, such as sisal fibre, in presumably pure Manila rope, untwist a small piece, and prepare the yarn by carefully separating the fibres, roll into a ball in the palm of the hand, and then burn out on an iron shovel. Pure Manila hemp will give a dull, grayish black ash; sisal hemp will give a whitish grey; and sisal and Manila mixture a grizzly white and black ash. The different fibres are distinctly visible.

BATTERY SOLUTIONS.—M. Damian has found that a zinc, copper, sulphate of magnesia cell gives excellent results. The E.M.F. varied only 0·02 volt during ten months, its maximum being 1·06 volt. The solution continues clear, and the surface of the metals clean. The E.M.F. is not affected by the degree of concentration of solution, and temperatures between 6° and 35° C produce no appreciable effect. For a cell of amalgamated zinc, platinum, and dilute sulphuric he found the best results when the solution contained 30 to 100 of acid, and was at a density of 1·223. The E.M.F. was then 1·345 volts at 15° C.

COMMUNICATION WITH CANADA.—At a recent meeting of the Montreal branch of the Imperial Federation League, the following resolution was passed:—"That this meeting is, therefore, strongly of opinion that a petition should be presented by the Imperial Federation League to the Dominion Government, praying it to take such steps as it may deem best fitted, by money grant and otherwise, to encourage the formation of an organisation by the Canadian Press, independent of party, for the purpose of securing a daily telegraphic interchange of news with the mother country, which shall be free of all influence external to the Empire.

ANNUAL DINNER.—A few nights ago the *employés* at the Arc Electric Light Works, Chelmsford, had their annual dinner at the Corn Exchange. Provision was made for 289 guests. During the course of the evening Mr. R. Britton, in a happy little speech, gave "The firms of Messrs. R. E. Crompton and Co. and Messrs. Crompton and Fawkes." He stated that at the first dinner he attended in connection with the firm 29 men were present, and at the second there were something like 43. He also spoke of the time when only one man was employed in Chelmsford in connection with the electric light industry. Mr. Britton then referred in complimentary terms to the heads of the two firms.

INFLAMMABILITY OF COAL DUST.—According to some recent experiments carried out in the Königs Mine at Neunkirchen, in Germany, the flame from a blast hole filled with coal dust attains to a length of from 26ft. to 164ft., according to the quality of the coal. Ignition was effected by electricity. The use of electricity and the electric light is referred to by the *Eisen Zeitung* in connection with these experiments, recent investigations having proved that electricity separates dust, smoke, gas, &c., from the air, and deposits them upon the walls of a vessel, tunnel, or shaft. By the use of hermetically closed lamps it is possible, moreover, to keep electric light from contact with gases in mines.

BRUSSELS.—M. Léon Somzee is urging upon the Belgian Government the necessity of taking measures to obviate the dangers resulting from the use of overhead telephone and telegraph wires in towns. He also recommends the appointment of a special commission to examine into and determine the tensions which, presumably in electric light leads, may be employed with absolute safety to life. M. Alph. Nothomb demands that this commission shall also study the question of the dangers to life and property resultant upon the usage of gas. This is but fair, for there are certainly two sides to this question. It will be remembered that M. Somzee is practically the representative of the gas interest in Belgium.

SOCIETY OF ENGINEERS.—The first meeting for the present year of the Society of Engineers was held on Monday evening at the Westminster Town Hall. The President for 1886, Mr. Perry Fairfax Nursey, in his inaugural address, speaking of the present advanced state of engineering science and practice, observed that the people were rather prone in the present to exalt themselves at the expense of the ancients, although the latter had manifested in many instances a large amount of scientific skill and knowledge. As an instance of this fact, it was true that the electric telegraph was defined by Galileo in his "Systema Cosmicum" two centuries and a half ago; while the lightning conductor of Franklin was used by the Etruscans.

RIVAL CODE BOOKS.—In the Chancery Division on Wednesday last, the case came on for hearing in which Dr. George Ager, the compiler of "The Standard Telegraph Code," a book sold for £5. 5s. a copy, proceeded against Messrs. Collingridge for printing what was alleged to be a pirated edition of the work for Messrs. Shadbolt, the compilers of what was called "Shadbolt's Telegraph Code," adapted specially for the timber trade. The defence was that the plaintiff's book was not a proper subject for copyright, and that they had never had any intention of using their version of it except for themselves and their correspondents. Mr. Justice Kay held that the book was copyright; but as the defendants were going to appeal he pronounced no decision on the question of damages.

THE ELECTRIC LIGHT FOR WARSHIPS.—Orders have been received at Sheerness directing the "Caroline," 12, unarmoured screw corvette, 1,620 tons, 1,012 horse-power, Captain Sir William Wiseman, to be fitted with the electric search-light before her departure for the Pacific Station to relieve the "Satellite." The Admiralty some time ago ordered the "Alacrity," despatch vessel, to be instantly prepared to temporarily relieve the "Helicon" as tender to the flagship in the Mediterranean, without waiting to receive her armament, steam steering gear, or electric lighting. They subsequently countermanded the order, instructing the dockyard authorities at Portsmouth to prepare her for her guns, and to complete her equipment for a regular commission at sea.

FUNERAL OF A TELEGRAPH MESSENGER INSPECTOR.—On the 28th ultimo, at Highgate Cemetery, the remains of the late Inspector George Rose, of the Central Telegraph Office, General Post Office, were interred in the presence of a large gathering of friends and brother officers of the deceased. A detachment of fifty messengers from the Central Telegraph Office, under Chief Inspectors Howard and Austin, assisted by Inspectors Reid, Brown, Doran, Parsons, and Cromarty, paraded outside the cemetery gates at 3 p.m. to pay a last tribute of respect to the deceased officer, and followed in procession to the grave. A handsome wreath of natural flowers presented by the inspectors, tube attendants, and messengers of the Central Office was placed upon the coffin, together with others, sent by the deceased's friends.

SCIENCE AND POPULAR GOVERNMENT.—Discussing this matter in the present month's *Nineteenth Century*, especially as illustrated by the American democracy, Mr. E. L. Godkin, says: "The kind of fame which came to Edison after he had made some improvements in the electric light and invented the phonograph, was a very good illustration of the respect of American people for the novel and the marvellous. For a good while he was hailed as a man to whom any problem in physics would be simple, and he was consulted on a variety of subjects to which he had given no attention, such as the means of diminishing the noise of the trains on the elevated railroads in the streets of this city [New York]. In fact, for a year or two, he held the position—doubtless to his own amusement—of a 'medicine man,' to whom any mystery was easy."

BALLOONING.—In Captain Renard's experiments, which took place on the 22nd of August, and the 22nd and 23rd of September last year, the motor employed was a Gramme dynamo electric machine making 3,000 revolutions a minute, and developing 9 horse-power. The current actuating the machine was furnished by a battery. On the 22nd of September the speed of the wind was from 3 metres to 3·50 metres per second. The balloon left Chalais, carrying three persons, at 4:25 p.m., the sky being cloudy. It was steered against the wind, and at 5 p.m. arrived over the Ile de Billancourt with a speed of 6 metres per second, the Paris fortifications being reached at 5:12 p.m. The return journey was accomplished in 11 minutes, while the outward journey had occupied 47 minutes. The maximum height attained was 400 metres.

EDINBURGH TELEGRAPH MESSENGERS.—On the 27th ultimo the fifteenth annual entertainment to the Edinburgh telegraph messengers was given in the Waverley Hall. Mr. Andrew Gray, superintendent, who presided, said that since their last meeting there had been a considerable change in regard to matters telegraphic by the introduction of a lower rate for telegrams. This change had increased the difficulties and labours of the boys considerably, owing to people sending messages addressed, for instance, "John Smith, Grassmarket," no number being given. This was probably want of thought sometimes; but some people had no scruple in asking the boy to take a great deal of trouble for the penny that he received

Digitized by Google

so that they might save one themselves. The object of the telegram was to effect speedy communication; and those who were so pennywise sometimes defeated their object.

ANIMAL ELECTRICITY.—Another very remarkable cure is said to have been effected at Whitstable by means of animal electricity. A nephew of Captain Foster, of Victoria-street, was suffering from St. Vitus's dance in its worst form. Previous to Christmas he could neither hold his head nor a limb still, nor even dress himself; but two or three weeks ago the case was brought under the notice of Mr. Barham, a member of the Anthropological Institute of Great Britain and Ireland, a gentleman who has given careful attention to the science of animal electricity, and is an ardent believer in it. Mr. Barham's method of treatment was immediately successful, and the patient, a boy of about fifteen years of age, is now restored to health. He can dress and undress himself, and has not the slightest symptoms of twitching. The operator, it is said, has been equally fortunate in the treatment of paralysis.

NEW FORMS OF THERMOPILES.—In this paper, by H. Kayser, measurements are given of the electromotive force and resistances of various forms of thermopile, the source of heat being a gas flame burning a known number of litres of gas per hour. The electromotive force of a Noë-Rebiceck's thermo-electric pile of 20 elements was found to be constant for an indefinite length of time, provided that the external conditions, namely, gas pressure and temperature of the air, were unaltered; its electromotive force also exceeded that of a Bunsen element. The internal resistance increased to a maximum, with a consumption of gas from 0—60 litres per hour, and from that point to 110 litres per hour it diminished; the maximum resistance of a pile of 25 elements was 0·868 ohm. The relative advantages of a thermopile over a Bunsen element in cases of small external resistance are also discussed.—*Jour. Chem. Soc.*

PIGEONS AS MESSENGERS IN WAR.—Lecturing on this subject, on Friday last, at the United Service Institution, Captain H. T. W. Allatt pointed out that our telegraphic communications with the external world might be severed without an invasion. Our submarine cables might be cut by an enemy who had never come within sight of our island, and it would obviously be difficult to watch and protect them all. In such an emergency pigeons would afford a means of maintaining direct, cheap, and speedy communication with the Continent. A further use of the birds applicable to our insular position would be found in their employment as messengers from an observation ship or fast cruiser told off to watch an enemy's fleet. By having a suitable number on board every movement of the enemy could in moderate weather be reported in the day-time to a military station on shore.—A discussion followed, in which the chairman (Sir Beauchamp Walker), Major-General Hassard, and others took part.

DOMESTIC LIGHTING.—Last week on the occasion of a ball given by Sir A. B. Walker, Bart., at Osmaston Manor, near Ashbourne, the mansion and ball room were lighted by the electric light, some 200 sixteen candle-power incandescent lamps being used for this purpose. Sir Andrew Walker having decided to light the house placed the order for carrying out the work in the hands of the Liverpool Electric Supply Company early in January, and by the 29th ult. a twenty horse-power compound engine of Messrs. Marshall and Sons' make had been fixed in position and was driving a dynamo capable of supplying 400 lamps, to which extent it is intended to increase the lighting. The work of building the engine shed and erecting the plant was carried out under considerable difficulties owing to the short time available. The fittings for the house have all been carefully designed with a view to their adaptability to the different rooms. The whole of the work was superintended by Messrs. Holmes and Vaudrey.

REGULATING THE TEMPERATURE.—Another device for automatically maintaining an even temperature in enclosed places by means of electricity was recently shown at the American Institute Fair. The apparatus consists of a wooden frame, which may be placed either in the upper or lower sash, divided into alternate parts of glass and metal. The metal strips are pivoted at each end and all attached to one metal bar, which is connected at one end of the frame with the armature of an electro-magnet, covered by a wooden box, and the other end is drawn back by a spiral spring. The thermometer has a wire let into the bulb, and also one fused into the glass tube at any desired degree. The electro-magnet, thermometer, and battery are connected by insulated wires. The mercury in the tube, acting as part of the conducting wire, as it rises and falls, connects, and disconnects, with the wire fused in the side of the tube, thus alternately attracting and releasing the armature, and thereby opening and closing the movable slats in the frame.

ANOTHER MINER'S LAMP.—At the recent conference of the Miners' Union, Mr. Burt, M.P., the president, observed that a very desirable thing was the provision of a good useful light. An electric lamp for the miners' personal use was an admirable thing. They had one before them, which was self-contained, and consisted of a battery composed of three cells, each 6in. high by 3in. wide and 1in. deep. Each cell consisted of a charge of chloride of silver and two thin zinc plates, a weak solution of caustic potash being added. The current produced supplied a small glow lamp, of German manufacture, placed in front of the metallic case containing the battery after the fashion of the bull's-eye of a police lantern. The light by this lamp was stated to be of 3 candle-power, and to be capable of burning for nine hours; but this, as far as candle-power g oes, is in excess of the requirement of the miner, so that smaller sizes are made. One of these is circular in form, 3i n. in diameter, 3in. deep, and of 2 candle-power, and will burn for five hours.

THE INDIAN TELEGRAPH SERVICE.—*The Times* Calcutta correspondent writes:—Saturday's official *Gazette* contains the annual administration report of the Indian Telegraph Department, and a highly appreciative Government resolution thereon. The year under review was marked by a great development of the telegraphic service. The number of Government signal offices was increased 50 per cent., and the total number of offices, including those of the railways, is now 2,035. The length of the lines was increased by 2,046 miles to 25,387 miles, and the length of the wires by 6,279 miles to 75,115 miles. The Burmah-Siam line has been successfully completed, and a new cable has been laid to Ceylon. The surplus revenue was Rs.11,67,918, being 3·3 per cent. on the capital expenditure. The revenue was the largest yet earned, the number of complaints diminished, the speed of transmission was improved, the interruptions were decreased in number, and the arrangements for utilising the agency of the Post Office made progress during the year.

COMMUNICATION AT SEA.—Prof. Bell says:—"Most of the passenger steamships are equipped with electrical plant. Suppose one of them should trail a wire of any length, which is connected with the dynamo engine and electrically charged. The wire would have an earth connection by trailing in the water. Suppose a telephone was then attached to the end on board. Then the dynamo or telephone end would be positive, and the other end of the wire in the water would be negative.

Digitized by Google

All of the water about the ship would be positive within a circle whose radius is one-half of the length of the wire. All of the water about the trailing end of the wire will be negative within a circle whose radius is the other half of the wire. If the wire is one mile long, there is then a large area of water about the ship which is affected either positively or negatively by the dynamo engine and the electrically charged wire. It will be impossible for any ship or object to approach within the water so charged in relation to the ship, without the telephone telling the whole story to the listening ear. Now, if a ship coming in this area also has a similar apparatus, the two vessels can communicate with each other by their telephones. If they are enveloped in a fog, they can keep out of each other's way. The ship having the telephone can detect other ships in its track, and keep out of the way in a fog or a storm. The matter is so simple that I hope our ocean steamships will experiment with it. The principle is not new; it is old, with a new use waiting for commerce to utilise it." This looks very nice, but even if the wire so trailed were, say, a mile in length, there would only be a working radius of half a mile. Close quarters; to say nothing of the inconvenience of trailing a mile of line.

Some Considerations Regarding Induction.—In the current issue of our American namesake appears a very interesting article by Mr. David Brooks upon the phenomena of induction in relation to the working of telegraph and telephone lines. After declaring that induction is not a myth, the writer goes on to say that it can only be produced, or at least developed to its greatest extent, by very high insulation, whether upon parallel conductors or in induction coils. The inductive effects are lessened as neighbouring conductors are multiplied, and are more pronounced upon overhead telephone wires in clear cold weather than when rain prevails. The law of inductive effect between wires is laid down by present writers as being inversely in proportion to the distance by which they are separated by insulation. Take, however, 100 telephone wires strung upon a line of poles so that the 100 conductors occupy a sectional space of 100 square feet. If these wires extend one mile, and are used exclusively for telephone purposes, very marked inductive effects are observable. In the telephone cable the wires are 14,400 times nearer to each other, and the inductive effects should be 14,400 times greater, but they are not. It is probably more a matter of acoustics. Cotton, or other textile material, saturated with paraffin, has much less electrostatic capacity than paraffin itself, and cotton-covered wire, when saturated with oil, has a much less electrostatic capacity than when saturated with solid paraffin. The more compact the cotton covering, and the less oil or paraffin absorbed by it, the less the electrostatic capacity. Moderately low insulation is the best condition for automatic telegraphing or telephonic operations, say one megohm per mile. Retardation is the result of too high insulation. In such case the use of artificial leaks is advised.

The Lighting of Askam.—At the last meeting of the Dalton Local Board the Electric Lighting Committee reported as follows:—"In continuation of their report, submitted to the Board in November last, the committee have to state that, having considered the report of the engineers (Messrs. Badger and Sons, of Rotherham), upon the condition of the engine and boiler originally proposed in his specification to be furnished by Mr. Menzies for electric lighting purposes, which the engineers found in many respects defective, and to require considerable repairs, the committee could not accept the same. The above recommendation is made to the Board for adoption, subject to the Local Government Board's approval of the electrical lighting scheme. That the former resolutions of the Board in reference to the application for loan be varied as follows:—That application be now made to the Local Government Board for sanction to borrow the sum of £1,600 for electric lighting purposes, the repayment whereof shall extend over a period of 20 years." Mr. Hammond moved the adoption of the report. He said Prof. Jamieson's report showed that the place was well adapted for the light; it also suggested that they should have an additional dynamo, in case of accident. The Board would get 120 lamps, with double the illuminating power, at the same price that they were paying for 60 lamps. They could with the proposed plant extend the number of lamps to 240 without extra man or labour. The total cost, including engine house, &c., would be £1,542. It had been thought wise to have a report as to the second-hand engine, and it had been unfavourably reported upon, and tenders were obtained for another engine and boiler. They proposed to apply for power to borrow £1,600, although he did not think the whole of this sum would be expended. At the same time the committee thought it advisable to apply for £1,600. The report was adopted.

Electrical Tramways.—Mr. Gooch has summarised the comparative values of cable and electric tramways, in the *Yorkshire Post*, as follows:—"(1) Excessive first cost of construction. (2) That if the cable is broken the whole of the traffic in both directions is suspended until repaired. (3) Should one of the cars be delayed, it practically impedes during the journey the whole of the others, as it cannot recover the time lost by going faster than the rate the cable nominally travels. (4) The cable runs on pulleys at short intervals; consequently you have a very large number of moving parts, which require lubrication and adjustment, and are apt to cause great inconvenience and delays, to say nothing of cost in money and labour. (5) On an extensive system the weight of the cable and consequent friction absorbs a large portion of the power unproductively. (6) Sharp turnings, crossing places, and sidings, &c., can only be worked with great difficulty. (7) There is no possibility of backing a car to avoid collision, or for other necessary purposes. This is a sufficiently formidable summary of objections to the cable system, and, at the same time, does not give all." Turning to electricity, and using only storage batteries for the motive power, as used at Berlin and Antwerp, the cars thus driven: (1) "Have few but reliable mechanical working parts. (2) Are independently driven, any car being able to make up time in case of delay by going faster. (3) There is no noise such as is inseparable with the running of cables over pulleys in the centre of the street. (4) No other permanent way is required beyond the ordinary tram rails. (5) Electric traction by storage will be found more reliable and more economical than traction by the cable system. (6) The electrical system is capable of any expansion by placing an increased number of cars in service, whereas the cable system is necessarily restricted to a certain amount of work in accordance with the original strength of parts and power supplied. (7) The deterioration, if any, of the transmitting power is localised to each cor, and is not general as in the case of the deterioration of a cable on which the haulage of many cars depends. (8) The sidings, turnouts, sharp curves, and other ordinary difficulties of the road are perfectly dealt with by the storage system. The same favourable remarks apply to electrical systems in which the transmission of power to the car from a central station is arranged for."

ELECTRICAL THEORIES.*

BY PROF. J. J. THOMSON, M.A., F.R.S.

In this report I have confined myself exclusively to the consideration of those theories of electrical action which only profess to give mathematical expressions for the forces exerted by a system of currents, and which make no attempt to give any physical explanation of these forces. For it is evident that, before we can test any theory of electrical action, we must know what the actions are which it has to explain, and we cannot do this until we have a satisfactory mathematical theory. I have further limited myself to the consideration of the fundamental assumptions of each theory, and have not attempted to give any account of its mathematical developments, except in so far as they lead to results capable of distinguishing between the various theories.

I have divided the theories into the following classes:—

1. Theories in which the action between elements of current is deduced by geometrical considerations, combined with assumptions which are not explicitly, at any rate, founded on the principle of the "Conservation of Energy." This class includes the theories of Ampère, Grassmann, Stefan, and Korteneg.

2. Theories which explain the action of currents by assuming that the forces between electrified bodies depend upon the velocities and accelerations of the bodies. This class includes the theories of Gauss, Weber, Riemann, and Clausius.

3. Theories which are based upon dynamical considerations, but which neglect the action of the dielectric. This class contains F. E. Neumann's potential theory and Von Helmholtz's extension of it.

4. C. Neumann's theory.

5. Theories which are based upon dynamical considerations, and which take into account the action of the dielectric. This class includes the theories of Maxwell and v. Helmholtz.

We shall now proceed to the detailed consideration of these theories.

The best known theory of this class is that of Ampère; others, however, have been given by Grassmann, Stefan, and Korteweg, which we shall consider in order.

Ampère's Theory.

This theory was first published in 1820. In 1823 appeared his great paper the "Memoire sur la theorie Mathematique des phénomenes Electrodynamiques," "Memoirs de Institut," t. 6, which Maxwell describes as "perfect in form and unassailable in accuracy," and which at once brought the action between electric currents under the power of mathematics. Ampère founded his theory on certain postulates which he attempted to establish by experiment; inasmuch, however, as he always dealt with closed circuits in his experiments and elements of circuit in his postulates, the experimental evidence is not quite satisfactory. Ampère's experiments have been repeated by Von Ettingshausen,† with much more delicate apparatus.

The postulates used by Ampère are as follows; the first four are given in the words of Prof. Tait [Tait's "Quaternions," 2nd Ed., p. 279]:—

I. Equal and opposite currents in the same conductor produce equal and opposite effects on other conductors, whence it follows that an element of one current has no effect on an element of another which lies in the plane bisecting the former at right angles.

II. The effect of a conductor bent or twisted in any manner is equivalent to that of a straight one, provided that the two are traversed by equal currents and the former nearly coincides with the latter.

III. No closed circuit can set in motion an element of a circular conductor about an axis through the centre of the circle and perpendicular to its plane.

IV. In similar systems traversed by equal currents the forces are equal.

V. The action between two elements of current is a *force* along the straight line joining them, and proportional to the product of the lengths of the elements and the currents flowing through them.

It follows from IV. that the force between two elements of current varies inversely as the square of the distance between them. The assumption V. is one that can only be satisfied by the correctness of the results to which it leads. We have no right to assume *a priori* that the action is equivalent to a single force and not to a force and a couple, and we have no more right to assume that the force is along the line joining the elements than we have to assume that the force between two small magnets is along the line joining their centres, and in this case the assumption is untrue. It is in the nature of the assumption V. that Ampère's theory differs from others of this class. The second part of I. depends upon V. It is not true unless we assume that the force between the two elements is along the line joining them.

Ampère deduces the force between two elements of current from these principles as follows:—Suppose we have two elements of current of lengths ds_1, ds_2, traversed by currents of strengths $i\ j$ respectively; let us take the line joining the centres of these currents as the axis of x; let the plane of ds_1 and x be taken as the plane of xy; let $\theta_1\ \theta_2$ be the angles which $ds_1\ ds_2$ respectively make with the axis of x, η the angle which the plane through ds_2 and r makes with the plane of xy.

By Ampère's second proposition the action of ds_1 on ds_2 will be the sum of the action of

$$\begin{cases} ds_1 \cos\theta_1 \text{ or } \alpha_1 \text{ along } x \\ ds_1 \sin\theta_1 \text{ or } \beta_1 \text{ along } y \end{cases}$$

on

$$\begin{cases} ds_2 \cos\theta_2 \text{ or } \alpha_2 \text{ along } x \\ ds_2 \sin\theta_2 \cos\eta \text{ or } \beta_2 \text{ along } y \\ ds_2 \sin\theta_2 \sin\eta \text{ or } \gamma_2 \text{ along } z \end{cases}$$

Now, by proposition (1) α_1 cannot exert a force on either β_2 or γ_2, because it is in planes which bisect β_2 and γ_2 at right angles, so that the only component on which α_1 can exert a force is α_2. Let the force between these components be

$$\frac{a}{r_2}\alpha_1\,\alpha_2.$$

where r is the distance between the centres of the elementary currents.

In the same way we can show that the only component on which β_1 can exert any force is β_2. Let the force between these two elements be

$$\frac{b}{r_2}\beta_1\,\beta_2$$

Thus the force between the two elements $ds_1\ ds_2$ is

$$\frac{1}{r^2}\left\{ a\,\alpha_1\,\alpha_2 + b\,\beta_1\,\beta_2 \right\}$$

or substituting for $\alpha_1\ \alpha_2\ \beta_1\ \beta_2$ their values

$$\frac{1}{r^2}\left\{ a\cos\theta_1\cos\theta_2 + b\sin\theta_1\sin\theta_2\cos\eta \right\} i\,j\,ds_1\,ds_2$$

The proposition (III.) that the action of a closed circuit on an element of current is always at right angles to the element leads on integration to the condition

$$2a + b = 0,$$

so that the force between the two elements equals

$$\frac{a}{r^2}\left\{ \cos\theta_1\cos\theta_2 - 2\sin\theta_1\sin\theta_2\cos\eta \right\} i\,j\,ds_1\,ds_2.$$

From this we are able to find the force between any two circuits or parts of circuits. To find the force on a magnetic system Ampère used his principle that the magnetic action of an electric current was the same as that due to a magnetic shell bounded by the circuit and magnetised to the proper intensity. In this way Ampère gave a complete theory of the action of currents upon currents and upon magnets—in fact, a complete theory of all the effects produced by a current which were known when his paper was published.

* Report presented to the British Association Meeting at Aberdeen, September, 1885.

† "Ueber Ampère's Electrodynamische Fundamentalversuche," &c. Wien Ber. (11), 77, p. 109, 1878.

Digitized by Google

It is difficult to overrate the service which Ampere's theory has rendered to the science of electrodynamics. Perhaps the best evidence of its value for practical purposes is the extreme difficulty of finding any experiment which proves that it is insufficient. In spite of this, however, as a dynamical theory it is very unsatisfactory. If, as we are led to do by Ampère, we attach physical importance to elements of current, and regard them as something more than mathematical helps for calculating the force between two closed circuits, then we are driven to ask, not only what is the law of force between the elements, but what is the energy possessed by a system consisting of two such elements ? If we do this, and find this energy by calculating the amount of work required to pull the element an infinite distance apart, we arrive at the conclusion that the energy must depend upon the angles which the elements make with each other and with the line joining them. But if this is so, then the force between the elements cannot be along the line joining them, and there must in addition to this force be couples acting on the elements. For these reasons we see that Ampère's theory cannot give the complete action between two elements of current. What it does, and this for practical purposes is an advantage and not a disadvantage, is to give in most cases instead of the complete action between two elements that part of it which really affects the case under consideration. Before discussing cases, however, in which the terms which Ampère neglects might be expected to produce measurable effects, we shall, in order to compare the various theories more easily, proceed to consider other theories of the same class.

(To be continued.)

CORRESPONDENCE.

THE LAW OF THE ELECTRO-MAGNET AND THE LAW OF THE DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : The interesting paper of Prof. S. P. Thompson, in the January number of the *Phil. Mag.*, has suggested to me the following remarks :—

The theory of saturation of Lamont, as stated, starts from suppositions somewhat similar to those made by me, but differs entirely in its development. It seems to me that Lamont is wrong; and the development of his simplified assumption according to my view leads to an interesting result.

Both views may be represented by supposing the lines of force packed, like wires, into a hole of limited size, which can only receive a certain number. Both views regard the magnetic* conductivity as measured (so far as saturation is concerned) by the portion of the hole remaining unoccupied, or by what I have called the "defect of saturation."

Lamont, according to Thompson's account, then, regards the conductivity as the ratio,

$$\frac{\text{increment of magnetism}}{\text{increment of magnetising force}}.$$

Hence results a differential expression, the integration of which leads to the exponential law obtained.

But this is certainly not the conception of magnetic permeability or conductivity in general use, and it is not that which I employ. Conductivity is the ratio,

$$\frac{\text{magnetism}}{\text{magnetising force}};$$

the ratio of the quantities themselves, not of their increments.

If we make this change, we have, in Lamont's notation,

$$\text{conductivity} = \frac{m}{x} = k(\mathrm{M} - m).$$

M = maximum magnetism.
m = magnetism.
x = magnetsing force.
k = conductivity per unit defect of saturation.

Re-arranging the above expression, we see that it is identical with the form

$$m = \frac{\mathrm{M}kx}{1 + kx}$$

which Prof. S. P. Thompson seeks to derive by approximation from Lamont's exponential expression.

The above may therefore be now regarded as a rational formula, under the same limitations to which it is subject as an empirical one.

My formulæ for permeability (*Phil. Mag.*, February, 1885, p. 89) are

$$\mu = \mathrm{A}\,(\mathfrak{B}\propto - \mathfrak{B})\cos\delta$$
$$\delta = f\,\theta$$
$$\mathfrak{B} = \frac{k}{\rho}\;\frac{60^\circ - \omega\,\theta}{\sin.\,\theta}.$$

Here the A ($\mathfrak{B}\propto - \mathfrak{B}$) represents the

k (M − m) of Lamont, *mutatis mutandis.*

As soon as any attempt is made to represent values of μ (permeability) for the metal, such as are obtained from rings, the introduction of the cos δ, and of the two latter equations between δ, θ, and $\mathfrak{B}$, becomes indispensable. The object of these terms is to represent the initial rise of the permeability, and its passage over into what may be called the saturation fall.—Yours, &c., R. H. M. BOSANQUET.

St. John's College, Oxford.

* The subject of discussion in my theory is the permeability of the metal; in Lamont's, as stated by Thompson, the permeability of the magnetic circuit in a bar. Although I have myself formerly used *permeability* in both senses, I now think it best to speak of *conductivity* in the case of the bar.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Would you kindly draw attention to a mistake which appeared in your last issue in the report of the Society of Arts meeting, in which an assertion of mine as to the efficiency of secondary batteries was wrongly reported. I was reported to have said that in the tests made at our works with the experimental tramcar it was found that the efficiency in ampere hours was 75 per cent., and in watts 70 per cent., charging and discharging the cells considerably above the normal rate; whereas the figures I gave were 85 per cent. in ampere hours and not 75 per cent.

As the commercial efficiency of secondary batteries is commanding considerable attention, I trust you will find space for the above correction.—Yours, &c.,

BERNARD DRAKE, Managing Engineer.

Electrical Power Storage Company,
4, Great Winchester-street, E.C., Feb. 4, 1885.

THE RECENT TESTS OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : My attention has been called to a letter of Messrs. Woodhouse and Rawson, of London, published in your impression of December 11th, and elsewhere, in which they repeat a calumnious statement of a New York paper of June 13, 1885, but omit to add the contradiction by the Secretary of the Franklin Institute, published in the following number of that paper, of June 20, as follows :—

(From the *Electrical Review*, June 20, 1885.)

" Ed. Electrical Review :

" My Dear Sir :—Do me the favour to correct in your next what I take to be an unintentional mis-statement of my remarks regarding the "Electrical Tests" which appeared in last week's issue, and for which I must disclaim responsibility.

" I stated to your representative, as I have invariably stated to numerous other inquirers, that I could give little or no information regarding them, and that the proper person to

Digitized by Google

apply to for information was Mr. Tatham. Beyond this, I do not recognise the statements credited to me as my own.

"Yours truly,

"WILLIAM H. WAHL,

"Sec'y Franklin Institute.

"Philadelphia, June 16, 1885."

No other notice, as far as I know, was taken of the article, and the story died of its own absurdity.

The reason given by Messrs. W. and R. for reviving this defunct slander is, that rival makers of incandescent lamps are prodding them with the report of the judges appointed by the Franklin Institute to test the efficiency and duration of incandescent lamps.

It is true that the Swan, the Maxim and other companies did not enter their lamps for the tests for various reasons, but no one had any right or reason to apprehend that they would not be fair tests, and no one now has any reason to say they were not conducted fairly.

In the conduct of the tests the cardinal principle was to do right, and also to avoid all appearance of wrong-doing.

To this end a code was adopted and judges selected, with the full concurrence of the contestants, and nothing was concealed from the parties in interest. The contestants were invited to inspect and did inspect every step in the progress of the tests. Their experts compared the photometric measuring powers of the judges with their own.

I believe it would be impossible to find four men better equipped and experienced for their duties morally, mentally, and physically, than the four judges of these tests.

I was a daily witness of their work, and weekly progress reports of the tests were made to the Franklin Institute.

So much for the general indictment; and now for the particular complaint.

It is, *first*, that their lamps were tested without their knowledge or consent. *Second*, that their lamps were run at five volts above what they were labelled.

Two lots of their lamps were tested. The first lot, selected at random from a barrel of lamps belonging to the Van Depoele Company, were labelled 20 candles, 55 volts. They were tested and run at fifty-five volts. No. 9, with resistance cold of 106 ohms, lived longest, 715½ hours. No. 2, resistance cold 102 ohms, exhibited phenomenal brilliancy.

The complaint that this lot of lamps was entered without their knowledge or consent may be well founded.

The second lot of lamps was received through the Edison Company. I now learn that the origin of this transaction was as follows:—

At a meeting of the London Society of Arts, held December 3, 1884, Mr. Wm. H. Preece, F.R.S., read a paper upon "Electric Illumination," in which appeared the following language (see *Journal* of the Society of Arts, December 5, 1884, page 73):—

"The efficiency of the glow lamps has also been very considerably affected by the improvement made, for instance, by Messrs. Woodhouse and Rawson and by Mr. Bernstein.

"The efficiency of the Edison lamps means the consumption of energy at the rate of five watts per candle, but lamps are now being made which give an efficiency of two and a-half watts per candle with an equal life, which is equivalent to an immediate reduction of 50 per cent. in the amount of energy required to maintain the system alight, and therefore in the cost of production."

Whereupon, the Edison Company challenged Mr. Preece to produce such lamps and have them tested by the Franklin Institute, whose committee was preparing for the tests which afterwards were made.

Mr. Preece procured the lamps and forwarded them to the Edison Company, whose letter dated April 13, 1885, to Prof. Marks (who acted as an executive committee), says:—"Mr. Preece, the electrician of the English Post Office, has sent to Mr. Edison a number of Woodhouse and Rawson lamps. They are now in the New York Custom House. We have given directions to have them forwarded to you at the Electrical Exhibition in the original packing as soon as they are appraised."

At that time our test boxes were all occupied and our current employed.

Inside of the box, when received, was found a large label addressed "for Mr. Wm. H. Preece, 20 candles, 50 volts." The usual label of Woodhouse and Rawson was on every lamp, altered, however, so as to read as above, the figure 0 in the number 50 being written over an erasure. The resistances cold of all the lamps tested were nearly uniform, five at 100 ohms; two, each ninety-nine and 101 ohms, and one 102 ohms. [See Report, Table VI., page 38.]

These circumstances persuaded us that the lamps were not selected by chance.

They were tested and measured for horizontal and spherical efficiency upon the 7th May, both at fifty volts and at fifty-five volts, with the results shown in the following table, which I have made up from the original records:—

WOODHOUSE AND RAWSON LAMPS. (Second lot.)

Measurements of Horizontal and Spherical Efficiency, at 50 Volts and at 55 Volts, Compared. Made May 7, 1885.

Lamp No.	Volts.	Amperes.	Watts.	Candles Averaged.		Watts per spherical Candle.	Watts per Horizontal Candle.

Average	50·	1·0784	53·944	13·375	11·004	4·941	4·066
Average	55·	1·1777	64·770	22·127	18·296	3·557	2·955

Upon discussing these preliminary results, the judges found it impossible to follow the label. Twenty candles illumination could not be had with fifty volts, and they decided to raise the electromotive force for the following reasons:—There are three points of excellence in incandescent lamps—brilliancy, duration, and economy. The boast for these lamps is that they are brilliant and cheap. It would not benefit their reputation to test them with fifty volts, at which the preliminary tests show that they are both dim and dear, for the sake of increasing their duration, of which the remaining time of the tests, about 300 hours, would furnish no proof.

In this decision the judges were governed by a desire to do for the lamps what they thought the makers would do if they had been present and aware of all the facts. The judges made no concealments of what they did, nor of their reasons for it. They published the results of the tests with fifty volts, but not prominently.

It was out of kind consideration for the makers of the lamps that the judges raised the electromotive force, and it was out of a like consideration that they did not publish a table like the above.

These considerations Messrs. Woodhouse and Rawson have trampled under their feet, and have turned again to rend the committee.

I am unable to see the least shadow of unfairness in the proceedings of the judges, and I ask all those journals which have

Digitized by Google

published the letter of Messrs. Woodhouse and Rawson to publish this reply.—Yours, &c., W. P. TATHAM,
President of the Franklin Institute.

INSURANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A friend of mine some time ago was refused insurance against accidents by a well-known company simply because he was an electrical engineer. Of course this action shows great ignorance on the part of the Insurance Company, as an electrical engineer, in nine cases out of ten, is no more liable to accidents than an ordinary engineer.

This action on the part of the Insurance Company referred to reminds me of the fire offices in the early days of electric lighting. Many of them, not understanding the subject they had to deal with, charged 50 per cent. more premiums where houses were lighted by electricity, but when the Phœnix Fire Office went into the matter and found that with proper precautions the risks were no greater in using electricity than with gas, and reduced their premiums accordingly, all the other companies had to follow.

As it is a matter of some moment to us, as electrical engineers, that we should be covered against accidents, I think it would be a great favour if you would allow such information to be given through your columns (either from the companies themselves, or those who *may be* insured) that will enable us to know where, and at what cost, we may be insured. I should like also to know what restrictions, if any, are made with respect to the use of high tension currents.

I think, sir, if you were to express your opinion on the subject of electrical engineers' risks, stating what you consider the greatest E.M.F. that should be allowed as safe, the insurance companies would probably be more ready to accept our proposals, and no doubt on better terms.

Trusting we may have some information on this point, I am, &c., INSURANCE.

THE DYNAMO AS A GENERATOR AND A MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Mordey's letter in your current number, I beg to say that I quite understood that the experiments were made with a shunt-wound dynamo; and I think my letter shows this.

I am, however, unable to understand how the question is affected by the fact of whether Mr. Mordey mentioned a compound dynamo or not.

Mr. Mordey stated in his paper, first, that he had obtained a constant speed, under conditions that were impossible, and then that the speed followed the load inversely, as it must do under the circumstances.

I certainly thought that Mr. Morley intended to refer to the compound dynamo in the first paragraph quoted in my letter, as that is the only form of machine which does maintain a constant E.M.F. at terminals with varying current but at constant speed. And my objection to Mr. Mordey's use of the term "constant field" is as correct for the shunt-wound dynamo as for the compound wound; but with this difference, that where the field in the compound-wound machine increases in strength as the current increases, in the shunt-wound dynamo it decreases. The series dynamo is the only one in which the field is constant; and there the requirements of a varying load are met by variations in the speed of the armature. Where, as in the Edison-Hopkinson dynamo, the resistance of the armature is very low indeed, the shunt dynamo becomes *almost* self-regulating, and the field is *almost* constant; but no shunt-wound dynamo can be so perfectly self-regulating as the compound-wound dynamo, if properly compounded, so long as its armature has a resistance appreciable to the strongest current it will have to carry. Nor can its field be constant except with no resistance and no self-induction in its armature. I am pleased to find that Mr. Mordey has raised the commercial efficiency of the Victoria motor to 80 per cent. I presume that this has been done since he wrote his paper. Unfortunately, his experiments do not show this, unless the unascertained loss in transmission was very serious indeed.

Mr. Sayers' figures, which agree with my own calculations, show that the highest efficiency obtained was 71 per cent., which is *not* commercial efficiency, but something more, inasmuch as no account has been taken of the power absorbed by the field-magnets.

I note that Sir David Salomons, in his letter on "Motors," has given us a very valuable hint for the future.

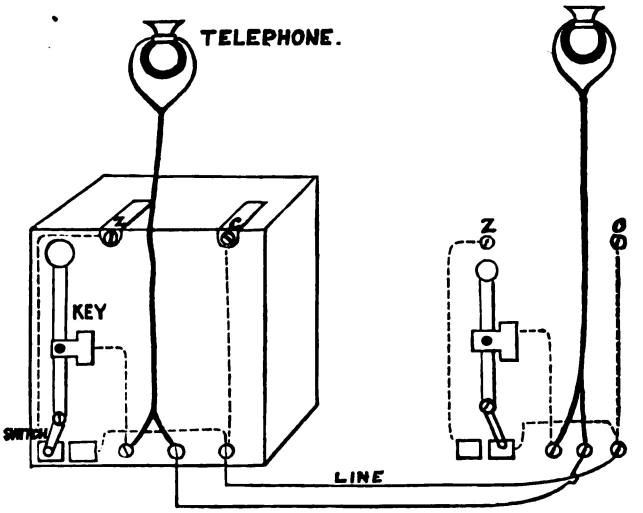
Mechanical engineers always meet us, when we propose that they should run their machines by means of the motors instead of shafting, with the objection that the loss by transmission is too great. "You lose 50 per cent.," they say, "if the machine to be driven is only five yards from the engine," and though your apparatus may do very well for long distances, it "would be absurd to use it in a factory where the distances are so short; and we can transmit by means of shafting and belts with a very much smaller loss." As Sir David has shown, they forget the fact that if only part of the machinery is working, still the whole of the shafting has to run in most cases; whereas, with electro-motors, each machine takes just its own current and no more.

I heard of one large factory in Lancashire where 100 horse-power was allowed for the shafting alone. Fancy the whole of that running, as a *reductio ad absurdum*, to turn a few machines requiring only 2 or 3 horse-power.—Yours, &c.,
SYDNEY F. WALKER.

TELEPHONES AND THE MORSE CODE IN MILITARY OPERATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On receiving *The Electrician* of November 27th, 1885, I noticed a communication from J. H. A. Macdonald, Edinburgh, concerning the use of telephones and the Morse code in military operations.



I have used this instrument and code as a means of temporary communication for distances up to two kilometres. I attach a sketch of connections as I used them. Fig. 1 represents a small battery of 1, 2, or 3 small Leclanchés in a well-closed box, 5 x 2 x 2in., or larger, as 1, 2, or 3 cells are used; on the box is fixed a key for breaking circuit, at the back of box is a hook for securing it to manipulator's belt. Each manipulator is supplied with box complete, but as battery at one end only is in use, key is supplied with a switch to put battery in or out of circuit, according to previous arrangement.

Fig. 1 shows battery switched in, whilst Fig. 2, at other end of line, has only circuit breaker in use.

With this instrument secure on right side of belt, manipulator keeps telephone to left ear, and uses right hand for speaking.

If you think this worth anything I shall be glad if you will publish it.—Yours, &c.. JACARE.

Fortaleza, 7th January, 1886.

THE TELEPHONE QUESTION IN AMERICA.

To understand the present position of telephone affairs in America is difficult for those who are not acquainted with the ways of the United States Patent Office and of American Courts of Law; how "interferences" can be declared between rival patentees; how local "injunctions" can be moved for and ordered by the judges in the various States of the Union; how "evidence" can be brought before the courts in a manner which the laws of evidence in this country would utterly exclude; how patent law is often construed with the view of giving "protection" to the Yankee inventor as against the prior inventions of a foreigner; and how, in general, the methods of wasting time in the law's delays are even more abundant than in the old country.

It is amongst such conditions as these that the promoters of the American Bell Company have worked. They have bought up the interests of one rival who was "in interference;" ompromised with another; obtained a local judgment against another; used this judgment against the next comer, and so redoubled their forces upon the next; every decision in their favour having helped to widen their claims and to embolden them in their pretensions. For a good many months it has been evident to careful observers on this side of the Atlantic that such a state of things was becoming intolerable. At last it was whispered that the peculiar legal machinery of the United States, which enables a suit to be brought in the name of the United States to test the validity of an important claim, would be put in motion against the American Bell Company. After several puzzling manœuvres, the meaning of which does not appear upon the surface, on the application of a United States District Attorney of Baltimore, the Secretary of the Interior Department at Washington, Mr. Lamar, has decided that a suit of this kind shall be instituted.

On learning this decision, Prof. Graham Bell took the step of addressing a letter to the Attorney-General of the United States. As this officer will be the virtual judge as to whether there be a *primâ facie* case or not, the sending of a letter to him constitutes in itself a most extraordinary circumstance, and one which, had it occurred in England, would be regarded as a serious contempt of court, punishable by heavy penalties as being a gross attempt to influence the Court before the hearing of the case. The letter itself is scarcely less extraordinary. It is distinctly angry in tone, and personal in several respects. It contains many *ex parte* statements such as no court could for a moment accept, even if the communication were itself in order. Far better had it been for Prof. Bell to have kept silence at this stage, rather than appear to endeavour summarily to burke a judicial investigation of his claims. His letter, which, though sent to England as a private communication, has been printed in full by a contemporary, consists of three principal parts: A statement of certain decisions of local courts, and of the Patent Office to the effect that the art of transmitting speech by electricity (which entire "art" is now claimed by Bell) was not to be found in any of the publications relating to Philipp Reis's telephones; a statement, personal and largely *ex parte*, respecting the inventions of his rival, Mr. Elisha Gray; and a still more personal statement about certain parties, whom Bell styles "convicted infringers," whom he alleges to have instigated the present suit. With these last persons we have no concern. It matters little who the individuals may be that have brought the issues to a head; our interest is with the issues themselves. With respect to the claim of Bell to the entire "art of transmitting speech by electricity," we have much more to do. That such a prodigious claim could be founded on the very narrow language of the original Bell patent is a monument to the adroitness of New England lawyers. To sustain such a claim an inventor must show not only that he is the first, but that he is the *sole* inventor of the art. He must show that there is no other way of doing it than that which he invented. And it seems to us that this is a task which is beyond human capability. Was Bell the first? Is his method the only possible method of transmitting speech by electricity? These are the two essential points. He has himself named Philipp Reis—Reis, the deceased schoolmaster, who, to use Bell's own words, "entered the field of telephonic research" in 1861, and died, all too soon, in 1874. Thanks to those who have been most active in rescuing Reis's words and works from undeserved neglect, we now know how much he had done. In 1861 he wrote that he had "not yet succeeded in transmitting human speech with a distinctness to satisfy every one"; nevertheless he persevered, and in 1863 he was able to write: "I assure you that when you visit me here I will show you that you are in a position quite to understand words also." Others who bought Reis's telephones allege that they were able then, and are able now, to use them to transmit speech. These facts if established as against the claim to the whole "art," will go far to upset Judge Gray's decision, which was the first of so many others in local American suits, that "a century of Reis would never have produced a speaking telephone." Bell has also named Elisha Gray, but seems to forget that at the Paris Exhibition of 1878, it was to Elisha Gray, not to Graham Bell, that the award was made for the invention of the telephone.

Secondly, is Bell's method of transmitting speech by electricity so absolutely comprehensive as to preclude the possibility

Digitized by Google

of any other? Not even a United States Court, be it ever so wise or just, can set limits to inventive genius and say, "thou shall not invent." Let us inquire what Bell's method, *as claimed by him in 1876*, was. The method was clearly set forth in three claims as essentially one of "producing undulations in a continuous voltaic circuit." The only method previously known was that of Reis, whose method consisted in opening and closing the voltaic circuit in proportion to the vibrations, by a transmitter having a diaphragm combined with a loose contact arrangement, which can be best described in modern language as a metal microphone. The advocates of Reis's claims have not failed to point out that the words "make-and-break," so often attributed to him, were never used by Reis, and that the action which he described as opening and closing the circuit differed in degree only, not in kind, from the action in every modern battery transmitter such as the "Blake" instrument. As a matter of fact, throughout the United States, though Bell's later form of instrument is used as receiver, Bell's instrument is not used as a transmitter; his instrument and his method have for that purpose been abandoned. The transmitter actually used is the Blake, and its method of operation closely resembles that of Reis; it opens and closes the circuit of a battery in proportion to the vibrations. Reis's method of transmitting speech by electricity being previously known, it is clear that if Bell's claim of 1876 does not include Reis's method, it excludes it. Such at least is the contention of Reis's friends, and, according to them, if Bell's claim includes Reis's method, then Bell's claim is bad. If Bell's claim excludes Reis's method, then it is useless for the advocates of Bell to claim the entire "art" of electric transmission of speech.

There are other issues of course besides this. There is the question whether such undulatory currents as Bell described in 1876 can possibly convey anything more than musical and vocal sounds. It is asserted by some that to transmit perfect articulate speech with all its consonants and abrupt turns of inflexion, an intermittent and not an undulatory current is absolutely necessary. This is again an issue too wide to be traversed here, but it is one of the many questions which will presently be brought under review in the fierce light that beats upon a law suit. Our readers will doubtless await the hearing of the suit with an interest the more eager because of the magnitude of the claim which has been so elaborately built up, and of the hitherto unchecked triumph of the monopoly which controls the telephone from the Atlantic to the Pacific. We have hitherto been among the foremost to do full justice to Prof. Bell's invention, but we are unable to follow him in the extravagant claims now put forward in his letter to the United States' Attorney-General, or to sympathise with the angry and aggressive tone which pervades it.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: *The Electrician* of the 22nd and 29th inst. having been published without any reply appearing in them from Dr. Stone to my letter published in *The Electrician* of the 15th inst., it is now my duty to expose the fallacy of the imputations Dr. Stone emitted against the electric boy in his letter in *The Electrician* of the 8th inst. Dr. Stone's allusion to dry climates, like some part of America, and electricity produced by walking on carpets therein, is altogether erroneous as regards the case of the electric boy. When I saw him the weather was wet and of the most unfavourable kind for the manifestation of electricity by such means. Again, the piece of carpet in question was not more than two square yards in extent, so that there was no room for such an amount of walking as would be necessary for such an effect to be produced. Again, if the electricity manifested in the boy's body came up from his feet, his legs, when touched, ought to have given a shock stronger, or as strong as that obtained from his body; but the opposite of this was the case. I felt no shock when I touched his legs, but received a shock when I touched the upper part of his body, and especially when his tongue was touched. These facts are utterly inconsistent with Dr. Stone's insinuations, and, on the contrary, the facts I have just stated of my own experience with the electricity manifested from the boy's body cannot be explained on the supposition that the boy was electrified from a source external to his own body. I particularly request Dr. Stone's attention to these facts. There is a most important source of electricity in the human body, which, as far as I am aware, has never been referred to by any writer on electricity, namely, the breath we draw into our lungs. It consists of oxygen, nitrogen, ozone, as commonly stated. But each of these substances contains a goodly quantity of electricity which at each breath is taken into the lungs, and although a portion of it will go out again by the expired breath, still a large portion of the inhaled electricity must go to help to keep up the internal heat of the human body. And if our skins were perfect non-conductors of electricity and we did not perspire, electricity would accumulate in our bodies to an inconvenient extent. Since this correspondence began, a scientist has informed me that the electric boy's case is not a solitary one. There are other persons in whose bodies electricity is developed in a mysterious way; but private individuals do not like their electrical infirmities made the subject of public observation.

As to your correspondent "Hamlet," the contents of his letter are so fabulous that they bear, on the face of them, their own condemnation.—Yours &c.,

8, Merchiston Park, JAMES JOHNSTONE.
Edinburgh, 30th January, 1886.

THE CALORIMETRIC MEASUREMENT OF INCANDESCENT LAMPS.*

BY WILHELM PEUKERT.

An important advantage of the electric light as compared with other systems of illumination, lies in the relatively far smaller amount of heat developed by the former for an equal intensity of light. Accurate calorimetric measurements of incandescent lamps have not yet been made public, and the results obtained with such lamps are therefore given below, whilst I reserve for a future occasion a report on corresponding experiments with arc lamps. The experiments may be of interest from another point of view, as they enable us to form a conclusion as to the economical utilisation of the electric energy consumed by a lamp. The working of a lamp, other circumstances being equal, must be considered the more rational the greater the proportion of the electric energy absorbed which reappears in the amount of light generated.

The experiments have been conducted in the electro-technical laboratory of the Technical High School at Hanover, and it is my pleasant duty to put on record my obligations to Prof. Dr. W. Kohlrausch, who placed at my disposal the necessary apparatus, as well as to Herren Caspari and Ottesen, who took part in the measurements.

The determination of the heat evolved by the incandescent lamps was effected by means of a calorimeter. This consisted of a large beaker of thin glass, which was filled each time with a quantity of water carefully weighed.

The incandescent lamp in question was immersed in the water, which was continually kept well mixed by means of a simple agitator, and possessed a uniform temperature. This temperature was observed on a thermometer placed in the calorimeter, graduated in tenths of a degree centigrade. The calorimeter was fixed on a heat insulator, and to avoid as far as possible losses of heat to the surrounding air, a very slight difference between the respective temperatures of the air and the water was maintained during the experiments, amounting

* From *Zeitschrift für Elektrotechnik*.

Digitized by Google

to 5° C. in one case only, and being in others always below this maximum value. That, in fact, the increase in the temperature of the water was little affected by the temperature of the air, is shown by the following rises of temperature taken at equal intervals of time, which in few cases differ by 0·1° C. The temperature of the work room increased only by 1° C. during the entire time of the investigation.

To ascertain the absorption of light, every lamp was determined photometrically, both when exposed freely and when placed in the calorimeter. As a standard of comparison I used Von Hefner-Alteneck's normal flame. The current was furnished by a Schuckert compound machine driven by a well-regulated Otto gas engine, so that the potential difference at the lamps, measured with a Siemens and Halske torsion-galvanometer, remained very constant. The strength of the current was determined with the same instrument by ascertaining the difference of potential at the ends of an accurately known resistance.

The results obtained are as follow :—

Siemens and Halske Incandescent Lamp.—The lamp worked with a potential difference of 98 volts and a strength of current of 0·554 ampere, which values were found as the mean of all the observations executed simultaneously, which, as already mentioned, differed little from each other.

The calorimeter contained 2,471 grms. of water, and if we calculate the value of the vessel in water as 79·1, the total quantity of water was 2,550·1 grms.

The observations were made at intervals of three minutes.

This rise of temperature of 0·7° in three minutes gives an hourly development of heat of 35·7 kilogram calories.

Thermometer.	Rise of Temperature.
14·9°	0·6°
15·5°	0·7°
16·2°	0·8°
17·0°	0·7°
17·7°	0·7°
18·4°	Mean......... 0·7°

The lamp when burning freely gave a light of 8·8 normal candles, and when in the calorimeter, 8·1.

Edison's Incandescent Lamp.—Potential difference at the lamp = 93·6 volts ; strength of current = 0·963 ampere.

Total quantity of water, 2,791·1 grms.

Observations at intervals of five minutes.

Thermometer.	Rise of Temperature.
14·65°	1·65°
16· 3°	1· 7°
18· 0°	1· 6°
19· 6°	1· 7°
21· 3°	1· 6°
22· 9°	Mean .... 1·65°

The rise of temperature of 1·65° in five minutes gives an hourly development of heat of 55·26 kilogram calories.

The lamp, burning free, gave a light of 16·9 normal candles, and in the calorimeter 14·4 normal candles.

Swan's Incandescent Lamp.—Potential difference = 76 volts; current = 2·552 amperes. Quantity of water, 2,435·1 grms. Observations every two minutes.

Thermometer.	Rise of Temperature.
15·1°	1·7°
16·8°	1·7°
18·5°	1·7°
20·2°	1·7°
21·9°	1·7°
23 6°	Mean .... 1·7°

A rise of temperature of 1·7° in two minutes represents an hourly development of heat of 124·19 kilogram calories. The lamp, burning free, gave a light of 30 normal candles; in the calorimeter, of 28·2 normal candles.

Bernstein's Incandescent Lamp.—Potential difference = 48 volts; current = 3·934 amperes. Total quantity of water, 2425·1 grms. The observations were made at intervals of two minutes.

Thermometer.	Rise of Temperature.
15·5°	1·1°
16·6°	1·1°
17·7°	1·1°
18·8°	1·1°
19·9°	1·1°
21·0°	Mean......... 1·1°

The rise of temperature of 1·1° in two minutes gives an hourly development of heat of 80 03 kilogram calories.

The lamp, burning free, gave a light of 52·1 normal candles, and in the calorimeter 51 normal candles.

Concerning this lamp, it must be remarked that the quantity of heat as determined is possibly too low, since losses of heat were not absolutely excluded in the experiment, owing to the construction of the lamp, which could not be entirely immersed in the water.

As the electric energy consumed by an incandescent lamp is converted into heat and light only, the portion of the total work of the current equivalent to the light evolved may be determined approximately, if not with absolute accuracy. An experiment may here be mentioned which was performed with an Edison A lamp.

It was placed in the calorimeter along with a vessel of thin sheet copper, so that light and heat were kept back. The amount of heat determined in this case agreed to 2 per cent. with that calculated from the potential difference and the strength of the current.

If we may assume that in the first-mentioned experiments the entire heat developed was absorbed by the calorimeter, and that the heat lost in the air was but small, which, approximately speaking, was the case, we obtain from the quantity of light evolved by the various lamps the following equivalent quantities of heat:—

Siemens and Halske's Lamp.

	Kilog. calories.
Hourly quantity of heat corresponding to the work of the current	46·98
Heat equivalent to the light evolved	11·28
Hourly heat per normal candle	1·393

Consequently for this lamp, with reference to the absorption of light, the heat evolved hourly may be estimated at 37·73 kilogram calories, corresponding to 74 per cent. of the total work of the current, so that 26 per cent. of the current falls to the quantity of light evolved.

Edison's Lamp.

	Heat units.
Hourly amount of heat corresponding to the work of the current	78·01
Heat equivalent to light evolved	22·75
For normal candle hourly	1·58

Thus the heat evolved hourly by this lamp may be taken as 51·31 heat units. Hence 66 per cent. of the work of the current are expended in heat and 34 per cent. in light.

Swan's Lamp.

	Heat units.
Hourly amount of heat representing work of current	167·86
Heat equivalent to light evolved	43·67
Therefore for a normal candle hourly	1·549

The heat evolved by this lamp hourly is 121·4 heat units. Hence 72 per cent. are expended in heat and 28 per cent. in light.

Bernstein's Lamp.

	Heat units.
Hourly amount of heat representing work of current	163·43
Heat equivalent to light evolved	83·4
Therefore hourly per nominal candle	1·635

The hourly heat for the lamp is therefore 78·24 heats units. Of the total work of the current, 48 per cent. is expended in

Digitized by Google

heat and 52 in light. This high percentage may be due to the circumstance that, as already mentioned in the experiments with this lamp, considerable losses of heat were not excluded. Indeed, the percentages of the work of the current assigned here to the production of light can only be regarded as the superior limit. Experiments more precise than those here described may possibly yield lower values.

If the hourly quantities of heat per unit of light are calculated into their equivalents of mechanical work, we obtain the mechanical work per second equivalent to a unit of light (and therefore for a magnitude which may be regarded as the mechanical equivalent of this light), the following values: 0·16 kilogrammes (Siemens and Halske), 0·18 (Edison), 0·18 (Swan), and 0·19 (Bernstein). These values show a sufficient agreement for the experiments just described, but can by no means be regarded as giving an accurate value for the mechanical equivalent of light. Indeed, the experiments were not conducted with any such intention. These results are merely mentioned here as a corollary of the experimental conclusions, perhaps not quite devoid of interest.

For the sake of comparison, the amounts of heat obtained with other sources of light are tabulated along with those found with incandescent lamps. The hourly quantities of heat evolved are :—

	Heat units.
Incandescent lamps. Siemens and Halske...	427
" " Edison	355
" " Swan	430
" " Bernstein	153
Gas. Siemens' regenerative burner	1,500
" Argand	4,860
" Two-hole burner	12,150
Petroleum. Round burner	3,360
" Small flat burner	7,200
Solar oil. Schuster and Bauer's lamp	3,360
" " Small flat burner	7,200
Rape oil. Carcel lamp	4,200
" " Reading lamp	6,800
Paraffin candles	9,200
Spermaceti candles	7,960
Wax candles	7,960
Stearine candles	8,940
Tallow candles	9,700

The above-mentioned experiments have led me to undertake a close investigation into the conversion of electric energy into light and heat, both in incandescent lamps and arc lamps. A memoir on this subject will shortly appear.

DYNAMO TESTS.

(Continued from page 216.)

Power Measurements.

The general principle of the Tatham dynamometer is shown in Fig. 6. The power applied to the shaft on which the driving pulley D is fixed, is transmitted to the pulley B, to whose shaft the machine to be tested is coupled, by an endless belt, which passes over D, under the stretching pulley S, over the weighing pulley W, under B, over the second weighing pulley W, under S, back to the place of starting. Each of the weighing pulleys W is supported in a cradle, the outer end of which is pivoted on the knife edge F, while the inner end is supported by the link L C. The upper ends of the two links are fastened to the scale beam F, P at equal distances from and on either side of the fulcrum F.

To calculate the power applied to the pulley B, it is necessary to know three things: The difference of tension of the belt on the two sides of B; its effective diameter; and its number of revolutions. These will be discussed in order.

The scale beam is acted upon through the links L C, fastened to the cradles of the weighing pulleys W. The tensions of the belt on the outer faces of these pulleys have no effect on the beam, since the line of effort of the belt passes through the knife edges F. The only forces, then, that act on the beam are the two tensions of the belt on the inner faces of pulleys W, *and these are the tensions on the two sides of* B; and the links being at equal distances on either side of F, the *difference of the tensions* is recorded on the beam.

The scale beam was of steel, graduated by Brown and Sharpe into 600 divisions. With the weight used each division meant one half-pound. A small poise travelling on the weight allowed readings to be taken to $\frac{1}{200}$th of a pound.

There were two adjustments to the cradles. In the first, the axis of the pulley W was moved by micrometer screws to such a position that the line of effort of the belt passed through the knife edges of the cradle. To show this, the pulley was chocked, a short piece of the belting hung on its outside face, and weights placed in a pan hanging to the belt. When there was no effect on the scale beam, the adjustment was accomplished.

The second adjustment determined the position of the knife edge to which the links were connected. This was moved until the beam weighed about 250 pounds correctly to within one-twentieth of a pound.

The pulley B was calculated to deliver 6·6 feet per revolution, but the belting used was thicker than was at first intended, and the value 6·6 should be increased by one-fourth per cent. The effective diameter of the pulley, including the thickness of the belt, was measured directly, and also calculated from the the length of belt delivered by five turns of the pulley. For the latter measurement, two steel points, one of which was fitted with a micrometer screw, were fixed on a wooden rule, and their distance apart accurately determined on a standard scale. Marks were made on both the pulley and belt opposite to fixed pointers. Five revolutions were given the pulley, and the length of belt that passed the pointer was measured by the rule with the steel points, any margin being taken off by a pair of compasses. The pulley was turned both ways and the effect of stretching eliminated.

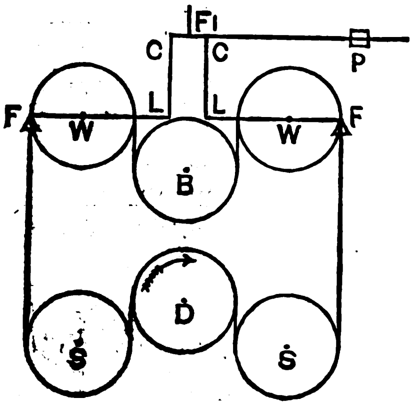

Fig. 6.

The two methods checked very closely, and gave for the delivery of the pulley

6·6 (1·0025) feet per revolution.

A very ingenious mechanical counter registered the number of revolutions. Observations could be taken each minute, and the counter recorded continuously to 1,000,000 revolutions.

Having the difference of tension on the two sides of B, its delivery per turn, and number of turns per minute, the horse-power is calculated as follows :—

$$\text{Horse-power} = \text{divs. scale beam} \times \text{No. revs.} \times \frac{6\cdot6\ (1\cdot0025)}{2 \times 33000},$$

$$\text{Horse-power} = 1\cdot0025 \left\{ \frac{\text{divs. scale beam} \times \text{No. turns per min.}}{10,000} \right\}$$

It will be seen that the only part of the friction of the dynamometer that appears in the readings is that due to the bearings of the pulley B. By the principle of Morin, that the sum of the tensions on the two parts of the belt is constant, this friction should be the same whatever the load. In getting the power applied to a machine, after the measurements have been made with the machine coupled to the dynamometer, it was uncoupled and the dynamometer run at the same number of revolutions, the scale beam observed, and its reading subtracted from the reading when coupled.

Digitized by Google

To avoid the uncertainty of loss due to belting, the shaft of the driven pulley B was coupled directly to the dynamo by a universal coupling. It was assumed that this would allow for any slight inexactitude in lining the dynamo and the dynamometer shafts, but it is doubtful if it was of much value at the high speeds used for the tests.

The figure of the dynamometer (Fig. 7) gives a view of it as used in these tests. The automatic recorder for the scale beam, shown in the figure, was not used. In making observations, the number of revolutions and scale beam were read each minute, usually for ten minutes. The means of the two sets were multiplied together, the product divided by 10,000, and a correction of one-fourth per cent. applied, as given in the formula.

The delicacy and range of the dynamometer were both very great. On one occasion the power absorbed by a single Weston mammoth lamp was accurately measured, while the slightest variation of the load could be at once detected. During a test, the scale beam usually floated steadily, the slight and rapid jar caused by running served to limber up the weighing apparatus and render it especially sensitive. Indeed, it would be hard to fix a limit to the accuracy with which the observations could be taken.

Mr. Tatham has published a paper* giving the principles involved in the dynamometer, and describing its various modifications of form.

The engine used was a 10in. by 20in. Salem Buckeye. Its governor adjustment could be readily varied from 100 to 200 revolutions. The speed, under the steady load of a dynamo, was very uniform.

A steel boiler, loaned by the Baldwin Locomotive Works, was used. It could safely carry 150 pounds per square inch and develop eighty horse-power.

* *Journal* Franklin Institute, Dec., 1882. Vol. CXIV.

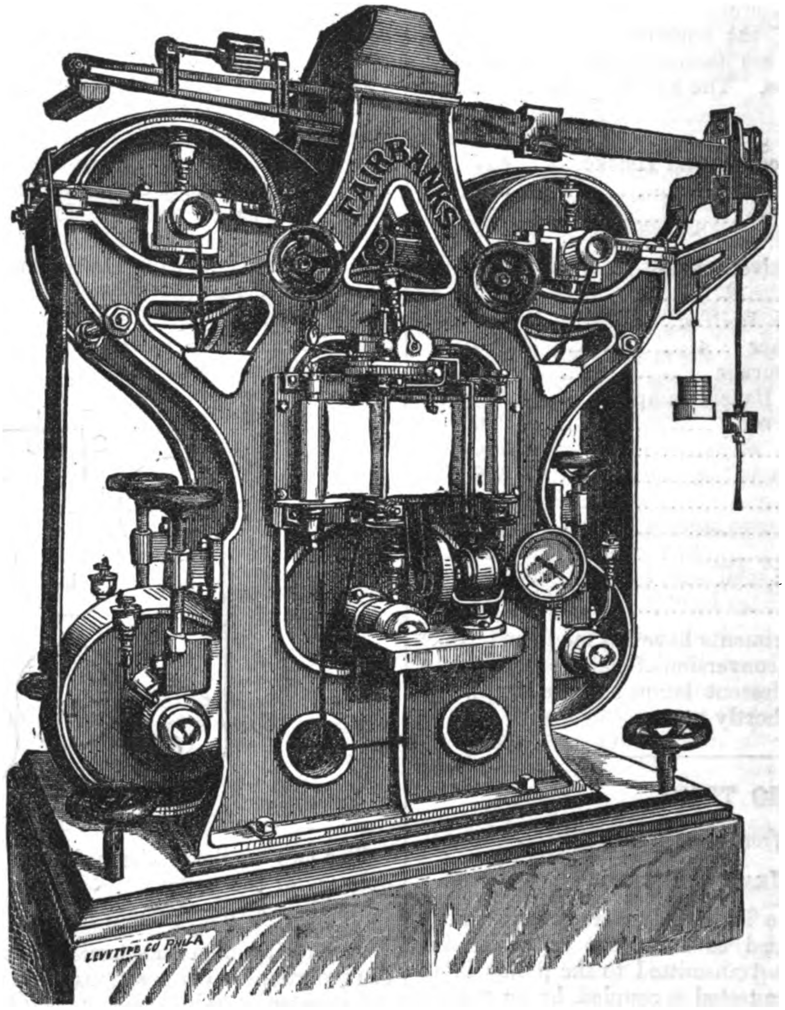

Fig. 7.—The Tatham Dynamometer.

Checking the Dynamometer.

In order to make the tests absolutely, as well as relatively accurate, it was decided to check the work recorded by the dynamometer against an amount of work calculated from the mechanical equivalent of heat.

To do this, a calorimeter was constructed.

It was of wrought iron 3ft. long by 3ft. in diameter, with V-shaped projections riveted inside the shell. The paddles, 30in. long by ½in. thick, were keyed to the shaft and moved between the V's. One end of the shaft passed through the end of the calorimeter, and was coupled to the dynamometer. In the experiments but one paddle was used, 700 revolutions absorbing about forty-five horse-power.

Two different methods of experiment were employed; first, with a constant weight of water and an increasing temperature; and second, with a constant temperature and a continuous flow of water through the calorimeter.

First Method.—In the first method, the calorimeter was filled and its water equivalent found, the engine was then started, and the rise of temperature noted, and the dynamometer observed. The mechanical equivalent was calculated from the work recorded by the dynamometer, the water equivalent of the calorimeter and the rise of temperature, the necessary corrections being applied to the latter. The value thus obtained was compared with the values of Joule and Rowland.

In getting the water equivalent, the calorimeter was first weighed empty, and then when filled with water. The difference gave the weight of the water, and the water equivalent of the iron was calculated from its weight and specific heat.

(To be continued.)

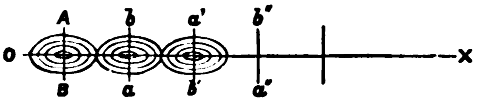
CLERK MAXWELL'S ELECTRO-MAGNETIC THEORY OF LIGHT.*

BY MISS J. M. CHAMBERS, B.SC.

The following is how I have supposed the "series of oppositely directed magnetisations and electromotive forces" of C. Maxwell's theory to arise. I do not in the smallest degree pretend to comprehend his mathematics, and it is only from his verbal explanation that I have formed the following conception of what his meaning is.

Suppose we have a straight linear conductor, A B, in which from some cause or another a quantity of electricity is continually bobbing up and down. We know that the lines of magnetic force, arising from these alternate up and down currents, will be circles having the linear conductor for axis. Suppose we have a row of these conductors parallel to one another.



When the magnetic force lines cut the next conductor *ba*, an electromotive force of opposite sign to that in A B will be engendered, in accordance with Lenz's law, and a current will ensue which will in its turn be surrounded by magnetic force-lines. When the current in A B is reversed, the induced one in *a b* will be so too.

The action of *a b* on *a' b'* will be the same as that of A B on *a b*; and the same effects will be propagated along the whole line of molecules. We have here the electromotive forces and the magnetic forces acting in directions perpendicular both to one another and to the direction of propagation, O X, as the theory requires. Of course this explanation would be for a plane-polarised ray.

It seems to me that this explanation presents to the non-mathematical mind, in a tangible form and in accordance with well-known electrical phenomena, what may be the manner of production of the "series of oppositely directed magnetisations and electromotive forces."

It is not necessary that the conductors should be linear; we may suppose them globular and touching one another, without interfering with the idea of the action above explained. We may, in fact, suppose them merely portions of the æther.

Perhaps it may be objected that my conductors are not circuits; but a current which keeps passing backwards and forwards from a condenser acts in precisely the same manner as a true current (*see* Art. 776 Maxwell, &c.), and why not also without the condenser?

Note.—Perhaps this idea is nothing new, and has occurred to others as well as to me. I have been told, however, that C. Maxwell himself would never precisely define the action by which he supposed light and electromagnetic induction propagated.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

PRESIDENTIAL ADDRESS.

BY PROFESSOR D. E. HUGHES, F.R.S.

Before commencing the subject of my address this evening, I desire to express my sincere thanks to the members of the Society of Telegraph-Engineers and Electricians for the great honour they have conferred on me by electing me as their President, and to assure them that I will do all in my power to aid and promote the interests of our Society, which are those of applied science in one of its highest branches. It is the custom in our Society that the elected President should open the Session by an address containing a general review of the present state of Electrical Science, or researches in some special branch which may be of interest. I have chosen the latter, as it enables me to present to you some researches which I have not yet published, and I propose to present these in the form of a paper rather than an address, in order to allow our members the opportunity of a full discussion on the subject, which I hope may bring forth many new facts in their possession.

The subject which I have chosen is—

THE SELF-INDUCTION OF AN ELECTRIC CURRENT IN RELATION TO THE NATURE AND FORM OF ITS CONDUCTOR.

Induced or secondary currents in a near but independent circuit were discovered by Faraday in 1831; and the phenomenon of the self-induction of an electric current in its own wire was observed by Henry in 1832, and traced to its cause in 1834 by Faraday, who proved that on sending a current through a wire a momentary induced current in the opposite direction is evoked in its own wire; also that, on the cessation of the primary current, a second induced or "*extra current*" is excited in the direction of the primary. The effect is greatly augmented when the wire forms a coil, as we then have in addition the reaction of superposed currents; but the effect exists to a great extent even when the wire forms but a single loop, or a straight wire with the earth forming the returning portion of the loop, as in all telegraph lines. It has been generally supposed that the nature of the molecular condition of the metal through which the primary current passed exerted no influence upon the extra currents except that due to its resistance. I have previously pointed out* that for induced currents "the rapidity of discharge has no direct relation with the electrical conductivity of the metal, for copper is much slower than zinc, and they are both superior to iron." This led me to make a study of these extra-currents, for which purpose I constructed a special induction bridge, in order to measure both the primary and its extra-currents separately at the instant of action.

Induction Bridge.—This instrument is a combination of a portion of my "Induction Balance," with a "Wheatstone Bridge." The resistance of the wire is measured and balanced by the bridge; the induced or extra-currents are measured and reduced to zero by an equal opposed induced current from the induction balance.

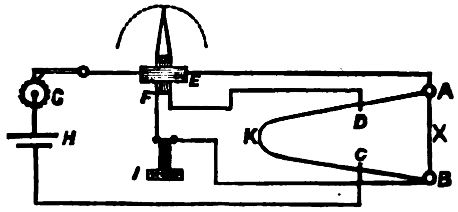

FIG. 1.

The above diagram shows the electrical communications. The bridge consists of a single German silver wire (0·25 mm. diameter, 1 metre in length, of 4 ohms resistance) running from A to K, returning to B. The wire is stretched and sustained upon two wooden arms articulated at K, by means of which the terminals A B can be more or less separated as desired. The wire to be tested, X, is joined at A and B, thus completing the closed circuit of the bridge. The external communications are shown, A being connected to the primary coil of the sonometer E, and through it to the spring of the interruptor or rheotome G, the interrupting wheel being connected to the battery H, and thence to the bridge at C. The wire from B passes through the telephone I to the secondary coil F, returning to D.

Great care has to be taken in the construction of the bridge, so that it shall be as free as possible from induced or extra-currents; and for this reason we cannot employ or introduce resistance coils. The resistance of the wire X is balanced by sliding the communications D and C. It is evident that if all the arms of this bridge are equal in resistance and inductive capacity, there will be silence on the telephone; but if A B be slightly stronger or weaker in inductive capacity, then we may be able to balance its resistance, but not its induction, as we shall then have a slight or a loud continuous sound due to the differential extra-currents in the arm A B. These are compensated by the introduction in the circuit of the telephone of an equivalent but opposed induced current from the secondary coil of the sonometer F, the degree of angle through which this coil has turned to produce silence being the degree of force of the extra-current. The induction sonometer† consists of two coils only, one of which is smaller and turns freely in the centre of the outside coil. The exterior coil being stationary, the centre coil turns upon an axle by means of a long (20 cm.) arm, or pointer, the point of which moves over a graduated arc or circle. Whenever the axis of the interior coil is perpendicular to the exterior coil no induction takes places, and we have a perfect zero; by turning the interior coil through any degree we have a current proportional to this angle, and in the direction in which it is turned. The value of the induction current for each sonometric degree was $\frac{1}{1000}$ of the primary current which passed through the wire under observation, the latter being variable at will from ·001 to ·250 ampere. There is also a reversing key (not shown in the diagram), in order to place the interruptor on the telephone circuit and close the battery current from H to A; the conditions then being the usual method of testing, except using the telephone in place of a galvanometer—a well-known method. The telephone, being exceedingly sensitive and rapid, is most suitable, whilst a galvanometer would be too slow, and its use, in fact, impossible for the researches I have been making. Numerous details have been necessarily omitted in this rough sketch of the instrument. Suffice it to say that it is perfectly adapted for the object sought, viz., the investigation and measurement of the self-induction which takes place in all wires.

By all previous methods the measurement of the resistance of a wire is taken when the current has been already some time in action, or, to use an expression of M. Gaugain, when the electricity has arrived at its "stable period." In telegraphy, electric lighting, and all applications using rapid electrical changes, another period has to be considered—viz., that during the rise and fall of the current; this he named "the variable period," and it is in this period that all the phenomena of induction take place. To observe the *stable* period, the current is continuously passed through the bridge (and consequently through the wire under observation), and the interruptor being placed in the telephone circuit allows us to find the exact resistance of the wire, free from all induction or change in the wire itself. To observe the *variable* period, the interruptor or rheotome (making at will from 10 to 100 contacts per second) is placed on the battery circuit, the telephone being joined as shown in the diagram. By means of a switch or reversing key these changes are made as rapidly and often as desired.

If there were no static or self-induction, no loss of time, or change of resistance, then the result from these two periods would be equal; but this is never the case, for we find that when the resistance is balanced to a perfect zero for the stable period, loud sounds are given out in the variable period, requiring a fresh adjustment or balancing of the resistance of the wire, as well as a compensating opposing induction current from the sonometer to balance the self-induction. If we balance the resistance or the extra currents alone there is no possible zero, but when both are compensated we find at once a perfect zero for the resistance of the wire, and for its extra currents.

Inductive Capacity of Metals —The results of the following experiments prove that the force and duration of the extra-currents depend upon the kind of metal employed as a conductor, its molecular condition, and the form given to the conductor, independent of its resistance or the electromotive force of the primary current. The increase of force by increased length is proportional to the length of wire less its additional resistance, but with wires of the same length increased cross section or diminished resistance does not produce a corresponding increase in the electromotive force of the extra currents. The time of charge and discharge of the wire is independent of the electromotive force of the extra currents; for, if we compare currents of equal electromotive force obtained from copper and iron, it will be found that the duration of these currents in wires of 1 mm. diameter will be seven times slower in iron than in copper, and a still greater difference will be found in larger wires. The longest or slowest charge and discharge take place in the purest soft iron, and have a constant ratio of increase with increased diameter of the wire; my experiments giving for wires of double the previous section, or for wires of four times less resistance, a mean increase of three times its previous duration. The electromotive force of the extra current in different metals will be seen in the following table, and in order that the values obtained from the sonometer may be clearly understood I have reduced the results to comparative values. The table of values was obtained on wires of similar length, having been repeated on a similar series of lengths ranging from 10 cm. to 5 metres. The instrument is sufficiently sensitive for pieces only 10 cm. in length, and the results from the short lengths were as pronounced and accurate as those for greater lengths. I may add that the instrument shows no effects or traces of static charge for the lengths mentioned.

TABLE I.—Wires 1 mm. in Diameter, 30 cm. in Length.

Soft Swedish iron	100	Copper	20
Soft puddled iron	78	Brass	13
Swedish iron, not softened	55	Zinc*	12
Soft cast steel	41	Lead	10
Nickel*	34	German silver	7
Hardened cast steel	28	Mercury*	2
Cobalt*	24	Carbon*	1

* Being unable to procure wires of these metals, they were tested in the form of strips, and compared with similar strips of copper. Mercury was in a glass tube 2 mm. in diameter; carbon tested in the form of electric light carbon from 3 mm. to 10 mm.

The above table is only true for wires of 1 mm. diameter, as the effect depends on the size of the wire in relation to the nature of the metal. In soft Swedish iron a diminution in the electromotive force of the extra-currents takes place with each increase in its section, and this has been partially foreseen by Maxwell,* who said: "The electromotive force arising from the induction of the current on itself is different in different parts of the section of the wire, being in general a function of the distance from the axis of the wire as well as time." From this I expected that the increase of electromotive force by an increased section would not increase directly as its sectional increase; but I was not prepared to find, as my experiments prove, that after a certain maximum diameter of wire has been reached a marked decrease in electromotive force takes place with each further sectional increase, and that this maximum is variable with each metal.

The diagram shows a rapid rise of force in soft iron from an extremely fine wire of 0·10 mm. section to a maximum at 1 mm., from which point there is a slow but continued decrease of force with each increase in the size of the wire, until at the comparatively great diameter of wire of 10 mm. the force is but a fraction more than in the extremely fine wire. Hard Swedish iron has a less initial force in the fine wire, and does not arrive at its maximum until the wire has 3 mm. diameter, being then nearly of the same force as soft iron of the same diameter; the fall from this point is somewhat similar, but less than soft iron until at 8 and 10 mm.; soft and hard iron have absolutely the same values. A curious change of values at different diameters will be seen in copper and brass. Copper, having nearly double the initial force in fine wires, arrives at its maximum at 4 mm.; but brass creeps slowly up, passing copper at 5 mm., arriving at its maximum at 6 mm., and finally, in the large section 10 mm., it has more force than copper, their positions being completely reversed. I have been unable to obtain wires of different diameters of other metals; but zinc rods of 10 mm. gave a still higher rate than brass, whilst in small diameters its force was less. For non-magnetic metals it is probable that the greater the specific resistance of the metal the greater will be the diameter of the wire before the fall commences. Carbon is remarkably free from self-induction, and although there is a rise of force in rods of 3 mm. to 10 mm., it is so small as to be hardly measurable. German silver rises with comparative rapidity, indicating that with wires of 20 mm. its force would equal that of copper. Carbon therefore seems peculiarly adapted as a resistance when used in the variable period of electric currents.

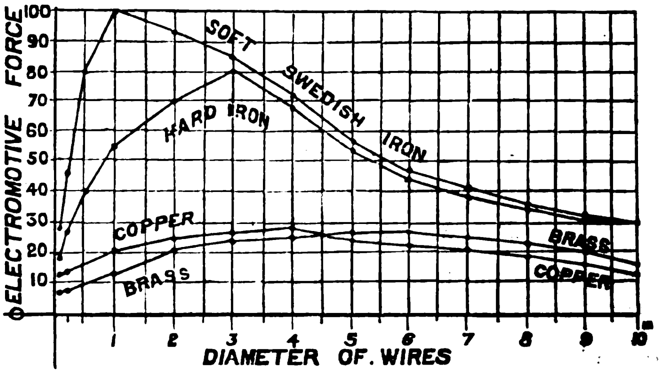

FIG. 2.

Influence of Parallel Currents.—The instrument being well adapted for showing the slightest change in the self-induction by the reaction of one portion of the current upon the other when in the same direction, as in a coil, or in the opposite direction, as in a parallel return wire, I made a series of experiments in order to observe the influence of different metallic conductors in this respect. Two silk-covered iron and copper wires of similar diameter and length (1 mm. diam., 2 metres in length) were each formed in a single loop of 66 cm. diameter. The extra currents from iron were, as usual, six times stronger than those from a similar loop of copper. On closing the loop by bringing the opposite sides in close proximity and thus making a parallel return wire (the current ascending on one side and descending the other), I found that the reaction of currents in opposite direction was very different with different metals, the results depending more upon the nature of the metal than upon the proximity of the wires. There was a reduction of the previous force of the extra currents in iron, when forming a parallel return wire, of 15 per cent., whilst the reduction in copper was 80 per cent. Thus the currents in copper are far more influenced by an external wire than those in iron; consequently a telephone line having its return wire in close proximity should invariably be of copper, as not only is its specific inductive capacity less, but this is again reduced by the return wire, so that its self-induction is far below that of iron.

In order to observe the influence of currents in the same direction, the same wires were formed into a close coil of twelve turns of 2 cm. diameter; and from the known effects of parallel currents in the same direction we should expect a greatly increased effect. It was so in the case of copper, but iron was far less under the influence of an external parallel current; the strength of current in iron when formed into a coil being 57 per cent. greater than that of a single wide loop, whilst in copper the increase was 404 per cent., or seven times the increase of iron; and although iron when in a single wide loop had six times the force of copper, the comparative strength was reversed when the wires were wound as a coil, the extra currents from the copper coil then having 14 per cent. greater strength than that from iron, and this difference could be rendered more evident by employing longer wires. Thus copper, as regards extra currents, is far more sensitive to the influence of external currents than iron, and the true self-induction from its own current can only be obtained by a straight wire, where the return wire is at such a distance that its influence is not appreciable.

Reaction of Contiguous Portions of the same Current.—It is well known that currents in separate portions of the same wire (as in a coil) react upon each other, and I felt convinced from the preceding experiment that self-induction is entirely due to similar electro-magnetic reactions between contiguous portions of the current in its own wire. Let us assume that an electric current consists of a bundle or an almost infinite number of parallel currents, the limit being a single line of consecutive molecules; then each line of current should by its electro-magnetic action react on each of the others similarly to wires conveying separate portions of the current, and the self-induction should be at its maximum when the lines are in the closest possible proximity, as in a conductor of circular section, and far less when separated, as in one of ribbon form, where the outlying portions are separated by a comparatively great distance. There would still remain, in the latter case, the reactions from the near portions on each other, and these should again be reduced by cutting the ribbon into a number of thin narrow strips, separated, except at their junction, to a sufficient distance to prevent any marked reaction.

My experiments prove that this assumption is an experimental fact, for we can reduce the self-induction of a current upon itself to a mere fraction

* "Electricity and Magnetism," Vol, II., p, 291.

Digitized by Google

of its previous force by simply separating as indicated the contiguous portions of a current from each other, the results proving that a comparatively small separation, such as is obtained by employing ribbon conductors in place of a wire of the same weight, reduces the self-induction 80 per cent. in iron and 35 per cent. in copper; and if we still divide the current by cutting the ribbon into several, say 16, strips (separating the strips at least 1 cm. from each other), then the combined but separated strips show a still greater reduction, being 94 per cent. in iron and 75 per cent. in copper. The following table shows the comparative reduction of self-induction by employing ribbons and parallel separated wires:—

TABLE II.

Flat strips compared with round wire 30 cm. in length.	Copper.	Iron.	Parallel wires 30 cm. in length.	Copper.	Iron.
Wire 1 mm. diameter...	20	100	Wire 1 mm. diameter.	20	100
Strips. 0·25mm. thick, 2 mm. wide....................	15	35	Single wire. 0·25 mm. diameter ...	16	48
Same, 5 mm wide	13	20	Two similar wires ...	12	30
„ 10 „ „	11	15	Four „ „ ...	9	18
„ 20 „ „	10	14	Eight „ „ ...	8	10
„ 40 „ „	9	13	Sixteen „ „ ...	7	6
Same strip rolled up in the form of wire......	17	15	Same, 16 wires bound close together	18	12

The resistance of a conductor, or even the nature of its metal, has less influence on its self-induction than the form given to that conductor, the 1 mm. wire in the above table having a less resistance than the strip of 2 mm. wide, and a greater than any of the wider strips; but through all these variations we notice a gradual fall from the wire to the widest strip or ribbon, with a marked return to its previous force when the ribbon is rolled up in the form of a wire. The reduction is greater in iron than copper, but its increase when rolled up is less than copper, thus agreeing with the previous observations on the difference of iron and copper to external reactions. A still greater reduction takes place when we separate a current by using parallel wires separated 2 cm. from each other, as shown in the table. We then have a similar reduction to that produced by cutting the strips into several separate conductors; and we again remark that when the wires are brought close together (forming a stranded wire) copper rises in a far greater proportion than iron, the 16 fine iron wires twisted together as a stranded wire having 88 per cent. less induction than a solid wire of similar weight; a remarkable fact being that whilst a solid iron wire has an inductive capacity 80 per cent. greater than a sold copper wire, this is completely reversed when each metal forms a stranded wire of the same weight as the solid, for iron then has 33 per cent. less self-induction than copper. It is not necessary to use extremely fine wires when we desire to reduce the inductive capacity of iron to that of copper, for I have formed wire rope of 16 strands of wire where each wire was 1 mm. in diameter, giving 75 per cent. less induction than a solid wire of the same resistance. I purchased an ordinary wire rope of 6 mm. diameter, having 6 strands of 6 wires, each 0·5 mm. diameter; this gave the best result yet obtained, for, on comparing 3 metres of it with a similar length of solid iron wire of the same resistance, the 36-stranded wire had only 5 per cent. of the amount of induction shown by the solid wire. Steel, in the form of ribbon or stranded wires, shows a similar effect to that of iron; and it is a remarkable fact that, whilst the extra currents from a steel or iron wire 4 mm. in diameter are extremely slow, and impossible to balance without reducing the time of the sonometer current (by the introduction of an iron core), the ribbon or stranded wire requires no such compensation, for its feeble extra current is exceedingly sharp, and can be balanced to a perfect zero, being acually quicker than that of a solid wire of copper of the same resistance. This fact I regard as one of greater importance for telegraph lines and lightning conductors.

A curious effect takes place if we employ mixed conductors, such as a compound wire of copper and iron. A fine coating of copper reduces the induction in a solid iron wire in a marked degree. This I found to be due to the difference of electromotive force of the extra currents in the two metals, for, by employing a fine copper wire parallel with an iron wire, and in contact at the ends, the extra current was reduced 60 per cent. The copper wire, having a lower electromotive force, probably acts as a shunt; but if the capacity of the iron has already been reduced, as in a sheet or stranded wires, then the addition of a single copper strand increases the force, as the electromotive force of the extra-currents of copper is above that of stranded iron. There has been for many years a discussion as to the merits of the round form as compared with the tape or ribbon form for lightning conductors. Those in favour of the former based their conclusions on experiments which gave a negative or no apparent difference between the two forms of conductors. Those in favour of ribbon conductors, as Sir W. Snow Harris, Prof. Guillemin, and many others, based their opinion upon marked differences found when using high charges of static electricity. The latter supposed that there was a difference between discharges of static electricity and voltaic currents of low tension, and that the advantage recognised by almost conclusive experiments was due in a great measure to conduction by surface.

In the year 1864, Prof. Guillemin and myself, as members of the Commission de Perfectionment of the French Telegraph Administration, were charged with the mission of testing the comparative merits of the lightning protectors then used upon their lines. Our method of experimenting consisted in joining an insulated conductor to a short fine iron wire connected directly with the earth return wire. A Leyden jar battery charged by a Rhumkorff coil was discharged through this conductor, burning or deflagrating the fine iron wire. This wire represented the telegraph instrument requiring protection, and by placing the lightning protector connected with the earth in advance of the fine iron wire we could observe the amount of protection afforded. This answered extremely well for feeble discharges, but with the full power of our battery the fine iron wire was invariably destroyed, even with the best lightning protectors which are universally used to this day. Noticing that we could not give absolute protection to the fine wire by lightning protectors, we tried the effect of joining the conductor direct to a separate earth wire in advance of the fine wire, and with powerful discharges the wire beyond the protection was invariably burnt, notwithstanding that we connected the conductor direct to earth by a copper stranded wire of 1 cm. diameter. Prof. Guillemin continued these experiments after my departure for Russia, and he found, by employing a thin sheet of copper as a conductor to earth in place of the copper stranded wire placed in advance of the fine iron wire, that the wire could be perfectly protected. The theory of this action was not understood at the time, and the experiment has not received the attention it deserved; but the mutual reactions of contiguous currents shown in this paper explain the phenomenon in the fullest degree, for we see that a sheet or ribbon conductor has far less self-induction than a wire or rod of the same material.

I am fully convinced from the results of my experiments that an enormous retardation or resistance is evident in all conductors at the first portion of the variable period, and that this is due to self-induction, the current thus arousing an antagonist in its own path sufficiently powerful, when the primary current has a high electromotive force, to deflagrate or separate the wire into its constituent separate molecules, as shown by Dr. Warren de la Rue. It is also evident from my experiments—which are easily repeated, with invariable results—that a flat conductor has far less self-induction than a solid of circular section during the variable period; and even with a constant current, as in the stable period, this form of conductor, as first shown by Prof. George Forbes, would, from its greater radiation, convey more current with less heating than a wire or rod of the same resistance. Lightning conductors are intended to convey a current of high intensity during an exceedingly short time, and should therefore be designed so as to convey this current with as little opposition from self-induction as possible; consequently I regard a solid rod of iron as the worst possible form for a lightning conductor. The conductor, if of copper, should be of ribbon form, say 1 mm. by 10 cm. wide, or, if of iron, of numerous stranded wires or a wide ribbon of similar conductivity to that of the copper.

Self-Induction of a Telegraph Line.—A telegraph line may be considered as a single loop; the earth taking the place of a return wire can only affect the self-induction by a diminution of its effects, as in the case of a parallel return wire. Mr. W. H. Preece has lately read a most valuable paper on "The Relative Merits of Iron and Copper Wire for Telegraph Lines,"* in which he shows, by comparative rates of speed with the same instrument, that on a copper and an iron line of 278 miles in length (between London and Newcastle), whose resistance and static capacity were rendered equal, there was an increase of speed in the copper line of 12·9 per cent. as compared with an iron wire. I have not been able to test the relative speeds obtainable by telegraph instruments on wires of different material. The results in every case would depend very much on the apparatus employed, but I have considered the question from a point of view independent of the instruments. There is a remarkable difference in the resistance of a wire during the stable and the variable period, the measurements taken in the stable period giving no real or approximate idea of what its resistance really is during the rise of the current in the wire.

A curious fact in relation to telegraphy is that all measurements are made during the period of a constant flow of current, whilst all instruments—particularly those requiring rapid changes in the current—work only during the rise and fall of the current, as in the variable period. Telegraph engineers, however, have not made the mistake of assuming that there is no difference in the resistance of a wire in these two periods, as it is well known that electro-magnets and coils have a far higher resistance during the rise and fall of a current, and coils simply augment the effect of a straight wire of a given length. The present method of testing by Wheatstone bridge has been adopted because we had no practical means of measuring the resistance in the variable period; and I do not believe that this can be accomplished except by a similar method to that which I have used, in which the resistance and self-induction are separately measured and balanced, and by the use of an exceedingly rapid and sensitive instrument of observation as the telephone, in place of the sluggish galvanometers, no matter of what construction. The speed of telegraph instrements is greatly influenced by the resistance of the wire. I said in 1883† that a great difference would be found in the resistance of an electrical conductor if measured during the variable instead of the stable period, and I have made numerous experiments with the view of ascertaining to what extent this difference would probably be felt on telegraph lines. I have already mentioned that the time or the duration of the extra currents increases rapidly with the section of the conductor; consequently, comparisons can only be made between wires of similar section for speed, or wires of similar resistance for differences in their variable period. In measuring the resistance of a wire during the two periods, I have found it best to avoid the use of resistance coils, the simplest method being to measure or balance a given length of wire in one period, and then observing how much lengthening or shortening of the wire would produce a similar zero in the second

* British Association, Aberdeen, September, 1885.

† Discussion on the paper of W. H. Preece on Electrical Conductors, *Proc. Inst. Civil Engineers*, Vol. LXXV., 1883.

Digitized by Google

period. Suppose that we commence by balancing the resistance during the variable period, and fix the sliding communications at the point at which we have obtained a perfect zero. We can now change to the stable period by means of the commutator; and as we no longer find a zero, but extremely loud sounds, we gradually lengthen the wire under observation until we have again a perfect zero. The amount of wire added to its previous length shows the difference in resistance between a conductor in which there are rapid electrical changes and that wherein the flow of current is constant.

Amongst numerous experiments I will cite a single example. I measured or balanced the resistance of an ordinary soft iron wire, 1 metre in length and 4 mm. diameter, during the variable period, and found that it required in the stable period exactly 2 metres 58 cm. to balance the previous resistance. Similar tests on a sample of best charcoal iron wire, as used on our telegraph lines, gave still more remarkable results, showing 225 per cent. difference between the two periods; for 1 metre of this wire had, during the rise and fall of the current, precisely the same resistance as 3 metres 25 cm. in the stable period. This shows that an iron telegraph wire has with rapid currents *more than three times* the resistance during its actual work than that supposed to be its true resistance. It was difficult on short lengths to find any change whatever in the resistance of copper or stranded iron wires in the two periods; the time of discharge being excessively rapid, I could only estimate the resistance by the electromotive force of the extra currents, or by forming the wires into coils (when a remarkably great difference is shown), and then estimating the proportional amount due to its own reaction; by this method I was enabled to detect 10 per cent. difference for a solid copper wire, and but 8 per cent. for the stranded rope of 36 iron wires. The difference in time of the duration of the extra currents between solid iron and copper and between solid iron and stranded iron is so great that we may consider a solid iron wire to belong, comparatively speaking, to the class of slow conductors, whilst copper and stranded iron would belong to the rapid.

I have shown a difference of resistance in the variable period between copper and iron of at least 200 per cent.—a difference which will be felt on instruments depending upon rapid changes, such as the telephone; and it is evident that the more rapid the contacts of a telegraph instrument the greater will be the difference between copper and iron. There is consequently a great electrical advantage in those instruments which require only a single current for each letter, as the economy of electrical impulses allows them to work at a comparatively high speed; the duration of the extra currents would be shorter than the length of their contacts, and consequently they would perceive very little, if any, difference between the two periods, or between iron and copper. If we use three or five currents for each letter, we must necessarily send them faster or closer together; and the difficulty increases in a rapid ratio with the speed of intermittent or reversed currents, until a point is reached (as I have shown in the case of best charcoal iron) where, whilst nominally working through 500 miles, we are practically working through an equivalent resistance of at least 1,500 miles, and this without taking into account the static charge, which would, in addition, from its comparatively extreme slowness of charge and discharge, cause the apparent resistance of the wire in the variable period to be much greater than I have mentioned. In Mr. Preece's experiments he finds a difference of speed of 12·9 per cent. between iron and copper, which is far less than the difference of resistance during the variable period which I have obtained; and this may be explained by assuming that the speed of the reversed currents which he employed was only near the border land of extra currents. I am convinced that if Mr. Preece could have increased the speed of the instruments he would have found a far greater difference between iron and copper; and if I regard the results of a solid iron wire alone, I should consider iron as unsuitable for telegraph instruments requiring extremely rapid currents. Copper would reign supreme if it were not for the fact, which I have discovered, that stranded iron wires have even a greater rapidity of action than copper.

Physical Changes in the Conductor.—Self-induction not only depends on the nature and form of its conductor, but also on the physical state of the metal, as already shown in the case of soft and hard iron. I felt convinced that the higher force in iron was due to its magnetic capacity, and to prove this I tried the effect of heating the wire to a bright red heat, or 1,000 deg. C. It is well known that iron loses its magnetic properties at bright red heat, and I found that its self-induction then fell to less than that of copper. This would have been conclusive had it not been for the fact that a different result takes place when the capacity of the iron for self-induction has already been reduced, as in the case of thin flat sheets of iron; in this case there is no disappearance or further decrease of induction except that due to the extra resistance caused by the increased temperature of the strip. Now, as the strip was highly magnetic when cold, and lost this property at red heat, there should have been some change in its self-induction if this were due to the magnetic nature of the iron alone. This requires further researches before a probable explanation can be given.

Iron is peculiarly sensitive to all physical changes. Mechanical strain of all kinds hardens the wire, and its influence on its self-induction can at once be detected. An iron wire under a moderate longitudinal strain loses 40 per cent., and its capacity is then less than unstrained cast steel. Iron well annealed has much less resistance than the same iron when hard drawn, and soft iron is generally employed for telegraph lines; but during the variable period a curious reversal takes place, as then soft iron has a higher resistance than hard iron. This apparent anomaly is easily explained if we compare the far higher self-induction of soft iron. Work is done at the expense of electrical energy, and the apparent higher resistance is due to the greater electro-magnetic action in soft iron. An iron wire shows traces of remaining circular magnetism after the passage of a continuous current, reducing the following extra currents 10 per cent.

Magnetising the wire, or subjecting it to mechanical vibrations, when used separately, produces no apparent change in its inductive capacity, but a remarkable change takes place if either of these is used in conjunction with a constant current. Let us pass a constant current and heat the wire to red heat, allowing it to cool with the current on; or, in place of heat, magnetise the wire; or, in place of magnetism, give the wire mechanical vibrations: the result of either of these being a strong internal circular magnetism, due, I believe, to the loosening of the magnetic molecules, allowing them to rotate with greater freedom under the influence of heat, mechanical vibrations, or magnetism. A wire thus treated has no longer its previous self-induction, which has fallen 60 per cent.; and as the circular magnetism becomes fixed when the vibrations cease, this molecular structure remains a constant as long as we employ intermittent currents in the same direction, but the structure disappears the instant a reverse current is sent; and this explains why we have more than double the amount of self-induction from reverse currents, as each reversal destroys any remaining magnetism due to the previous passage of the current. If we compare the electromotive force of self-induction on a given length of wire with the secondary currents generated in a second but independent circuit, we find that the self-induction is the most powerful, the secondary currents generated in a close independent copper wire being 20 per cent. less than its own wire. There is no difference between the self-induction of a current and the secondary currents; they are, in fact, as proved by Faraday, part of the same phenomenon. The self-induction is evidently due to the electro-magnetic reactions of the primacy current, and as magnetism permeates space, the separation of the wire only serves to insulate the primary, but does not affect its magnetic influence; and, as I have shown in the reactions of contiguous portions of the same current, so the magnetic reactions perpendicular to the axis of the current continue through the wire to all surrounding wires; and if we call the currents in the independent wire secondary, they are still secondary whilst enclosed in the wire of the primary; and as the reaction will ever be the strongest in the axis of the current, so will these currents be necessarily stronger than those induced in independent wires. For this reason we should be able to obtain extra currents of far higher electromotive force than would be possible from a secondary wire of the same length. It was my intention, on the reading of this paper, to demonstrate by practical experiments some remarkable properties of extra currents of high electromotive force; but I find that the subject and apparatus employed require a longer description than the limits of this paper allow. I must also leave aside for the present my experiments upon coils of different forms with cores of different metals. These, as well as other results obtained, indicate that there is a large field of useful research in many directions, each, however, requiring special studies according to the object we may have in view. The record of numerous experiments, of which this paper is only an abstract, shows that the nature of the metal as well as its physical condition has an important influence upon the self-induction of an electric current, and by a study of the reactions produced by the contiguous portions of a current, and by application of the results, we may, as in the case of iron, transform an extremely slow conductor into one of the greatest rapidity; I therefore hope not only that these researches may be of interest from a scientific point of view, but that the results obtained may be of practical utility in some of the numerous applications of electricity.

COMPANIES' MEETINGS & REPORTS.

The Cuba Submarine Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the shareholders of this Company was held at the Company's offices, 61, Old Broad-street, on Wednesday, 3rd February, under the presidency of Mr. Joaquin de Mancha.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, the report enters so fully into all our doings during the last six months that I think it will require but few words from me on this occasion. You will see by the accounts that, after providing for the payment of the 1881 cable—the proportion that is due—and all other expenses, we have the sum of £8,641 for division. I think, taking into consideration the depression of trade all over the world, we must consider that the account is very satisfactory. Unfortunately we have suffered from that depression, for our business has somewhat declined. We have had about 500 fewer telegrams, as compared with the corresponding six months of last year, decreasing our income by about £1,000. Unfortunately last year, as we all know, the price of sugar was very much depressed, and as all the West Indies depend so much for their prosperity on that article, business men were therefore not so free in their communications, as the article they dealt in was at so low a price. But we hope that this year the crop will be very much better, and that our business will increase in consequence. There is one remark that I wish to make to you in reference to Paragraph 6 of the report, which says:—"The British Goverment having invited tenders for the laying and maintaining of a cable between Halifax (Nova Scotia), Bermuda, and Jamaica, with an Imperial subsidy, the Board has fully represented to the Government that the scheme, if carried out, would prejudicially affect the interests of this Company." When we first saw this advertisement we thought it desirable to communicate with all our friends connected with our line. After many consultations; and, in fact, having drawn out a scheme so that we might, if it was thought desirable, make an offer for laying this cable, we found that some of our colleagues would not enter

Digitized by Google

into the matter. At one time it was thought that if they had all contributed towards the floating of a company, so as to be able to make an offer to the Government to lay down this cable, we might have to come before you to ask you as members of the Cuba Submarine Telegraph Company to take shares in this new company, but after due consideration we thought it was advisable not to offer at all. The difficulties connected with it are very great. From the report that the "Challenger" made to the Government it was found that the depth of the ocean was very great indeed—that in some cases the bottom was very rocky, and that we should have had in some parts to go down to a depth of four miles, so that in case of any accident it would have been almost impossible to get the cable up again. We thought, therefore, it would be advisable to have nothing to do with it. But we wrote to the Government to this effect, that if they should give a subsidy to some other company it might seriously injure us. The Government reply was as follows:—"Sir, with reference to the letter from this department of the 9th inst., I am directed by Secretary, Col. Stanley, to inform you that the Lords Commissioners of the Treasury have considered your representations respecting the proposed construction of a telegraph cable between Halifax, Bermuda, and Jamaica, and that Her Majesty's Government cannot depart from the decision which was arrived at on the ground of public policy to subsidise a cable between those points. Of course any tender in respect to the proposed new line of cable which your company may desire to make will be duly considered; together with other tenders in response to the advertisement, if sent by the 15th inst., as therein required." Well, gentlemen, after having received that reply we took no further action in the matter, except in endeavouring to ascertain whether other companies had offered for the laying down of this new cable. We have heard that there were two or three construction companies that made tenders, but we have not been able to ascertain upon what conditions, or whether the Government have accepted the tenders or not. Perhaps you would like to know the latest news we have on the subject. I wrote to the Government again, asking if they could inform us whether any offer had been accepted, or whether they had made any modification in their plans. To that we had no reply. Therefore, I expect that with the change of Administration and one thing or another they have not given their minds to it. We are consequently just as we were. We hope that the cable will not be laid. It would certainly prejudice us. But if it is laid we must do the best we can to make some arrangements by which this Company may not be seriously prejudiced. I think, gentlemen, that is all I have to say, except that, so far as our investments are concerned, you will see that following the desire of some of our members at one of our meetings we are reducing the amount that we have in some of the banks, so that it should not exceed £5,000 or so. But in these times of cheap money we have already had notices from some of the banks that were paying 5 per cent. that they will not be able to give us more than 4½ per cent. Therefore, for the present, we think it advisable not to move any farther. All the banks where our money is deposited are most reliable, and some of them, I think, compare favourably with any banks in the world, and we do not consider that it would be judicious to change from one bank to another, but to leave things as they are, so as to ensure as long as we can our gaining 5 per cent., which in these times is very difficult to do. With these observations, I will now move "That the report and accounts now submitted be received and adopted," and if any gentleman wishes to have any further explanation that I can give I shall be most happy to afford it.

Mr. A. F. Low: I beg to second that.

Mr. Greag congratulated the Board on having been able to keep the Company in so good a state as was revealed by the accounts. He threw out as a suggestion that it might be in the interests of the Company that the Board should devise some means whereby both preference and ordinary shareholders might sail in the same boat.

Mr. Goddard imagined that the securities in which their money was invested did not produce altogether 5 per cent., and he suggested whether the Directors should not be empowered by the shareholders to buy up the preference shares as they came into the market. They might thus effect some saving in the way of interest, and by some process gradually lead to the extinction of the preference shares.

Mr. Griffith congratulated the Directors on their past success, which he hoped in these perilous times would not desert them. He thought the Conservative Government were placing themselves in a wrong position when they came forward merely as the champions of the military, and entirely ignored the commercial interests involved in the question of laying the proposed cable. There could be no doubt that the Government had done wisely in deciding to lay an additional line to the West Coast of Africa, because there was a larger opening for trade there. The amount of time gained over the present system by laying that additional line would be inappreciable. Besides, in the event of war the cable would very likely be broken, and therefore unavailable. He was very glad to hear that the Board had determined to take no part in it. The depth of the ocean was so great in parts, that it would be almost impossible to grapple the cable and bring it to the surface again should it at any time come by an accident. He hoped Mr. Gladstone and his colleagues, who had greater respect for the interests of trade than the Conservatives, would not consider it necessary to sacrifice the shareholders for military reasons which were without foundation.

The Chairman said that the question of buying up the preference shares had engaged the attention of the Board, but it had been considered inexpedient to do so. The manager at Cuba had successfully repaired three or four defects in their cable at a very small outlay, without putting the Company to the expense of hiring and sending a steamer from England. The full expenses of that to the 31st of December had been about £500, and there would only be a few pounds more. He expressed the hope that under the Liberal Ministry it would not be considered necessary to proceed with the proposed new line between Halifax, Bermuda, and Jamaica.

The resolution was then carried unanimously.

The Chairman next proposed "that a dividend at the rate of 10 per cent. per annum free of income-tax on the preference shares, and 7 per cent. per annum free of income-tax on the ordinary shares, payable on and after to-morrow, be now declared."

Mr. Low seconded the resolution, which was agreed to.

On the motion of Mr. Goddard, a cordial vote of thanks was passed to the Chairman and Directors for their able conduct of the Company's business during the past six months.

The Chairman briefly replied, and the proceedings terminated.

The Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held on Monday at the Cannon street Hotel, Mr. Hugh Watt, M.P., in the chair, for the purpose of confirming the resolutions passed at a meeting of the Company held on the 15th ult.

Mr. John Wright (the Secretary), read the notice convening the meeting.

The Chairman said: Gentlemen, I do not know whether it is necessary for me on this occasion to repeat the arguments which I used when these resolutions were first placed before you as to the reasons which have induced the Board to arrive at the conclusion as to the desirability of reducing the amount—well, virtually reducing the amount—to the debit of patents account—that is, by reducing the capital of the Company to 5s. per share. I think, at least I hope, I made it clear to the shareholders on the last occasion that we considered ourselves, in view of existing circumstances, overweighted by an amount of capital which, as far as the present Board are concerned, never existed. In my humble opinion no patents at the present moment are equal to those in the possession of this Company, but in spite of that fact I do not think that it would be to the interests of the shareholders of this Company to reduce their capital to 5s. a share, which would reduce the patent account by something like £50,000. One reason which induced us to arrive at this conclusion was the existing state of the electrical market. We have not gone in connection with this company upon anything of an illusory character, and I hope we have viewed the position from a purely commercial point of view, and the Company has been conducted as far as we were able as a private enterprise. The result has been, in the opinion of the Directors, satisfactory so far, and we believe with the capital reduced as we propose, that we shall be able greatly to improve our position, and be able year after to present to the shareholders of this Company a more satisfactory condition of things than we have been able to do in preceding years. Another reason has been that in the opinion of our solicitors and counsel it would have been impossible for us for the past year to have declared a dividend. You were good enough at the end of last year to suggest in opposition to my recommendation the advisability of retaining the sum we proposed to pay in dividend, as working capital. On this occasion, I do not think we should ask the shareholders to show an equal degree of magnanimity—in fact, I think that now we ought to pay something. It is quite true that the present Board have not been in office since the floating of the original Electric Lighting Power Company, but the shareholders who, like myself, invested at a high premium, naturally want some return for their money, after some few years delay. I shall now propose, without further comment, the following resolution, and shall be glad to answer any questions put by any shareholders. I beg to propose that the following resolution be confirmed:—"That the capital of the Company be reduced by £62,500 by cancelling paid-up capital, unrepresented by available assets (being patents over-estimated in value) to the extent of 5s. per share upon each of the 250,000 shares which have been issued and are now outstanding."

The motion was seconded by Mr. Brown, and carried *nem. con.*

The Chairman then proposed for confirmation: "That the capital be further reduced by £62,500, by reducing the nominal amount of the remaining 250,000 shares of the Company's capital from 10s. to 5s. each, thereby leaving the nominal capital of the Company, £125,000, divided into 500,000 shares of 5s. each.

Mr. Lewis Swaby seconded the motion, which was carried unanimously.

The Chairman, referring to the financial position of the Company, said that the Board had deemed it advisable to pass the sum of £3,605. 5s. to a general reserve account, having been induced to do that from the fact that the late Board had left, among other legacies, a probable bad debt of £4,700. After allowing for the before-mentioned sum the balance remaining at the credit of the profit and loss account as at December 31st, 1885, was £5,285; and, seeing that the shareholders last year did not see fit to adopt the recommendation of the Board for the payment of a dividend, he was now willing to accept any suggestion for the distribution of a dividend.

Mr. Griffiths proposed the payment of a dividend of 7½ per cent. for the last year.

Mr. J. Barratt seconded the motion, which was carried unanimously.

The Chairman said the Directors would willingly carry out the wish of the meeting, and they would convene a general meeting within the next two weeks.

A vote of thanks was then passed to the Chairman for his services in connection with the resuscitation of the Company, and for his able administration of its affairs.

The Chairman, in acknowledging the compliment, said that he had received from influential sources promises of support of the Bill relating to amendments upon the existing Electric Lighting Acts, of which he gave notice on Thursday last, and he had reason to believe the Government would view his proposal very favourably.

The proceedings then terminated.

Anglo American Brush Electric Light Corporation (Limited).

Report of the Directors to be submitted to the Shareholders at the fifth ordinary general meeting of the Corporation, at the Cannon-street Hotel, on Wednesday, the 10th inst., at 3 o'clock :—

The general prospects of the electric lighting industry have continued to improve, and although the advance has not been so great as was hoped for, the business and profits of the Corporation have sufficiently increased to justify, in the opinion of the Board, the distribution of a dividend. The range of the business of the Corporation has, during the past year, been largely extended. As a result of the absorption of the Great Western and Brush Midland Companies, reported on last year, important centres have been secured in South Wales and the West of England, and there is no reason to doubt that when the present legislative obstacles to central station lighting have been removed, the Corporation will benefit by the connections which have been established. An important station has also been acquired at Manchester, while a branch office has been opened at Edinburgh. The Continental work of the Corporation has again been of a very encouraging character, and the agency for the German Empire, organised about eighteen months back, especially promises further good results, the Corporation having lately entered into an arrangement for the establishment of a central lighting station in an important part of Berlin. In view of the magnitude and increasing importance of the foreign interests and relations of the Corporation, the Board have recognised the necessity of having a representative abroad, and they have appointed Mr. Frank Wynne, who for the last two years held the post of General Manager in England, to superintend the Continental work of the Corporation. The Corporation are able to show a satisfactory record of practical work done during the year. In addition to the share of Government contracts for the supply of electric lighting apparatus which the Corporation continue to receive, several profitable and interesting installations of the electric light have been carried out in docks, railway stations, collieries, factories, and private houses; also, as a somewhat new departure, a very successful installation has been completed upon the Duke of Bedford's yacht, "Northumbria," and upon others of a similar class. The International Inventions Exhibition afforded the Corporation a favourable opportunity of bringing to the notice of the public the merits of their numerous patents, the commercial and scientific value of which was recognised by the award of a gold medal. After referring to the fact that the Corporation are free from litigation, and their intention to enforce the legal recognition of their patent rights, the Directors refer with confidence to the early amendment of the Electric Lighting Act, and the introduction of the draft Bill prepared last year by the Electric Lighting Committee, which has been taken as the basis of a measure to be shortly submitted to the House of Lords by Lord Rayleigh.

The report continues: It will be seen from the balance-sheet that the called-up capital stands at £190,174. This is a diminution upon the figure at which capital stood last year of £795, due to the maximum number of shares to be issued to the members of the Great Western and Brush Midland Companies having been reduced by 159 shares in consequence of arrangements, advantageous to the Corporation, made with some of the shareholders of the Midland Company, by which they relinquished their claim to these shares in consideration of the liquidators accepting the difference only between the amounts of the call due by them and the value of the shares in the Corporation to which they would have become entitled upon paying the call in full. The total amount owing by the Corporation to creditors is £6,233. 17s. 2d., as against £3,726. 6s. 4d. in 1884, while the good debts due to the Corporation, together with cash at bankers, amount to £39,563. 1s. 2d., as against £30,102. 0s. 10d. last year, a comparison which will serve to indicate to some extent the improvement which has been effected in the financial position of the Corporation during the year. The patents and goodwill account has been increased by £12,536. 6s. 4d., about £11,000 of which represents the consideration paid in shares of the Corporation to the Great Western and Brush Midland Companies for the surrender of their licenses and the goodwill of their business. The reason for the amount of this consideration being larger than the estimate contained in the last annual report is that some of the other assets transferred by these companies to the Corporation have, in consequence of the reduced valuation of the plant and stores of the Corporation, been merged into the books at figures much below the original and otherwise perfectly justifiable estimates. The property account shows an increase upon last year's figure of £11,786. 8s. 10d., which is mainly due to the acquisition of the freehold and leasehold land and buildings and plant of the Great Western and Brush Midland Companies at Cardiff, Bristol, Cleethorpes, and other places, and to the purchase of the central generating station at Manchester, already referred to. The stock account, which stands at £69,626. 13s. 7d., shows no material alteration in the aggregate value of the stock on hand (taken at the valuation mentioned in the last annual report), stores, and goods in course of manufacture. The amount of £1,699. 11s. 6d. standing to the credit of assets realisation account represents the residue of the assets of the Great Western and Brush Midland Companies still to to be transferred to the Corporation by the liquidators. Should the assets still in the hands of the latter not realise this amount the deficiency will be added to the cost of the goodwill, &c., of these companies, in accordance with the principle laid down in the last annual report. The profit and loss account shows a gross profit of £20,935. 9s. 3d. after providing for bad and doubtful debts, and including the £500 received from the Anglo-Spanish Company mentioned in paragraph 11. After deducting all standing charges and expenses there remains a balance to credit of profit and loss account, including the balance of £1,627. 15s. 4d. brought forward from last year of £6,728. 6s. 8d. The standing charges, it will be noted, show an increase in the aggregate of £1,140. 17s. 2d. This is due partly to the higher premiums now generally demanded by fire insurance companies, to additional advertising, travelling, and to such other expenses as are directly attributable to the larger volume of business transacted by the Corporation during the year, and to the steps taken in furtherance of increased future developments. The Board recommend that £2,000 be applied to the reduction of properties and plant account, that £3,803. 9s. 7d. be applied to the payment of a dividend at the rate of 2 per cent. per annum on the whole share capital of the Corporation, and that the balance of £924. 17s. 1d. be carried forward to next account.

The report, in conclusion, says:—The Directors consider that there is good ground for encouragement in the prospects of business during the current year. The Corporation have already secured important contracts for lighting portions of the various Exhibitions to be held during the summer, and there is reason to hope that the negotiations which have been carried on during the past two years with the Corporation of the City of London for lighting an extended area are now approaching a satisfactory termination. The Board much regret to announce the loss to the Corporation of the services of two of the original Directors. Mr. Ladd, whose critical illness was referred to at the last meeting of the shareholders, died soon after, and later in the year Mr. Courtenay resigned his seat at the Board, owing to pressure of other engagements. The vacancies on the Board thus caused have been filled by the appointment of Lord Sudeley and Major-General Webber, R.E., C.B., and the shareholders will learn with satisfaction that the latter has been induced to accept the position of Managing Director. The Directors who retire this year are the Chairman, Lord Thurlow; the Vice-Chairman, Mr. Sellon; and Colonel Steuart, who, being eligible, offer themselves for re-election. Messrs. Cooper Brothers and Co., the auditors, also retire, and offer themselves for re-election. It is proposed that the dividend be payable on and after the 1st March.

THE KINETIC ENGINEERING COMPANY.—This company have opened a branch depot and show room at 117, Queen Victoria-street, E.C.

NOTES.

COREA.—The first telegraph line in Corea was opened on the 27th September.

SOCIETE BELGE D'ELECTRICIANS.—This society, which is now in its third year of existence, numbers 253 members.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—Gross earnings of this company for the month ending January 31st, 1886, £3,200.

THE POSTMASTER-GENERAL.—Lord Wolverton, the new Postmaster-General, has appointed Mr. F. A. R. Langton to be his private secretary.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 5th inst. amounted to £2,814.

PERSONAL.—Major R. L. Hippisley, Royal Engineers, has been appointed Instructor of Telegraphy in the School of Military Engineering, Chatham.

NEW ZEALAND.—Advices from New Zealand state that the cable steamer "Sherard Osborn" had left Wellington for Cook's Straits to repair the cable.

AN EXHIBITION OF LIGHTING APPARATUS.—It is stated that the Belgian Engineers' Association is preparing to hold next month an exhibition of all the various means of illumination hitherto used.

A CHANCE FOR ELECTRIC LIGHTING COMPANIES.—At the last meeting of the Northfleet Local Board the clerk was directed to issue advertisements inviting tenders for lighting the public streets of the district.

ELECTRIC RAILWAY.—Denver, U.S.A., is experimenting with an electric railway. Rails have been laid over a distance of about three miles. Prof. Short, of the Denver University, is the inventor and superintendent.

FIRE ALARMS.—The extensive premises of Messrs. Whiteley in Queen's-road and Westbourne-grove have been connected by means of the Exchange Telegraph Company's fire alarm with the fire station, Hermitage-street.

ATLANTIC CABLES.—Communication between Europe and America might have been entirely interrupted for many hours on the 29th ult. had it not been for the Mackay-Bennett direct New York cable *viâ* Coney Island.

APPOINTMENT.—We understand that Mr. William Fowler, Postal Telegraph Service, Aberdeen, has been appointed inspecting telegraphist for the north of Scotland. Mr. Fowler has been in the Aberdeen office for 15 years.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 5th inst. were £2,214, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—Subject to the audit, the directors of this company propose a dividend of 15 per cent. (£1. 16s. per share), in addition to the interim dividend of 5 per cent. already paid, making 20 per cent. for the year 1885.

NEW COMPANY.—It is reported that a company has been registered under the title of the Welsbach Incandescent Light Company (Limited), for the purpose of acquiring "the benefit of an invention of Dr. Carl Auer von Welsbach for incandescent lights." Capital £30,000, in £1 shares.

APROPOS OF THE ELECTRIC BOY.—*Apropos* of the electric boy, those of our readers who are interested in marvels should look up the account of the *Reduvius Serratus*, or West Indian Wheel-bug, in our issue of May 29th, 1880, and the description of the electric cow in our issue of July 10th, 1880.

ELECTRIC STORM SIGNALS.—If it be required to show storm signals during the night-time at the signal service station in Boston, U.S.A., the lanterns are lighted by electric lights, which make them remarkably brilliant. This is the only station in the country at which electric lights are used for the signals.

THE SENSOPHONE.—A modification of the sounder telegraphic instrument has been introduced in the United States. It is called the sensophone, and delivers signals by a series of light pricks, the finger being placed upon a button on the instrument. It is said to have found favour with operators.

THE ELECTRIC LIGHT FOR WARSHIPS.—The new French ironclad "Le Courbet" is to receive an installation of 350 incandescent lamps for the interior of the vessel, and 12 lights of 30 candle-power, and 2 powerful arcs for deck use. The work has been entrusted to Messrs. Sautter, Lemonnier, and Co.

THE ELECTRIC LIGHT FOR MILLS.—MM. Jamin and Leroux, of Mans, have ordered 100 incandescent lamps of Messrs. Sautter, Lemonnier, and Co. These, we understand, are for an experimental installation; if found satisfactory, the mill belonging to the firm will be lighted throughout by electricity.

THE ZIPERNOWSKY-DERI SYSTEM IN ROME.—An installation, including the use of 12,000 lamps, varying from 8 to 10 candle-power, is to be put down in Rome. The system employed is to be the Zipernowsky-Deri, and Messrs. Ganz and Co. have charge of the work. 1,500 lamps are to be in position by next May.

AN INTERESTING PAMPHLET.—We have been favoured with an exhaustive pamphlet by Mr. F. J. Sprague on the "Application of Electricity to Propulsion on Elevated Railroads." Pressure on our columns has prevented us hitherto from presenting this interesting paper to our readers. We shall, however, publish it at the first opportunity.

QUICK WORK.—One of the leading firms of arbitrage brokers in New York sent a message on the 28th ultimo from the Stock Exchange office of the Mackay-Bennett Cable Company to London. The business referred to in the message was transacted, and the answer received in New York in the space of *six minutes*, the quickest time on record.

THE TELEPHONE IN BELGIUM.—On the 24th inst. a concession for the establishment and working of a telephone system in the town of Termonde and its vicinity will be let by public contract at the Brussels Bourse. On the 3rd proximo a similar concession will be let for the town of Malines. The caution money in each case is fixed at £400.

LOCAL SOUNDERS IN AMERICA.—Our American namesake states that there are in daily use on the Morse telegraph lines of the United States not less than 30,000 local sounders. The total consumption of copper in the local batteries amounts to about 750,000lb. per annum, representing a sum of £6,300. Of zinc, 100,000lb. is used, equivalent to a value of £1,200. The total value is probably over £10,000 per annum.

SHREWSBURY.—At the last meeting of the Shrewsbury Town Council the town clerk stated that a communication had been received from the Post Office authorities to the effect that they should require £12 a year for supplying the electric clock, under a lease for five years. The wires would be supplied by the post office authorities, but the receiving appliances would have to be supplied by the Town Council. The consideration of the question was adjourned.

Digitized by Google

SKATING BY THE ELECTRIC LIGHT.—During the skating season the large loch at Morriston Farm, Cambuslang, near Glasgow, was brilliantly lighted by means of three Crompton "D. D." arc lamps of 3,000 candle-power each, supplied by current from a Crompton-Bürgin machine. The loch was crowded each evening, and the scene is stated to have been picturesque in the extreme. The lighting was carried out by Messrs. Henry Bennett and Co., of Glasgow.

CITY AND GUILDS OF LONDON INSTITUTE.—As will be seen on reference to our advertisement columns, a course of 12 lectures, for engineering students and others, "On the Differential and Integral Calculus," will be given by Prof. Henrici, F.R.S., on Wednesdays, at 5 p.m., commencing on the 3rd prox. A course of six lectures, "On Some of the Industrial Applications of Electricity," will be given by Prof. Ayrton, F.R.S., on Friday, at 5 p.m., commencing on the 12th prox.

SWAN LAMPS IN GERMANY.—It is said that in the patent suit Swan *v.* Edison, the Swan Company has withdrawn its appeal before the Court at Leipzig, after the report of the referee, Justizrath Hambrock, had been communicated to the Court and the parties, so that the recognition of the Imperial Patent Office, which had been claimed by Edison for nearly two years, is now legal. The Swan Company is understood to declare that it will continue the pending civil proceedings in the Berlin Court.

WHERE IS IT?—Our contemporary the *Metropolitan* says that at a special meeting of the Blackwall Town Council it was decided not to proceed with the proposed Improvement Bill, by which, it may be remembered, the Corporation sought to create a reserve fund in connection with their gas undertaking, and to revise and extend their electric lighting powers. We should like to hear something more of the proceedings of this council. We were not aware that Blackwall had attained to the dignity of a town.

THE WAVERLEY STATION INSTALLATION.—Owing to a slight accident to the dynamo machine, the electric lights at the Waverley Station, Edinburgh, went out on the night of the 5th inst., and the old gas lamps had to be called into requisition. Further advices state that the accident to the dynamo turns out to be of a more serious nature than was at first supposed. Part of the machinery has had to be forwarded to London for repair, and it is now believed that the lighting cannot be restored in less than a week.

A CURIOUS STORM.—Not long ago a fearful dust storm passed over Redhill, in South Australia. A thunderstorm also threatened, but little rain fell, although but a few miles distant, in a north-easterly direction, a large quantity of rain filled up dams and replenished tanks. Thunder and ligntning were severe at the time. The lightning struck the Hummock Ranges, setting fire to the grass, destroying over 300 acres of good feed. Several hundred sheep which were grazing on the land at the time of the fire narrowly escaped being destroyed.

AN INTERESTING INSTALLATION.—There is an interesting installation at Greenock. It consists of two 100-light dynamos, driven by a turbine, which is in turn driven by the town water supply on its passage to the filters. There are twenty 20 candle-power Swan lamps in the streets, fitted in the ordinary gas lanterns, and 90 Swan lamps, of the same power, fitted in a neighbouring sugar refinery. The installation has now been working for nearly twelve months, and we are informed that all the lamps have exceeded the span of life generally accorded to them.

ZINC.—L. l'Hote, in *Comptes Rendus*, says: As to the inquiry if zinc free from any foreign metals decomposes water either on boiling or in presence of dilute sulphuric acid, experiment proves that such is not the case. Pure zinc heated with distilled water in a flask, so arranged as to receive the gases over mercury, gives off no hydrogen on prolonged boiling. Nor is it attacked by dilute sulphuric acid. The presence of iron in proportions of from 3 to 5 in 100,000 enables it to decompose water. Traces of arsenic and antimony have the same effect.

THE EDINBURGH EXHIBITION.—We are informed that Messrs. Andrews and Co. have been allotted the lighting of a large portion of the International Exhibition to be held in Edinburgh in the coming season. The space thus allotted will be lighted with thirty-four Andrews arc lamps, supplied with current from two dynamo machines. One powerful Andrews arc lamp will also be erected on a mast 80ft. high in the courtyard of Old Edinboro. The other lights will be distributed throughout the machinery and motion departments of the exhibition.

GAS AND ELECTRICITY.—It was stated on the 10th inst., at the meeting of the Anglo-American Brush Electric Light Company that a Bill would shortly be introduced into the House of Lords to place electric lighting on the same footing as gas, and to effect that two clauses of the Act of 1882 would have to be repealed. That would stimulate an industry to such an extent that it alone would prove most efficient as relief works for the unemployed. It was calculated that work would be provided in London alone for over three years for more than 10,000 men at an expenditure of over £6,000,000.

GAINSBOROUGH.—The installation at Marshall, Sons, and Co.'s, of Gainsborough, is a very complete one. Their machine is capable of driving 40 lamps of 15 amperes or 60 lamps of 10 amperes, in 12 parallels of five each. Messrs. Marshall have provided for four such machines, so that it will be possible for them to put up 240 arc lamps from four dynamos, with an E.M.F. considerably below 300 volts. On the American system of running a number of lamps in series, this might be accomplished by four or five large machines, but the E.M.F. would have been fatal to anyone accidentally touching the wires.

PROPOSED TELEPHONIC EXCHANGE IN DUNFERMLINE.—A meeting was recently held in St. Margaret's Lecture Hall, Dunfermline, for the purpose of considering the propriety of establishing a telephonic exchange for Dunfermline, to be connected with Glasgow, Dundee, Stirling, and other towns. Mr. A. R. Bennett, the general manager of the National Telephone Company, was present, and explained the nature of the proposal, and the success which had attended the telephonic system in other towns. The scheme was favourably received, and it was left with Mr. Bennett to arrange for securing the necessary number of subscribers.

ANOTHER BOY BATTERY.—An American contemporary states that Frank Burnett, aged 15, residing with his widowed mother at Youngstown, O., is said to have developed powers indicating that he is an animated electric battery. He is slightly built, and on his approach chairs and tables dance and heavy articles totter that his natural strength could not move. The lad is unable to explain his unnatural power, and has always enjoyed good health. The tests made thus far show the lad to be able to do more than he has claimed. It is probable that medical experts will be called in to ascertain whether this phenominal youth is a cell or a sell.

THE ELECTRIC LIGHT IN LUCERNE.—Messrs. Ganz and Co., of Budapest, are engaged in installing the central station at

Digitized by Google

Lucerne on the Zipernowsky-Deri system. The station is established at Thorenberg ,where a waterfall of a force of 600 horse-power is utilised to drive two turbines. The installation comprises two alternative current machines making 250 revolutions per minute, and each one furnishing a current of 30 to 35 amperes with a difference of potential at the terminals of 1,800 volts. The two machines will supply current to 3,600 lamps of 10 candle-power, but only one machine will be used at first. The station is intended to supply various establishments in the vicinity.

THE TELEPHONE IN STOCKHOLM.—The telephone industry is making great headway in Stockholm. On the 15th of last January the *Stockholms Almanna Telefonaktiebolag* had 3,164 subscribers on its list, as against 2,335 on the 15th of January, 1885, and 865 on the 15th of January, 1884. During the past year, 4,772,760 messages were transmitted, of which 85,308 were during the hours of 10 p.m. and 8 a.m. The increase represents 100 per cent. The subscription amounts to about £7 per annum. Stockholm is telephonically connected with Södertelje, Monlbo, Trosa, Dolarö, Vaxholm, Rotebro, and Upsala, and other neighbouring villages. The greatest length of line is from Stockholm to Trosa, a distance of about fifty miles.

EDISON-SWAN LAMPS.—Speaking of Edison lamps Mr. Hartnell says, I have numbers of installations where after 1,500 and 2,000 hours' work but a very small number have given way, only a small percentage of what was originally put up. In one instance the lamps have run over 5,000 hours each. In another over 2,000 with a loss of not more than 15 per cent. In a third, the installation comprises some 70 lamps, and only 7 have actually burnt out after a run of nearly 2,000 hours. I could give innumerable instances where they have lasted considerably longer than what is usually calculated their nominal lifetime; but I need not add more than this, that they have come up to and even exceeded my expectations.

JUVENILE LECTURE.—A few evenings ago Mr. D. Lockhart, one of the clerks in the telegraph department at the Yarmouth Post Office, gave a lecture, entitled "An Evening with the Telegraph." To illustrate the subject, Morse's printer and sounder, Wheatstone's A B C, &c., and Daniell's batteries were used. Wires were led from one end of the room to the other, and messages were despatched and received, greatly to the amusement of the audience. Mr. Lockhart traced the development of electric telegraphy, and gave several very interesting facts connected with the sending of messages, the rapidity of transit abroad, the speed of deciphering and transcribing, the extent of wire now employed in the metropolis, and other statistics, all of which had a special interest.

FESTIVITIES.—The Leeds telegraphists held their annual *soirée* in commemoration of the transfer of the telegraphs to the Post Office, in the Albert Hall, Cookridge-street, on Thursday evening in last week. Mr. C. Holliday, day superintendent, presided, and was supported by Mr. J. C. Chambers and Mr. J. H. Naylor, superintending engineers. The whole proceedings passed off in a satisfactory manner.—The annual dinner of the telegraph clerks of the Eastern District, given by the Norwich telegraph staff, was recently held at the Shire Hall Tavern, Norwich, under the presidency of Mr. J. H. Ayers (superintendent of the Norwich staff), assisted by Mr. W. J. Power, of the engineering department, Norwich, the Colchester telegraph staff being represented by several delegates.

ELECTRIC LIGHT ON THE STAGE.—On the 18th and 25th ultimo, by permission of Mr. D'Oyly Carte, "Iolanthe" was played at the Vestry Hall, Anerley. In the last scene a capital effect was produced by the electric light. The fairy queen Iolanthe and three of the fairies had on their heads a light of two candle-power with a reflector behind the whole attached to a comb fastened in the hair. The sentry had a lamp of greater power on his busby. My Lord Chancellor, Lord Mountarat, Lord Tollsler, Strephon and Phyllis each wore a small hair filament lamp mounted in artificial flowers. Each actor carried a small accumulator capable of running the lamp two or three hours. The accumulators, lamps, &c., were supplied by Messrs. Woodhose and Rawson.

THE ELECTRIC LIGHT IN KIMBERLEY, SOUTH AFRICA.—At the annual meeting of the Kimberley Corporation the Mayor stated that a sum of £2,000 had been expended in the electric light department on additional plant and improvement of old plant, enabling the service to be extended by another 14 lamps and at very little extra cost for maintenance. Proposals had been made to light up the railway station by this department, but as yet no satisfactory reply had been received from Government on the subject. The system of private lighting on the incandescent principle had already been discussed by the Council, the adoption of which would no doubt prove a source of revenue. He further remarked that Kimberley is the only town in South Africa the streets of which are lit by electricity.

THE INTERNATIONAL ELECTRIC COMPANY.—It is notified in the London *Gazette* that a petition for the winding up of this company, subject to the supervision of Her Majesty's High Court of Justice, Chancery Division, was presented on the 3rd inst. by the International Electric Company (Limited), of No. 4, Copthall-buildings, and by Ernest Cooper, of 14, George-street, Mansion House, the liquidator of the said company; and that the said petition is directed to be heard before Mr. Justice Pearson to-morrow (Saturday), and any creditor or contributory of the company desirous to oppose the making of an order for the winding up of the company, should appear at the time of hearing for that purpose. A copy of the petition will be furnished to any creditor or contributory of the company requiring the same by Hollams, Son, and Coward, of Mincing-lane.

PURIFICATION OF SULPHURIC ACID. — Prof. Kupferschlaeger, in the *Bulletin de la Société Chimique de Paris*, says :—All chemists know that commercial sulphuric acid, prepared from iron pyrites, contains lead and calcium sulphates, nitrous and sulphurous vapours, arsenic acid, sometimes selenious acid, thallium sulphate, and hydrogen fluoride. For its purification he dilutes it with its own weight of water, then passes through it in excess a current of washed sulphurous acid, so as to bring the arsenic and nitric acids to a lower stage of oxidation, and to reduce selenious acid, if present. A current of hydrogen sulphide is then passed through it twice, with an interval, each time as long as it is absorbed. The vessel is then closed, and allowed to stand for some time at a moderate temperature, so that the lead and arsenic sulphides, selenium, &c., may subside. The sulphuric acid is then rectified in glass retorts, applying the heat so as to reach the upper portion only.

MINING EXPERIMENTS.—During the course of some experiments carried out recently at a North Staffordshire mine, for the purpose of demonstrating the efficiency of the water cartridge, a missed shot occurred which illustrated the value of electricity as a means of shot firing. In the case of an ordinary shot, with fuse missing fire, it is customary to withdraw the workmen from the place and not to resume until the next shift. With the use of electricity, however, the moment the wires are disconnected from the battery there is an absolute immunity from the danger of an unexpected explosion, and the shot may

Digitized by Google

be visited immediately, as was done in this instance. At the conclusion of the experiments Mr. Wynne, Government inspector, said that he was quite satisfied with what he had seen, and was prepared to report to the Home Office that the cartridge possessed that element of safety which was claimed for it. Mr. Wynne also referred to the question of firing shots by electricity, and hoped to see the system generally adopted.

Street Lighting in America.—The city officials of Baltimore have been investigating anew the subject of lighting streets in order to understand why that city has to pay so much more than other municipalities in this respect. Under the contract made early last year, Baltimore's cost of maintaining street gas lamps was $36·94 for each lamp per annum, burning only on dark nights, and $46·19 if allowed to burn all night. In comparison the following figures are collected, showing the amounts paid in other cities:—

New York	$25·00	Rochester	$18·12
Boston	31·85	Richmond	44·00
Washington	22·00	Dayton	21·11
New Orleans	24·00	Jersey City	25·00
Burlington	25·00	Cleveland	17·50
Auburn	17·50	Baltimore	46·19

New York has 23,038 gas lamps and 617 electric lights; Philadelphia has 13,555 gas lamps; Boston, 9,781 gas lamps and 401 electric lights; and Baltimore, 5,191 gas lamps and 243 electric lights.

The Telephone in Inverness.—Twelve months have now passed since the Inverness Telephone Exchange was opened for business. The progress which has been made during the year, and the amount of business transacted through the medium of the telephone is remarkably good. Beginning with 46 subscribers on its list, the number at the close of the year has increased to 67—an increase of 21. The total number of messages which have been transmitted through the Exchange during the year reached the grand total of 64,525. As the average time taken to transmit each message was about three minutes, and as 300 words can easily be exchanged in that time, it is calculated that no fewer than 19,357,500 words have been exchanged between the subscribers during the year. The network of wires which now passes through the town is a very satisfactory proof of the utility of the telephone system. The manager, Mr. R. C. Bennett, deserves credit for the manner in which the Exchange has been conducted.

Electric Illumination in Operations upon the Palate.—Mr. H. Morgan writes to the *Lancet* as follows:—"On Thursday last, having promised to perform an operation for the closure of a cleft palate, I found myself embarrassed by a failing light. Unwilling to postpone the operation, I gladly availed myself of the suggestion of Mr. Weiss, who was present, to use the electric lamp which he had been demonstrating to the students. Accordingly, having removed the mirror from one of Semon and Vesey's apparatus for illuminating the larynx, and which is supplied by four Leclanché cells, Mr. Weiss held the lamp just inside the mouth, and, by the beautiful, steady, and distinct light thus afforded, I was able to see clearly, better than even by the brightest daylight, and the operation was quickly and satisfactorily concluded. To those who, like myself, have had to postpone such operations, to the distress of the patient and at personal inconvenience, I feel sure that this new adjuvant will prove the greatest boon. The smallness of the apparatus makes it free from any inconvenience, and the almost entire absence of heat renders it void of danger, while the clear brightness of a steady light renders every step in this delicate operation more facile even to practised hands."

Patents and the Civil Service.—The Postmaster-General has reissued Section 27 of the Patents Act, 1883, with an amended notification relating to officers of the Crown who desire to take out patents as follows:—Any officer desirous of applying for a patent should, in the first instance, memorialise the Postmaster-General for his consent to the application, and should hand the memorial to the head of his department for submission to the Secretary. The memorial must contain, or be accompanied by, a statement of the nature of the invention or improvement. The Postmaster-General will, on receiving such application, specify the conditions on which he will give his consent. One condition of such consent being given will be that in any settlement of the terms for use by, or for, the Government of any such invention or improvement, regard is to be had by the Postmaster-General to any facilities in working out and perfecting the invention or improvement which the inventor may have enjoyed by reason of his official position. All communications on the subject of any invention or improvement will be treated as strictly confidential. Any officer applying for a patent without the consent of the Postmaster-General will be liable to be dismissed from the service of the Post Office.

The Electric Light for Steamships.—Messrs. Andrews and Co. have just completed an installation on board Messrs. Geo. Smith and Son's ss. "City of Bombay. The steamer has been fitted with the single-wire system, and the result has proved entirely satisfactory. In the saloon, state rooms, and music rooms, as well as in the passages, there are altogether fifty lamps on silver-plated pendants and brackets; while on the deck there are five cargo lamps, each of 50 candle-power, and the mast and side lights are each of two 50 candle-power lamps; one of each of these is, however, spare. In the engine room circuit, including the boilers and shaft tunnels, there are twenty-four lamps. The current is generated by two Andrews dynamos, type A, each capable of supplying eighty lamps, there being 112 on the whole ship. The vessel is furnished with considerable surplus lighting power. The same firm have also just finished a complete installation on board the largest steamer of the fleet of the Bedouin Steamship Company, of Liverpool. The lights are dispersed throughout the whole of the ship, including 50 candle-power lamps in the masthead, stern, and side lights. The installation consists of about 100 glow lamps, and the electricity is supplied by one of Andrews's slow-speed dynamos, driven by a Tangye engine.

Book Notices.—"The Electric Light in Workshops," by Charles Lever (Broadheath, Atlantic Printing and Publishing Company). This is a little *brochure* treating principally of the application of the arc lamp to the lighting of large works. In conclusion Mr. Lever has a word or two to say on the subject of some of the failures which have taken place in some works where the electric light has been introduced. These he attributes in the main to electric light charlatans. These gentry he says "are totally ignorant of electrical laws, and have had no experience in electric lighting. But they know how to talk, and sometimes receive an order to put up a few lights in a works as a result of their eloquent appeals. Having obtained the order, they send some inexperienced person (who has, probably, been induced to pay them £100 'to learn the business') to superintend a band of labourers, who are sent to carry out the installation, which, when completed, generally turns out to be a failure. Usually these men act as agents for some worthless system of electric lighting, the so-called patents of which are owned by a bogus company; or they content themselves by offering the 'latest' cheap and trashy dynamo or arc lamp which makes

Digitized by Google

its appearance. There is only one remedy against them, and that is to ask the contractor to guarantee his lights to be satisfactory. By this means a good and reliable plant can be purchased, for such plant, when put up by experienced men, is just as reliable as any other class of machinery." We quite agree with Mr. Lever.—"Electric Lighting in the United States," by Charles Lever (Altrincham: A. Ingham), as its title indicates, reviews the various systems of electric lighting in operation in America.

GRAPHICAL SIGNALLING.—The idea of graphical signalling recently described at the meeting of the Royal United Service Institution by Lieutenant Glen, of the Inns of Court Volunteers, and Colonel Melville, of the Engineers, to whom it had occurred independently, promises to be fruitful both of scientific interest and practical results. Its purport, in brief, is to make possible the communication of a diagram or drawing (including maps or sketch plans) whenever the despatch of messages by heliograph, flag-signalling, or any form of telegraphy is possible; and the essence of both Colonel Melville's and Mr. Glen's plans is the description of points by reference to co-ordinates, which is the method commonly used to fix places in the indices to an atlas. The problem is to make this method of reference available for signalling purposes. Colonel Melville's solution is the simpler; but Mr. Glen's has been more thoroughly worked out, and has two peculiar features of practical importance. The chances of error in transmission and the time occupied in signalling are reduced by devices for conveying the necessary information with a relatively small number of letter-signals. And by a still more ingenious device the points can be fixed on the diagram to any required degree of accuracy and the degree of accuracy changed in the course of the same message; so that a reconnaissance plan of country, for example, might be broadly sketched in and the details of buildings or fortifications more carefully given. The efficacy of the method has been proved by the severe test of transmitting portraits with no greater loss of fidelity than is commonly incident to reproduction by the usual printing processes. It is obvious that the message itself, as written down for transmission or by the receiver, is virtually a ciphered drawing, and might as such be useful even where communication by writing was practicable.

EARTH CURRENTS.—At the last meeting of the Royal Society of Edinburgh, a most interesting and suggestive paper on "Earth Currents on the Ben Nevis Observatory Telegraph Cable," by Mr. H. N. Dickson, was read by Prof. Chrystal:—"Disturbance of the telegraphic instruments at the Observatory by earth currents had frequently been observed, and the inference drawn from the disturbances was that the currents always existed, though with varying degrees of strength. Extending from about the middle of September till about the middle of October, 1885, a series of careful observations was made, with the view of determining, if possible, how far the disturbances were regular. By means of a galvanometer inserted in the telegraphic circuit, observations were taken every hour, and the results appeared to show that from midnight till four o'clock a.m. there was an earth current passing up the mountain, and reaching its first maximum about two a.m. This was followed by a slight return current down the line till about five o'clock, when a strong current up the line set in, which reached its maximum for the day at ten o'clock forenoon, and its minimum at one p.m. Subsequently the current increased pretty rapidly down the line again till three p.m., and became rather unsteady during the next five hours. Then an up-hill current steadily set in again, increasing till nine o'clock, and reaching its minimum at eleven p.m. While these observations were in progress the summit of Ben Nevis was almost continuously enveloped in storm and mist, whereby the results were, to some extent, necessarily affected. When the top of the mountain was clear it was observed that there was a strong current passing up the cable, the current being reversed when the opposite condition of things prevailed. The current was always found to be down the line during a fall of snow. In the opinion of Prof. Chrystal, these results opened up an interesting field in electrical science, which could only be thoroughly investigated by help from Government. One thing required would be to obtain possession of a land line to make experiments as to the effect of earth currents along the horizontals. M. Sang said that the results detailed in the paper materially affected the results of the determination of the earth's density by means of a plummet. The deviation of the plummet on which those results were based might be caused entirely, he thought, by the presence of the currents spoken of."

PROGRESS IN THE NORTH OF ENGLAND.—We understand that during the past year Mr. Wilson Hartnell, of Leeds, erected some twenty installations. Of these, eighteen were on the incandescent system. One of the largest plants put down is that at Wentworth Castle, which comprises upwards of 400 lamps. The plant, which is sufficient for 650 lamps, consists of two Crompton compound dynamos, driven from a countershaft by two of Marshall's horizontal engines, fitted with the Hartnell patent governors. The steam is supplied by two steel Cornish boilers. The castle is lighted from cellar to roof, including conservatory and other adjoining buildings, and it is considered to be one of the largest and most complete installations in the North of England. There are seven installations in corn mills, where the dynamos are required, for the most part, to run all night; hence great care is needed in fixing, and the work must necessarily be well done to insure thorough success. Four installations are in woollen mills, one in a large cotton daubling concern, one large arc installation at Marshall's, Gainsborough, and two in paper mills, besides three private houses. All the dynamos used are of the compound type, except in the case of Colonel Brooke, at Huddersfield, where a shunt-wound dynamo and accumulators are employed. In one case both arc and incandescent lamps are driven from one machine, on separate circuits, and the result has been extremely satisfactory. One of the paper mills mentioned has some 350 lamps in all, driven from one machine by a special engine. The works cover a very large area, several acres, and are lighted throughout by Swan lamps by the single dynamo, and their gas plant has been superseded entirely. At Messrs. Marshall, Sons, and Co. there are some thirty arc lamps of the Crompton-Crabb double differential type, with a current of from sixteen to twenty amperes each, driven from a compound-wound machine. In this installation a somewhat novel and very effective method is introduced, that is, of grouping the lamps in sets of five, so that any set of five may be turned off at pleasure without interfering with the remainder, and that at the same time the power absorbed shall diminish in the same proportion. On this system any number of arc lamps may be driven from a single dynamo without a dangerous amount of electromotive force on the one hand or undue cost for leads on the other. In this case it was most difficult to get the work done at times in the erecting shop, but since these lamps were put in work has been carried on at night the same as with daylight. In the corn mills the chief feature is the cleanliness and non-liability to explode, but in addition to this it has been proved abundantly that where the dynamos have proper attention the incandescent system is much cheaper than gas.

COMMON MISTAKES IN ELECTRICITY AND MAGNETISM.

BY G. W. VON TUNZELMANN, B.SC.

II.—FRICTIONAL ELECTRICITY.

In a former paper (*Electrician*, Vol. XV., page 94) I called the attention of teachers and others to some of the mistakes most commonly made by beginners in the study of magnetism. In the present paper I shall note in the same way some frequently recurring misapprehensions and difficulties with regard to simple electrical phenomena.

First Ideas of Electricity.—It is most important that the student should not be introduced to any theory of electrification until he has a thorough grasp of the elementary experiments from which it is deduced that there are two distinct kinds of electrification, that the electrification of a body is a physical quantity capable of measurement, and that the two distinct kinds of electrification stand in the same relation to each other as positive and negative algebraical quantities. It should also be pointed out to him that the decision as to which kind of electrification should be considered positive is purely arbitrary, but that for convenience in comparing different results a choice has been made once for all, and is always adhered to, viz., that the electrification produced on glass by rubbing it with silk is to be called *positive*, and the electrification produced on resin or sealing wax by rubbing it with silk is to be called *negative*.

Insulation.—It should be noted that when we speak of such bodies as silk, glass, resin, &c., as being non-conductors of electricity, or insulators, we really mean that they only conduct electricity with extreme difficulty, so that, strictly speaking, they are *very bad conductors*, and not *non-conductors*; but, bearing this in mind, it is convenient to use the expressions. In the case of air and other gases, *either dry or moist*, at pressures not greatly exceeding that of the atmosphere, we have not been able to obtain any evidence of electricity passing through them by ordinary conduction, and therefore they may with perfect strictness be called non-conductors or insulators.

It is a very common mistake that the difficulty of maintaining the electrification of an electric machine or other apparatus in damp air is caused by damp air being a good conductor of electricity. The true explanation is, that when the apparatus is exposed to damp air a thin film of water is condensed on the exposed portions of the apparatus, including the insulating supports; and water, we know, is a good conductor of electricity.

A good experimental illustration of this is given by Maxwell. Let two insulated conductors be placed in close proximity, and first charge them similarly and afterwards dissimilarly, making the charges in the two cases equal, noting in each case the time which elapses before the electrification disappears. It will be found that the conductors will retain their electrification longer when dissimilarly charged, because the electromotive force through the supports is less in this case, while when they are similarly charged the electromotive force is less through the air between them and greater through the supports.

Distribution of Electricity in Equilibrium.—It is shown experimentally that if a charged conductor be placed inside, and in contact with a closed hollow conductor, it will give up the *whole* of its charge to the conductor which encloses it, provided there are no electrified bodies within the hollow conductor, which are separated from it by an insulating medium.

From this experiment it can be shown mathematically that the law of electrical repulsion must be that of the inverse square of the distance.

The statement that "the electricity of a charged conductor, when it has attained its final distribution, is entirely upon the surface of the conductor" should, therefore, be simply presented to the student as a direct inference from the above experiment, and the teacher should guard against attempting to give a vague explanation that it is due to the self-repelling character of electricity. Such an explanation sounds plausible, but it is entirely misleading, for the result would not be obtained if the law of repulsion were other than that of the inverse square.

Dispersion of Electricity by Points.—Every learner knows as an experimental fact that electricity escapes more readily from a pointed portion of a conductor than from a rounded portion, but I have noticed that a large proportion are unable to give any reasonable explanation of it.

Now, the fact that the electric charge is found entirely on the surface of a conductor shows that at every point of the electrified conductor there is a force, due to the electrification of the rest of the conductor, acting outwards upon the electricity at that point, and it is clear that this force is perpendicular to the surface of the conductor, for otherwise it would have a component along the surface, and this component would cause a flow of electricity within the conductor.

Again, if an insulated charged conductor, rounded at one end and pointed at the other, be tested by means of the proof plane, a greater charge is obtained near the pointed end than near the rounded end, showing that a small portion of the surface near the pointed end carries a larger charge than an equal small portion near the rounded end.

Now, the *electric density* is defined as the charge on an indefinitely small portion of the surface divided by the area of that small portion. This experiment, therefore, shows that the electric density is greatest where the conductor is most pointed. But this accumulation of electricity is caused by the repulsive force exerted by the electricity distributed over the remaining portion of the conductor, and therefore we see that the repulsion acting on a unit quantity of electricity must be greatest at the most pointed end. Since the charge per unit of area is greatest when the conductor is most pointed, and the repulsion on each unit of electricity is greatest at the same place, it follows *a fortiori* that the force acting outward per unit of area of the surface or the *electric tension* is greatest at the pointed end. By increasing the sharpness of the pointed end the electric tension may be increased, until it becomes sufficient to break down the resistance of the insulating medium, allowing the electricity to escape.

Electrical Induction.—A very large proportion of the misapprehensions of learners arise from their not having properly understood the experiments shown them to illustrate *electrical induction*, which may be defined as the movement of electricity in a conductor, caused by external electricity.

They should be made to understand that when a light body such as a pith ball is attracted to an electrified body held near it, it is because it is first electrified by induction. It should be pointed out to them that if the pith ball be lying on a conductor it will become oppositely electrified to the inducing body, while if it be insulated it will become oppositely electrified on the side nearer to the inducing body, and similarly electrified on the further side, but that the opposite charge being nearer to the inducing body than the equal similar charge on the further side, the attraction will be greater than the repulsion, and the resultant of these two oppositely directed forces will therefore again be an attraction, but weaker than in the former case.

Action of Lightning Conductors.—The student should have it fully explained to him that the object of placing lightning conductors near buildings, or attaching them to the masts of ships, is not primarily to make the lightning strike them rather than the objects to be protected, but by allowing a free flow of electricity from the earth or sea by means of the pointed extremity, to prevent the earth or sea in the neighbourhood from becoming strongly electrified by the induction of the electrified clouds above, for if this be prevented no lightning discharge can take place. If, however, the conductor is unable to discharge the electricity of the earth with sufficient rapidity to prevent the passage of lightning from the cloud, the lightning will strike the conductor rather than the building, which is the same thing as saying that if a disruptive discharge does take place it will be from the extremity of the conductor rather than from any neighbouring point, because that is where the electric tension is greatest.

The student should be impressed with the importance of the earth connection being good, and should understand that a lightning conductor with a bad earth connection is useless.

The Leyden Jar.—The theory of the Leyden Jar presents no difficulty when the principles of electric induction are properly understood, but beginners show a great tendency to ignore the fact that its action is entirely due to induction, and they often seem to imagine that electricity can be poured into the jar much as water is poured into a bottle.

To obviate this, the teacher should be careful that the student fully understands electrical induction before any attempt is made to explain the action of the jar, and as an additional safeguard against his attributing any magical influence to the jar form, I think it preferable first to make him familiar with the action of a condenser in some other form, such, for example, as two sheets of tinfoil pasted on opposite sides of a thick sheet of glass. It can then be explained to him that the condenser is commonly made in the form of a jar, because, for many purposes for which condensers are required, it is the most convenient shape.

It is also as well to point out that the jar is really complete as a condenser when the two coatings of tinfoil have been applied, and that the metallic ball in electrical communication with the inside coating, with which the jar is usually provided, is simply an extension of the inside coating, as a matter of convenience, to afford a ready means of approaching it to other electrical apparatus.

CORRESPONDENCE.

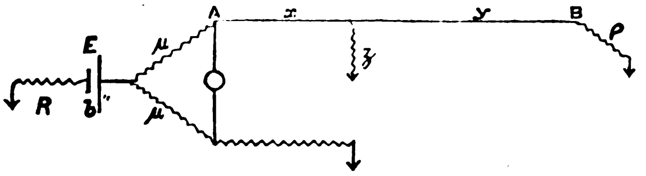
FORMULÆ FOR MAINTAINING THE CONSTANCY OF TESTING CURRENTS THROUGH A FAULT IN BLAVIER LOCALISATION MEASUREMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read with interest Mr. H. Kingsford's paper on "Localising a Cable Fault by Tests from One End Only," as it appeared in *The Electrician* of the 18th inst., I have ventured to draw up from it and from the general literature of the subject—notably the late Mr. Schwendler's work on testing—a set of formulæ which will, I trust, form a concise and useful reference for such of your readers as are practically interested in fault localisation.

Even when every care is taken with the measurements of a Blavier test, and every efficient correction has been introduced, electricians prefer, I think, to place more reliance upon some method of localisation dependent on simultaneous observations from both ends of the cable, such as "potential" tests, "overlap" tests and the like; but since such co-operation from the distant end cannot in all cases be obtained, and since without such co-operation the Blavier method is, so far as we know, the only one by which the measurement of resistances at one end alone indicates the distance of the fault, it is of considerable importance to raise as far as possible the standard of accuracy in the Blavier method, and we owe, I think, to Mr. Kingsford a convenient means of eliminating its principal source of error—the variation of the fault's resistance with the change of current passing through it in the different measurements.

As it sometimes happens, especially in cable repairing, that the normal conductor resistance of the cable between the ends is not accurately known, we shall introduce formulæ to deal with such cases, as well as the simple condition when the normal conductor resistance is given.



Let A B be a cable of conductor resistance $(x+y)$, and with one fault of resistance z, situated at distances of x and y ohms from A and B respectively. Suppose that A only can measure resistances by a Wheatstone bridge, as shown, where $\mu\,\mu$ are the equal arms; also a battery of electromotive force E and internal resistance b with an adjustable resistance R in the earth wire.

B cannot take measurements, but can alter the electrical condition of his end by the interposition of a known variable resistance ρ between it and earth. To free the cable, this resistance is made infinity; to put the cable to earth, it is made zero, while between those limits any convenient concerted value, ρ, can be brought in circuit.

Let us also assume that A takes all measurements to "false" or earth-current zero, and that the resistance z of the fault is constant for a constant testing current traversing it.

Then, since the variation of ρ at B must alter, other things being equal, the current strength in z, it will be necessary to maintain that strength uniform that a corresponding inverse change be produced in the strength of the outgoing testing current at A. This can be done in three ways:—

1st. By varying the electromotive force E.

2nd. By introducing a variable resistance into the circuit.

3rd. By establishing a variable derived circuit at some point in the system to carry off the superfluous current from the line.

Of these three methods we shall only examine the first two, as the third is the most complicated and the least advantageous.

To maintain a constant current in the fault by varying the testing electromotive force.

This corresponds to the case of a single Wheatstone bridge at station A, and a battery of a variable number of cells with no available rheostat, R.

We shall consider the cases—

1st. When the normal conductor resistance $(x+y)$ is unknown.

2nd. When $(x+y)=l$ a known quantity. At present we suppose that in the figure $R=0$.

1st. Let B during arranged intervals free his end $(\rho=\infty)$, then introduce a specified resistance to earth, ρ, and then earth direct $(\rho=0)$.

Let f, r, and e be the first set of measurements taken at A (with the same battery), corresponding to those conditions at B respectively. Then from Schwendler's equations the first preliminary values of x, y, and z have to be found as follows—

$$x=f-\sqrt{\frac{(f-r)\,(f-e)\,\rho}{r-e}} \quad . \quad . \quad . \quad (1)$$

$$y=\rho\left(\frac{f-r}{r-e}\right)-z \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$z=f-x. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Now fix upon a suitable number of cells to employ in the measurement of r, and let N_r be that number. Then the correct numbers of the cells to be used in observing f and e, while maintaining a uniform testing current in the fault will be—

$$N_f=N_r+\frac{k}{k+z\,(\mu+x)+2\,z\,N_r\,b} \quad . \quad . \quad . \quad (4)$$

and

$$N_e=N_r+\frac{k+\frac{z}{y}\,(\mu+x)\,(y+\rho)}{k+z\,(\mu+x)-2\,\frac{z\rho}{y}N_r\,b} \quad . \quad . \quad . \quad (5)$$

where b is the resistance of each cell, and $k=(y+\rho)\,(\mu+x+z)$.

When Minotto cells are employed, or when the resistances of $\mu\;x\;y$ and z are not relatively large to the internal resistance of the batteries, these formulæ may have to be employed; but in most cases, with a suitable battery, its internal resistance may be neglected, and the equations then become:

$$N_f=N_r\times\frac{k}{k+z\,(\mu+x)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

$$N_e=N_r\times\frac{k+\frac{z}{y}\,(\mu+x)\,(y+\rho)}{k+z\,(\mu+x)} \quad . \quad . \quad . \quad (7)$$

where $k=(y+\rho)\,(\mu+x+z)$

As these equations seldom yield whole numbers, the nearest integer has to be accepted.

Digitized by Google

A second set of f r and e has now to be taken with the batteries of N_f N_r and N_e cells respectively, and the readings so obtained may be denoted by f_1, r_1, and e_1.

Substituting these values in equations (1), (2), and (3), the first approximation to the true values of x, y, and z will be obtained, namely, x_1 y_1 and z_1, which by the use of equations (4) and (5), or (6) and (7), will supply new values of N_f and N_e to be employed in measuring f_2 r_2 and e_2.

This process of approximation has to be carried on until two consecutive sets f r and e are alike. These sets should then supply the true values of x, y, and z.

If, as has been assumed, the resistance of the fault is steady under a constant testing current, in most cases the second approximation will be sufficient to fix x, y, and z, with all the accuracy that the conditions of the test supply—in other words, the calculation will cease at f_3, r_3, and e_3.

But if, as frequently happens, the resistance of the fault is not steady under a constant testing current, then the equality of f_n, r_n, and e_n with f_{n-1}, r_{n-1}, and e_{n-1} cannot be expected, however great n may be; but a mean value of each is to be hoped for which will probably supply results for x, y, and z nearer to the truth than if no approximation had been attempted.

It is evident from equation (1) that the best value to give ρ is generally such as will make r approximate to $\frac{f+e}{2}$.

We may illustrate the case by an example. Suppose that A with the same battery power took the preliminary measurements of f, r, and e, as follows :—

$$f=1200\omega, \quad r=955\cdot0\omega, \quad e=760\omega; \quad \text{while } \rho \text{ was } 1000\omega.$$

From these values and equations (1), (2), and (3), the first results are

$$x=456\cdot5\omega, \quad y=513\omega, \quad z=743\cdot5\omega.$$

Next suppose that A had a number of cells each of one volt E.M.F. and ten ohms internal resistance, and that he selected twenty for the measurement of r, also that the arms of his bridge were 1000ω each.

Then by formulæ (6) and (7)

$$N_f=14\cdot193, \text{ and } N_e=31\cdot698.$$

A would then repeat the measurement of f r and e with 14, 20 and 32 cells respectively.

Suppose that the readings he then obtained were

$$f_1=1200\omega, \quad r_1=933\omega, \quad e_1=743\omega.$$

By equations (1) (2) and (3) as before, these values give

$$x_1=398\cdot6\omega, \quad y_1=603\cdot6\omega, \quad z=801\cdot4\omega.$$

Substituting again in equations (6) and (7)

$$N_f=15\cdot18, \text{ and } N_e=27\cdot99.$$

Repeating the measurements with 15, 20, and 28 cells suppose A found

$$f_2=1200\omega, \quad r_2=933\cdot3\omega, \quad e_2=742\cdot9\omega.$$

These figures, substituted in equations (1), (2), and (3), give

$$x_2=400\omega, \quad y_2=600\omega, \quad z_2=800\omega.$$

And those again in equations (4) and (5) give

$$N_f=14\cdot193, \text{ and } N_e=31\cdot698.$$

Repetition of f, r, and e, with 14, 20, and 32 cells, may be supposed to have given

$$f_3=1200\omega=f_2, \quad r_3=933\cdot3\omega=r_2, \quad e_3=742\cdot9\omega=e_3.$$

So that x_2, y_2 and z_2 would be the final results, and the testing current through the fault in measuring f_3, r_3, and e_3 would be approximately 5·7 milliamperes in each case.

Practically we could seldom expect to arrive at the true values of x, y, and z so closely as we have traced them in the above example; but we should certainly expect to arrive at more accurate results than if we employed the same battery power for all measurements.

2nd. When $x+y=l$ a known quantity. B need in this case free and earth only, and A will first observe preliminary values of f and e with the same battery power.

These will supply the first results for x, y, and z by the ordinary formulæ

$$x=e-\sqrt{(f-e)\ (l-e)} \quad \ldots\ldots \quad (8)$$

$$y=l-x \quad \ldots\ldots\ldots\ldots \quad (9)$$

$$z=f-x \quad \ldots\ldots\ldots\ldots \quad (10)$$

A suitable number of cells has then to be selected for measuring f or e. Suppose we take a certain number, N_f, for the observation of f, then

$$N_e=N_f\times\frac{p+\frac{z}{y}(\mu+x)}{p-2N_f b\frac{z}{y}} \quad \ldots\ldots \quad (11)$$

where $\quad p=\mu+x+z$

and when the resistance of the battery is low relatively to the other values, and may be neglected, then

$$N_e=N_f\times\frac{p+\frac{z}{y}(\mu+x)}{p} \quad \ldots\ldots \quad (12)$$

b is the resistance of a single cell, as before.

A now repeats the measurement of f and e with N_f and N_e^1 cells respectively, observing values f_1 and e_1, which by equations (8), (9), and (10) will give more approximate results for x, y, and z, namely, x_1, y_1, and z_1. And, as in the first case, the approximation is continued until f_n and e_n are the same as f_{n-1} and e_{n-1}, when both sets should yield correct results for x, y, and z.

We may illustrate this case by another example. Suppose that with the same battery A finds

$$f=1050\omega, \quad e=840\omega, \quad \text{when } l=1000\omega.$$

Then by equations (8), (9), and (10) these make

$$x=657\omega, \quad y=343\omega, \quad z=393\omega.$$

Now, suppose A selects 10 cells of 10 ohms each, to employ in observing f, while the ratio of his bridge remains at $1000\omega : 1000\omega$, then by equation (12) the above values of x, y, and z give

$$N_e=19\cdot263.$$

A then observes f_1 and e_1 with 10 and 19 cells respectively, and, say, he finds

$$f_1=1080\omega, \quad \text{and } e_1=831\cdot5\omega.$$

These figures give by equations (8), (9), and (10)

$$x_1=626\cdot4\omega, \quad y_1=373\cdot6\omega, \quad z_1=453\cdot6\omega.$$

Substituting those again in formula (11),

$$N_e=22\cdot06.$$

A now observes f_2 and e_2 with 10 and 22 cells.

Suppose that he then finds

$$f_2=1100\omega, \quad e_2=822\cdot2\omega.$$

From these and equations (8), (9), and (10)

$$x_2=600\omega, \quad y_2=400\omega, \quad z_2=500\omega.$$

Substituting in equation (11)

$$N_e=22\cdot162$$

Repeating f and e with 10 and 22 cells, A would probably find

$$f_3=1100\omega=f_2, \quad e_3=822\cdot2\omega=e_2$$

and x_2 y_2 and z_2 would be the accepted results. Also if each cell had an electromotive force of one volt the current flowing through the fault would be approximately 4·3 milliamperes in observing both f_3 and e_3.

To maintain the current in the fault constant by the introduction of a variable resistance into the circuit.

The variable resistance has to be introduced at A either between the bridge and cable, or between the bridge and earth. If in the former position, the amount of compensating resistance introduced must always be twice the amount necessary if introduced in the latter position (when the ratio of the bridge arms is unity). For instance, 2000ω between the cable and bridge has the same effect as 1000ω in the earth wire, so that the figure shows the simpler fundamental con-

Digitized by Google

ception, and all values that we shall find for R will correspond to 2 R added to the cable, if that position for the rheostat is preferred.

1st. When the normal conductor resistance $(x+y)$ is unknown.

B frees, earths through a resistance ρ, and then earths direct, just as in the first case considered, while with the same battery and R either zero or constant, A observes the preliminary values of f, r, and e.

By equations (1), (2), and (3) these will supply the first values of x, y, and z.

A now selects a suitable battery-power with which to observe e while $R=0$. Then the values R_f and R_r to be given to R, so that in all three measurements the testing current through the fault may be constant, are

$$R_f = \frac{z\,(2\,b+\mu+x)}{2\,y} \quad \ldots\ldots \quad (13)$$

$$R_r = \frac{z\,\rho\,(2\,b+\mu+x)}{2\,y\,(y+\,.\,z+\rho)} \quad \ldots\ldots \quad (14)$$

so that

$$R_f = R_r\left(\frac{y+z+\rho}{\rho}\right) \quad \ldots\ldots \quad (15)$$

where b is now the internal resistance of the whole battery.

A now repeats the measurement of f, r, and e, making $R=R_f$, $R=R_r$, and $R=0$ respectively. Let f_1, r_1, and e_1 be the measurements so obtained. By equations (1), (2), and (3) these give x_1, y_1, and z_1, and these again supply more approximate values of R_f and R_r. Proceeding in this way, if the fault's resistance is constant for a constant current, we may expect to find a set f_n, r_n, and e_n, equal to f_{n-1}, r_{n-1}, and e_{n-1}, when x_{n-1}, y_{n-1}, and z_{n-1} will be the final results.

We may illustrate the case by an example. Suppose that with $R=0$, and one battery A finds the preliminary values of f, r, and e as follows :—

$$f=1500\omega,\quad r=1134\omega,\quad e=853\omega,\quad \text{while } \rho=1000\omega.$$

By equations (1), (2), and (3),

$$x=582\omega,\quad y=384{\cdot}5\omega,\quad z=918\omega.$$

By equations (13) and (14),

$$R_f=2127\omega,\quad R_r=924\omega,$$

A now selects a battery for the measurement of e, with an internal resistance of 100ω, when $R=0$, and then repeats f, r, and e with R_f and R_r. Suppose he obtains

$$f_1=1500\omega,\quad r_1=1115\omega,\quad e_1=844\omega.$$

From these, by equations (1), (2), and (3),

$$x_1=534{\cdot}6\omega,\quad y_1=455{\cdot}3\omega,\quad z_1=965{\cdot}4\omega.$$

By equations (13) and (14),

$$R_f=1839\omega,\quad R_r=760\omega.$$

Introducing these resistances, A repeats f, r, and e, and finds, say,

$$f_2=1500\omega,\quad r_2=1100\omega,\quad e_2=833{\cdot}3\omega.$$

By equations (1), (2), and (3),

$$x_2=500\omega,\quad y_2=500\omega,\quad z_2=1000\omega.$$

And by equations (13) and (14)

$$R_f=1700\omega,\quad R_r=680.$$

We may now suppose that A, on repeating f, r, and e, finds

$$f_3=1500\omega=f_2,\quad r_3=1100\omega=r_2,\quad e_3=833{\cdot}3\omega=e_2.$$

Then x_2, y_2, and z_2 would be the accepted values, and with an electromotive force of twenty volts in the testing battery the testing current through the fault would be approximately 3·28 milliamperes in each observation of the last set.

2nd. When the normal conductor resistance $(x+y)=l$, a known quantity.

B frees and earths direct, while with one battery and R constant or zero, A measures the preliminary values of f and e. From these and equations (8), (9), and (10), the first values of x, y, and z are found. A then selects a battery of internal resistance b, for the measurement of e with $R=0$, and then the value of R to insert when measuring f is given in equation (13). New readings, f_1 and e_1, are then taken, and new values, x_1, y_1, and z_1, found. As before, approximation has to continue until f_n and e_n equal f_{n-1} and e_{n-1} respectively, when x_{n-1}, y_{n-1}, and z_{n-1} are the final results. If the fault's resistance is not constant for a constant traversing current, then, as we have already remarked, this equality cannot be expected, and a mean value only of all the quantities involved is to be hoped for, this mean result for x, y, and z being probably more accurate than if no approximation had been attempted.

A final example may illustrate this last case.

Suppose that with one battery of 100ω internal resistance and $R=0$, A found the preliminary values of f and e (l being 1000ω)

Then by equations (8), (9), and (10)

$$f=1100\omega,\quad e=887{\cdot}5\omega.$$

$$x=733\omega,\quad y=267\omega,\quad z=367\omega,$$

These values and equation (13) give

$$R_f=1233\omega.$$

A now repeats f and e, with $R=1233\omega$ and $R=0$. Suppose he finds

$$f_1=1180\omega,\quad e_1=887{\cdot}5\omega.$$

Then by equations (8), (9), and (10)

$$x_1=706\omega,\quad y_1=294\omega,\quad z_1=474\omega.$$

Which by equation (13) supply

$$R_f=1536\omega.$$

A now repeats f and e, with $R=1536\omega$ and $R=0$. Suppose he obtains

$$f_2=1200\omega,\quad e_2=887{\cdot}5\omega.$$

Then by equations (8), (9), and (10)

$$x_2=700\omega,\quad y_2=300\omega,\quad z_2=500\omega,$$

and these values in equation (13) give

$$R_f=1583\omega.$$

A now repeats f and e, with $R=1583\omega$ and $R=0$. Suppose he obtains

$$f_3=1200\omega=f_2,\quad e_3=887{\cdot}5\omega=e_2.$$

Then the accepted final values of x and y would be 700ω and 300ω respectively, while in observing f_3 and e_3 with an electromotive force of twenty volts in the battery, the current in the fault would be 3·6 milliamperes in each case.

We have now considered both methods of maintaining a constant current in the fault. The first, by a variable electromotive force, is given in outline in the work on "Testing," by the late Mr. Schwendler. The latter, by a variable resistance, is developed from Mr. Kingsford's paper already mentioned. Of the two, it is the more convenient, practically, and involves less arithmetical labour; but, where no rheostat is available, Schwendler's method has to be adopted.—Yours, &c.,

A. E. Kennelly,

Lisbon, 29th December, 1885.

THE DYNAMO AS A GENERATOR AND A MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir : I have been vastly interested in the articles on "The Dynamo as a Generator and a Motor," and my experience (which extends over the last fourteen years), to a great extent, has been the same as Sir David's in the matter of the best generator making the best motor. I can quite agree with Mr. Walker that we have not advanced much the last eight years. The fact that I have discovered in the course of my experimenting with all sorts of shapes of motors is that the generator in *general* shape is the right one, but has to be slightly altered in details when used as a motor; when a motor is so altered there is a gain of 30 per cent. in the output with the same strength of current. As I could not give these details without trespassing too much on your valuable space, I will send them to any manufacturer of motors who will write to my address.—Yours, &c.,

Wm. Aldred.

PROFESSOR HUGHES' NEW DISCOVERIES.

It has often been said that any scientific observer who deserves to be called "keen" in the popular sense of the term, and not merely "close" in the scientific sense of it, must be one who, while keeping his main object constantly in view, takes notice of everything he meets in his pursuit of it. For such a man nothing is overlooked by the way; new facts are noted down, every strange phenomenon is treasured for future investigation, and nothing is neglected as trivial. Professor Hughes is an observer and experimenter who answers to both these descriptions; he has a keen eye for results, and a close one for accidentals on the road. The incident of the sounding box mentioned during the presidential address the other evening, though not described in the printed paper, was an illustration of this. The Induction Balance itself, which was the instrument employed for making the discoveries laid before the Society of Telegraph-Engineers and Electricians, may be cited as the result of a similar accident falling under the notice of a man who has eyes to see and the genius to appreciate its significance. This contrivance was for a time chiefly remarkable for its extreme sensibility; its utility was by no means so evident, and although in the inventor's hands its performances were startling enough, there prevailed a pardonable scepticism as to its usefulness in anybody else's. Even when manipulated by himself its revelations seemed, to say the least, ambiguous, and though they pointed plainly to somewhere, nobody but himself, perhaps, could see precisely to where. Presently the accumulation of observations removed this uncertainty to a great extent, and now whenever Prof. Hughes announces another instalment of his experiments the public confidently expect to be taken appreciably nearer a solution of the mystery of magnetism and the hardly less mysterious phenomenon of electricity. Thanks to an ingenuity which is almost as remarkable as his insight, he is able to sustain this interest, not only by fresh revelations but by making them perfectly intelligible.

The chief value of the latest of these contributions probably is in their practical bearing upon the erection and material of telegraph and telephone wires. Indirectly they will throw some helpful light on the construction of dynamos, and not improbably, we think, on the manufacture of submarine cables, though the lecturer himself did not explicitly refer to either of these important industries. Considerable uncertainty has long prevailed as to the true character of induced currents and their relation to the conductor, to say nothing of the extra currents and retardation which are among the chief troubles of electric telegraphy. By a singularly bold and ingenious adaptation of the Wheatstone bridge principle, combined with his Induction Balance, Prof. Hughes has contrived a method of investigation which promises fairly to set these doubts at rest. Using, as throughout all his recent experiments he has done, the telephone as the tell-tale instead of the galvanometer, which would be useless in this connection, he is able to detect the nicest differences in wires of different material and varying dimensions, and by means of the sonometer with its movable indicator, to measure exactly the proportional variations of current induced in the wire experimented upon. It has long been suspected that the so-called resistance of any conductor differed when under the influence of a rise and fall of the current. The stable period is arrived at by maintaining a continuous current, and it is at this point that resistance is usually measured. But when used for telegraphic, telephonic, or electric lighting purposes rapid variations occur which give rise to the phenomena of induction; and it is then that, as Prof. Hughes has demonstrated, considerable difference in the normal resistance of the wire sets in, and the effect is aggravated by every additional electro-magnetic coil in the system. He finds that iron telegraph wire under rapid currents with which it is worked has a resistance three times greater than what is supposed to be its true resistance. And as the variation between the two periods differs in different classes of conductors, it follows that the ordinary resistance tests, regarded as a criterion of working capabilities, may be and probably often are somewhat illusory.

For various reasons, made conclusive by these experiments, iron is seen to be far inferior to copper both as a conductor and on account of its susceptibility to self-induction. Except in the stranded form, in which condition it is nearly equal to copper, iron exhibits the greatest electromotive force for the extra current, whilst German silver, mercury, and carbon exhibit the least, copper occupying a position very little above them. But this is true of wires only of similar dimensions; for it is found that above a certain maximum diameter of wire a marked decrease in the electromotive force of the induced current takes place with each further sectional increase, and that the maximum varies in different metals. It is also noticed that in telephone circuits, when a return parallel wire is used, the extra currents are reduced only fifteen per cent. in the case of iron, whereas a diminution of eighty per cent. is obtained when the wires are of copper. Moreover, iron wire, besides being peculiarly sensitive to all physical changes, which have, as the Induction Balance shows, a marked influence on electrical self-induction, is greatly affected by its magnetic condition. To quote the lecturer's own words, "Iron well annealed has much less resistance than the same iron when

Digitized by Google

hard drawn, and soft iron is generally employed for telegraph lines; but during the variable period"—that is, during the actual working period—"a curious reversal takes place, as then soft iron has a higher resistance than hard iron. This apparent anomaly is easily explained if we compare the far higher self-induction of soft iron. Work is done at the expense of electrical energy, and the apparent higher resistance is due to the greater electro-magnetic action in soft iron. An iron wire shows traces of remaining circular magnetism after the passage of a continuous current, reducing the following extra currents 10 per cent." Subjected to mechanical vibrations, as are to some extent all suspended wires, iron betrays, under the influence of reverse currents, properties which materially impede the speed of telegraphic signalling. Generally speaking, Prof. Hughes favours those telegraph instruments which require only a single current for each letter, as they tend to lessen the practical difference arising from the use of iron wire and copper wire.

Some very instructive facts were also made known as to the relative merits of wire of different structure. We have already alluded to the stranded wire. It is stated sixteen fine iron wires twisted together as a stranded wire have eighty-eight per cent. less induction than a solid wire of similar weight. This difference, however, is not nearly so marked in the copper wire, for reasons which are sufficiently explained by its non-magnetic character, although it still maintains its relative superiority over iron. But the comparison between circular and ribbon wire is of still greater interest. The advantages of the latter have been already suspected, and Prof. Hughes has now computed and explained them. By employing ribbon conductors the self-induction is reduced eighty per cent. in iron, and thirty-five per cent. in copper; and, in short, there are good grounds for concluding that the resistance of a conductor, or the metal of which it is composed, have less influence on its self-induction than has the form of the conductor. This circumstance has an important application in the winding of electro-magnetic coils, but especially in the construction of lightning conductors. These experiments have confirmed the opinion that a solid rod of iron is the worst possible outlet for lightning discharge. The conductor, if of copper, should be of ribbon form, or if of iron, of numerous stranded wires, or a wide ribbon of similar conductivity to that of copper. Prof. Hughes's paper was discussed last night while we were going to press; but whatever criticism it may have been subjected to on certain points, there will be no difference of opinion as to the great practical value of the discoveries he is making by the assiduous use of his exquisite little instrument, the Induction Balance.

NOMENCLATURE.—III.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I number this III. as being my third note on the subject. In my first, amongst other things, I remarked that whilst the conduction current terminology admitted of the words resistivity and conductance being coined to make it more complete, the terminology in the allied cases of magnetic induction and electric displacement was unsatisfactory.

As regards the former, the following appears to me to be practical. First, abolish the word permeability, and substitute Inductivity. We then have $B=\mu H$, when B is the Induction, and μ the Inductivity, showing how the Induction is related to the magnetic force H by the specific quality of the medium at the place, its inductivity.

Now conductivity and conductance are mathematically related in the same manner (except as regards a 4π) as inductivity and what it is naturally suggested to call Inductance.

The Inductance of a circuit is what is now called its coefficient of self-induction, or of electromagnetic capacity.

Thus the quantities induction, inductivity, and inductance are happily connected in a manner which is at once concise and does justice to their real relationship. When the mutual coefficient of induction of two circuits is to be referred to, it will of course be the mutual inductance.

I may perhaps also be allowed to mention, whilst on the subject of nomenclature, a difficulty thrown in the way of learning by the S.T.E. and E., which some time ago had some trouble with its own nomenclature. Having changed name three times, it might be called "The Society of Variable Nomenclature and of the Redundant Conjunction." I should like it to have been called simply "The Electrical Society," following the example of so many other societies who are satisfied with simple and comprehensive names. For instance, the Physical Society does not call itself the Society of Physicists and of Natural Philosophers, nor does the Mathematical Society call itself the Society of Mathematicians and of Arithmeticians or Geometricians. But that is not the point to which I would refer, which is, that the S.T.E. and E. has its journals sewed and wired in such a manner that a real difficulty is placed in the way of getting at their contents. They won't lie open, for one thing, which has been called the unpardonable sin of book; they must therefore be held open; more than that, they must be strongly stretched before the words nearest the wires become readable, as they are nearly hidden by reason of the curvature. It is as exasperating as a tight boot.—Yours, &c., OLIVER HEAVISIDE.

MEASUREMENT OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The author of the paper on the "Calorimetric Measurement of Incandescent Lamps" in your last issue appears to have ignored the two important factors in connection with the amount of heat given off by incandescent lamps, viz., the efficiency at which the lamps are run and the perfection of the vacuum. The latter he of course could not only have determined approximately, but the former was merely a question of calculation, and as the four incandescent lamps tested appear all to have been run at different efficiencies the value of the table given at the end of the paper is thus negatived.—Yours &c., E. S.

INSURANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the inquiry of "Insurance" in your issue of 5th inst., I may mention that this company is prepared to receive proposals for insurance against accidents from electrical engineers. The circumstances in each case are, of course, taken into account, but ordinarily a premium of £6. 5s. provides the following benefits:—

£1,000 in the event of death or permanent total disablement; £500 in the event of permanent partial disablement; £6 per week during temporary total disablement; and £1. 10s. per week during temporary partial disablement.—Yours, &c., J. MOODY STUART

(Fellow of the Institute of Actuaries), Manager

Scottish Economic Life Assurance Society (Limited),
34, King-street, Cheapside, 10th Feb., 1886.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter from "Insurance" which you published in your last issue raises a point which I should be glad to see elucidated, and some practical result obtained in the way of a definite classification from one or more of the accident insurance companies.

My own experience has been as follows:—I insured about four years ago in a well-known company, and I took out a full policy, paying the premium for extra risks. About this there was no difficulty. About a year afterwards I was induced by one of my friends, who has an agency for another company, to

Digitized by Google

transfer my policy to that company. This I did, taking as before a full policy, and paying the premium for medium risks. I have regularly renewed this policy until quite recently, when I was desirous of taking out a policy for a smaller amount, as I considered that the work I was engaged in at the time, and was likely to be engaged in, was much less hazardous than had previously been the case.

I therefore applied to the company for another policy for half the amount of the previous one, and also to know whether they would grant the policy under the "ordinary risks" instead of the "medium risks," and I pointed out why I considered my risks were less than heretofore. Among other things, I stated that my work was largely experimental.

In reply I was informed that I could be insured under ordinary risks if the policy were endorsed to exclude risks from *electrical experiments*. I replied that I did not consider it advisable to take out a policy which did not cover all risks, and I would therefore take out the policy, as heretofore, under "medium risks," but for half the previous amount. In reply, I was informed that they would only grant a policy which excluded risks from *electrical experiments*.

I did not trouble myself to argue the matter with them, but allowed it to drop, as I thought that such ignorance was not worth further argument.

A good deal might be done, however, by concerted action, and I shall be glad to place myself in communication with "Insurance," or any other of your correspondents or readers who wish to take up the matter, with a view to making proper representations to one or more of the Accident Insurance Companies.—Yours, &c., R. I. S. K.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to a letter in your issue of the 6th inst., signed "Insurance," I beg to say that the subject of insuring electrical engineers has received the attention of this company, and it has arranged to place them in the same class of risk as civil engineers. I shall be happy to supply terms on application.

I may add that this company already has amongst its policy-holders electrical engineers connected with some of the best known Electric Lighting Companies in the country.—Yours, &c., A. B. SHELLEY, Secretary.

Imperial Union Accident Assurance Company (Limited), 32, Finsbury-pavement, London, Feb. 11, 1886.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Two letters in your current number need notice. One, the important communication under the signature of "Insurance," if correct, indicates serious error on the part of the accident companies; but an error which has doubtless been fostered by the obstinate refusal of information as to the number and severity of the accidents which have hitherto occurred. At the same time, as a medical insurance officer of over twenty years' experience, I can affirm that the real reason for refusing a risk is not always that alleged by the person declined or his friends.

The second is the renewed howl of Mr. J. Johnstone in favour of his "Electric Boy." To his former ululation I did not reply, because it contained no new facts and was discourteous. "Hamlet" stepped in and at once made the matter clear. I did not venture even to "insinuate" that Mr. J. J. had been humbugged; but "Hamlet" (who had some experience in imponderable matter) seems to do so.

To one statement in Mr. J. Johnstone's second letter I must categorically demur. "If the electricity in the boy's body," he states, "came up from his feet, his legs when touched ought to have given a shock stronger, or as strong as that obtained from his body."

I strongly advise Mr. J. to patent his new source of electricity "inhaled" in breathing; for it is entirely novel, and is a "Thierische Elektricität" of the most startling nature. Only it would be well if he were first to demonstrate its existence.—Yours, &c., WILLIAM H. STONE.

Sanctuary, Westminster, S.W.

THE STEAM ENGINE INDICATOR.—XV.*

BY AMICE.

We may now turn our attention to the compound engine, and should, perhaps, first explain that the engine at present made under this name is old in conception, has been made for many years, but has become a more simple and more economical engine by modern developments. For these developments we have been chiefly indebted to marine engineers, who have by their practice shown that not only can high-pressure be used with an approximately equable turning movement on the crank-shaft, but that the reduction in size of engines obtained by this use of high-pressure is attended with no disadvantages, and the engines are more economical than the simple engine. The compound system has now been developed to the extent of performing the expansion in three cylinders, or by what are known as triple expansion compound engines, and almost all new vessels are being fitted with them. The adoption of the compound system has extended to land engines of almost every kind, and most recently to locomotive engines; and it is especially suitable for electric lighting work, because this work is uniform, and the advantages of the compound engine can only be fully obtained when the work it performs is approximately uniform.

We have already referred to the condensation which takes place in steam engine cylinders as a result of the fall in temperature of the cylinder, due to the fall in pressure during expansion. It is obvious that the condensation due to this cause will be greater as greater ranges of expansion are adopted. The limit to useful expansion in a single cylinder is thus controlled, and therefore the limit to useful high-pressure is also soon reached. For instance, in the case of a simple engine no good purpose can be served by adopting a terminal pressure of less than about three to five lbs. per square inch. On the other hand, the advantages of high ratios of expansion are counterbalanced by the condensation which attends them. The higher limit of pressure will thus be fixed by selecting the most economical range of expansion. If this be, say, six, then allowing for condensation, which is inevitable even at this ratio, and taking into consideration the economical advantage which attends the use of higher pressures in making engines smaller for the same work, and thus taking less steam for moving their own parts, the maximum useful pressure will not exceed from 40 to 50lb. per square inch, except where high pressure is specially useful in reducing the size of the engine.

A comparison of the possible advantages may be better or more readily seen by taking pressures and ratios of expansion, and, for the sake of illustration, making no allowance for losses. Thus a sixfold expansion in a simple engine would, if the terminal pressure be 5lb., need an initial pressure of 30lb. The specific volume of steam at 30lb. (see p. 227), is 881. If now, on the other hand, practical conditions are so altered that we can safely and economically use any range of expansion, the terminal being as before 5lb., and the initial pressure 150lbs. (quite common now), we could use a range of $150 \div 5 = 30$. Now, the specific volume of steam at 150lb. per square inch being 203, one volume of such steam expanded 30 times would give us 6,090 volumes. On the other hand, the 30lb. steam would give $881 \times 6 = 5{,}286$. In practice, however, such a very large ratio of expansion would be impossible, the losses attending the use of the very high-pressure and temperature would be considerable, and five cylinders would be required to perform the expansion even in five-fold stages. With 150lb. steam, a ratio of from 15 to 20 might be used, and with the 30lb. steam not more than 3; so that the economical advantage is still, in spite of practical obstacles, on the side of high-pressure, while the engine for the purpose will weigh less and occupy much less space, a gain which is much greater when the space occupied by the boilers is taken into consideration.

The compound engine, therefore, whether with two, three, or four cylinders in series, is gaining ground rapidly, and for such purposes as electric lighting, driving mill machinery, or as marine engines, will no doubt wholly replace the simple engine. We must, then, consider the application of the indicator to

* For Art. 14, see *The Electrician*, 29th January, 1886.

Digitized by Google

engines of these classes, and then deal with the problems which appear in connection with the several diagrams from the two or more cylinders. In the compound engine with two cylinders in series, the steam from the boiler is first admitted to a smaller cylinder, where the cut-off will be from one-third to, say, one-half the stroke, or the ratio of expansion from 2 to 3. From this cylinder the steam is exhausted, or is allowed to pass into a larger cylinder either with a receiver between the two, or with only the steam valve chest and passages between the two cylinders. The steam is perhaps cut off at from half-stroke to three-fourths in this cylinder, according to its size. The re-relative sizes of the cylinders and the cut-off in both cylinders are arranged so as to obtain as nearly as possible the same amount of power from both. The pressure in the low-pressure or second and larger cylinder is always active as back pressure in the high-pressure cylinder, and thus cutting off in the low-pressure cylinder only tends to increase the back-pressure in the high-pressure cylinder towards the end of its stroke. This may not be harmful, but the amount of this will be determined by the same considerations as those which would determine the most useful amount of compression in a simple engine, and by the amount that may be usefully used when necessary to balance the power of the two cylinders by this means. Assuming the two cylinders to be proportioned exactly to the pressure and work to be done, then the total expansion in a two-cylinder compound engine will be equal to the volume of the low-pressure cylinder divided by the volume of the steam admitted to the high-pressure cylinder to the point of cut-off, and in this case the back-pressure in the high-pressure cylinder will not increase towards the end of the stroke of the low-pressure cylinder, as the cut-off in the low-pressure cylinder will be practically at the end of its stroke.

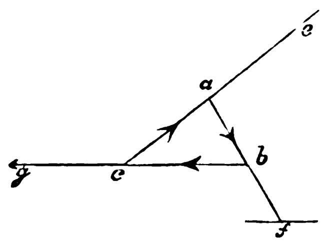
ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 247.)

*Grassmann's Theory.**

The method by which Grassmann obtains his theory is very remarkable. He objects to Ampère's formula for the force between two elements of current, because it makes the force between two parallel elements change from an attraction to a repulsion when the angle which the elements make with the line joining them passes through the value $\cos^{-1} 2/3$, and the object of his investigation is to get a law of force free from this peculiarity, and which, while giving the same result as Ampère's for closed circuits, shall yet be as simple as possible. He begins by regarding any circuit as built up of "winkelströme," *i.e.*, currents flowing along the two infinite lines which form any angle. He points out that a circuit of any shape



can be built up of such currents. The circuit *a b c*, for example, may be regarded as built up of the "winkelströme" *e a f*, *f b g*, and *g c e*. Grassmann proceeds to calculate by Ampère's formula the action of a "winkelstrom" upon an element of current (α). Since the "winkelstrom" will have no action upon an element of current perpendicular to its plane, we see that it is only necessary to calculate its action upon the component (α') of α in its own plane. Grassmann does this by calculating the effect due to each arm of the "winkelstrom" separately. He finds expression for the forces along and perpendicular to α' due to an infinite rectilinear current starting from a definite point. The force of such a current along α' does not depend on the angle the current makes with the line from its end to α', so that the effects of two such currents starting from the same point, and flowing in opposite directions, *i.e.*, of a "winkelstrom," will be to produce no force along α'; thus the effect of a "winkelstrom" on an element of current in its own plane will be a force at right angles to the element. The force at right angles to α' due to a rectilinear current will consist of two parts, one independent of the angle made by the current with the line joining its end to the element, and the other depending upon this angle. The first part will vanish when we consider a "winkelstrom;" the second part only will produce any effect.

Now, Grassmann says that it will much simplify the analysis, and obviously (since any closed circuit may be built up of "winkelströme") lead for closed circuits to the same result as Ampère's formula, if we suppose that the law of force between elements of currents is such that the only effects produced by a rectilinear current are those which do not vanish for a "winkelstrom;" and hence that a straight current exerts on an element of current a force at right angles to the projection of the element on the plane containing the centre of the element and the rectilinear current, and that the magnitude of this force is

$$\frac{i\,j\,ds'}{r}\cot\frac{\alpha}{2}$$

where i is the strength of the rectilinear current, j the strength of the element of current, ds' its projection on the plane through its centre containing the straight current, r the distance of the element from the end of the straight current, and α is the angle which the rectilinear current makes with the line joining its extremity to the elementary current. By taking the difference of two such rectilinear currents, Grassmann finds the action of an element (β) of current on another element (α) is a force at right angles to α', the component of α in the plane containing β, and the middle point of α, and equal to

$$i\,j\frac{d\sigma ds'}{r^2}\sin\theta,$$

where θ is the angle which β makes with r, $d\sigma$ the length of (β), and j the current flowing through it.

The direction of the force is along A B, where A is the centre of the element (α) and B the point where the normal to α' is cut by β, produced *in the direction* of the current.

If we treat this theory in the same way as we did Ampère's, by considering the action of the components α_1 β_1 of an element of current ds_1 on the components α_2 β_2 γ_2 of another element ds_2, we see that Grassmann's theory is equivalent to supposing that α_1 exerts no force on α_2 β_2 or γ_2; that β_1 exerts a force $A\beta_1$ α_2 on α_2 at right angles to α_2 in the plane of *xy*, and a force $A\beta_1$ β_2 on β_2 at right angles to it—that is, along the line joining the element, and that it exerts no force on γ_2. Thus we see that Grassmann's theory is equivalent to replacing Ampère's assumption that the force between two elements of current acts along the line joining them, by the assumption that two elements of current in the same straight line exert no force on each other.

As a dynamical theory of electrodynamics, Grassmann's theory is open to the same objection as Ampère's, that it does not take into account the couples which may exist between the elements, and also to the additional objection that according to it the action of an element of current ds_1 on another element ds_2 is not equal and opposite to the action of ds_2 on ds_1, that the momentum of the two elements ds_1 and ds_2 will not remain constant; and as the theory does not take into account the surrounding ether, there is no way of explaining what has become of the momentum lost or gained by the elements. As a piece of geometrical analysis, however, the theory is very elegant, and worthy of the author of the "Ausdehnungslehre."

From the way in which Grassmann's theory was developed, we see that between closed circuits it must give the same forces as Ampère's; for unclosed circuits this is not the case, and Grassmann, at the end of the paper quoted above, mentioned a case where the two theories would give opposite results, assuming that unclosed streams exist. Suppose we have a magnet Ns, and an unclosed current AB in the same plane as the magnet, and passing through its middle point, then, if

* *Pogg. Ann.*, 64, p. 1, 1845. "Crelle," 83, p. 57.

Digitized by Google

Ampère's theory be true, the magnet will twist in one direction; if Grassmann's, it will twist in the opposite. This depends upon the change, according to Ampère's theory, of the force between two parallel elements, from attraction to repulsion, when they make the angle with the line joining them at less than $\sin^{-1} 1/\sqrt{3}$, while, according to Grassmann's theory, there is no such change.

*Stefan's Theory.**

This resembles Ampère's theory very closely, except that Stefan does not make the assumption that the force between two elements of current is along the line joining them. This difference leads to the introduction of two forces which Ampère neglects. We shall use the same notation as when we discussed Ampère's theory, and consider, as before, the action of an element of current ds_1 on another element ds_2. Stefan, like Ampère, assumes that we may replace an element of current by its components, so that we have to consider the action of the components $(\alpha_1 \beta_1)$ of ds_1, or the components $((\alpha_2 \beta_2 \gamma_2)$ of ds_1.

As in Ampère's theory the component α_1 is supposed to exert a force $\frac{a\,\alpha_1\,\alpha_2}{r^2}$ on α_2, this force by symmetry must be along the line joining the elements; α_1 is supposed to exert a force on β_2 equal to $\frac{c\,\alpha_1\,\beta_2}{r^2}$ along the axis of y.

We can see that this force may exist, for it is conceivable that it should be in the same direction as β_2 when α_1 points from the middle of ds_1 to the middle of ds_2, and in the opposite direction to β_2 when α_1 points in the opposite direction.

Stefan assumes that α_1 exerts no force on β_2 parallel to the axis of z, and no force at all on γ_2.

β_1 is supposed to exert a force on α_2 parallel to the axis of y and equal to $\frac{d}{r^2}\,\beta_1\,\alpha_2$.

We may see by the same reasoning as we used before for the force between β_1 and α_2, that it is conceivable that this force may exist. β_1 is supposed to exert no force on α_2 parallel to the axis of z. As in Ampère's theory β_1 is supposed to exert a force on β_2 equal to $\frac{b}{r^2}\,\beta_1\,\beta_2$, this force must by symmetry be along the line joining the elements; β_1 is supposed to exert no force on γ_2.

Thus the action of ds_1 on ds_2 consists of a force

$$\frac{1}{r^2}\left\{ a\,\alpha_1\,\alpha_2 + b\,\beta_1\,\beta_2 \right\}$$

along the line joining the elements, and a force

$$\frac{1}{r^2}\left\{ c\,\alpha_1\,\beta_2 + d\,\beta_1\,\alpha_2 \right\}$$

at right angles to this line in the plane containing ds_1 and r.

If we take arbitrary co-ordinate axes, and suppose that $x,\ y,\ z$ are co-ordinates of ds_1, $x^1\ y^1\ z^1$ those of ds_2, then the x component of the force on ds_2, due to ds_1, is shown by Stefan to be equal to

$$i\,j\,ds_1\,ds_2 \left\{ m\frac{d_2}{ds^1\,ds_2}\,\frac{(x^1-x)}{r} + n\frac{d}{ds_1}\,\frac{1}{r}\,\frac{dx^1}{ds_2} + p\frac{d}{ds_2}\,\frac{1}{r}\,\frac{dx}{ds_1} + q\,\frac{x^1-x}{r^3}\cos\epsilon \right\}$$

with similar expressions for the force parallel to the axes of y and z.

Here $i,\ j$ are the currents through $ds_1\ ds_2$ respectively, ϵ is the angle between the elements of current and

$$m = -\frac{1}{3}\left\{ a - b - c - d \right\}$$

$$n = \frac{1}{3}\left\{ a - b - c + 2d \right\}$$

$$p = -\frac{1}{3}\left\{ a - b + 2c - d \right\}$$

$$q = \frac{1}{3}\left\{ a + 2b - c - d \right\}$$

We see from this expression for the force parallel to x, that the last term is the only one which does not vanish when integrated round two closed circuits of which ds_1 and ds_2 are elements. So that the force will depend only upon q.

The value of q will depend upon the units we adopt. In Stefan's work q is put equal to $-\frac{1}{2}$. This is the only condition to be got by considering the translatory force between two circuits; we can get another by considering the couple acting on the closed circuit, supposed rigid, of which ds_2 forms a part.

For the Z component N of this couple Stefan finds the expression

$$N = i\,j\,q\iint\frac{y^1x - x^1y}{r^3}\cos\epsilon\,ds_1\,ds_2 - i\,j\,p \iint\frac{1}{r}\left\{ \frac{dx^1}{ds_2}\,\frac{dy}{ds_1} - \frac{dy^1}{ds_2}\,\frac{dx}{ds_1} \right\} ds_1\,ds_2.$$

But supposing the two circuits to have a potential

$$i\,j\iint\frac{\cos\epsilon}{r}\,ds_1\,ds_2$$

we can easily see that the couple

$$= i\,j\iint\frac{y^1\,x - x^1\,y}{r^3}\cos\epsilon\,ds_1\,ds_2 - i\,j\iint\frac{1}{r}\left\{ \frac{dx^1}{ds_2}\frac{dy}{ds_1} - \frac{dy^1}{ds_2}\frac{dx}{ds_1} \right\} ds_1\,ds_2.$$

Thus, if two circuits have a potential

$$p = q,$$

or substituting for p and q their values,

$$2a + b + c - 2d = 0.$$

If $c = 0$ and $d = 0$, as in Ampère's theory, this relation becomes

$$2a + b = 0,$$

which is the same relation as Ampère deduced, by finding the condition that the force due to a closed circuit on an element of current should be at right angles to the element, and Stefan has proved that on his theory the same condition leads to the equation

$$p = q,$$

i.e., the same condition as the one which expresses that two closed circuits have a potential.

Stefan shows that from the consideration of the action of closed circuits on elements of other circuits, or of themselves, it is impossible to get any other relation between the quantities $a,\ b,\ c,\ d$, so that we have only two relations between the quantities $a,\ b,\ c,\ d$, and thus two of them must be indeterminate.

We may give any values we please to these quantities, provided they satisfy these two relations. If we put $c = 0$, $d = 0$, we get Ampère's theory; if $a = 0$, $c = 0$, Grassmann's, and we can get a number of other theories by giving different values to these quantities.

Stefan's theory is open to the same objection as Ampère's, since it does not take into account the couples which one element may produce on another. He also limits the generality of his theory by supposing that the force between two elements of currents in one plane is in that plane.

(To be continued.)

* Stefan, *Wien Sitzungsberichte*, 59, p. 693, 1869.

THE MAXIM-WESTON ELECTRIC COMPANY (LIMITED).—The Directors of this Company give notice that the fifth annual ordinary general meeting of the Company will be held at the Cannon-street Hotel, on Friday, the 19th inst., at two o'clock, to receive from the Directors a report and statement of accounts of the Company for the year ended 31st December, 1885, to elect two Directors and an auditor in room of those who retire by rotation, and to transact the ordinary business of the Company. The Directors, in their report, remind the shareholders that no allowance was made during the past two years for contingencies such as are referred to in Section R of Clause 75 of the articles, and they have now deemed it prudent to pass the sum of £3,606. 5s. to the credit of a general reserve account. After making the above reserve the total balance at credit of profit and loss account, including amount brought forward from previous year, is £5,284. 19s. 8½d. The Directors recommend the payment of 7½ per cent. dividend, which will leave a balance of £597. 9s. 8½d. to be carried forward to next year. The Directors proceed to refer to the reduction of capital by which means the Patents account has been reduced to £35,000. The Directors are happy to be able to report a rapid development of the business, and having now established agencies in nearly every quarter of the globe, which their Patent rights include, are in hopes of showing a larger balance of profit at the end of the current year. The Chairman (Mr. Hugh Watt, M.P.) trusts to be of some service in obtaining the removal of restictive legislative enactments, and is in hopes that the Government will approve of certain amendments to the Acts of 1882, which ought to give a further stimulus to the business.

COMPANIES' MEETINGS & REPORTS.

The Anglo-American Telegraph Company.

The ordinary general half-yearly meeting of the proprietors in this Company was held at the City Terminus Hotel, Cannon-street, on the 15th inst., under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. T. H. Wells) read the notice calling the meeting and the minutes of the last meeting, which were approved and signed by the Chairman as correct. The report was taken as read.

The CHAIRMAN, in moving its adoption, said that when he last addressed them he was obliged to tell them, as was the fact, that several of their cables on the other side of the Atlantic had suspended action. They were aware that quite independently of the cables which carried the traffic of the Company across the Atlantic they had a regular system of cables on the other side connecting those cables with the different seats of traffic in America. Those short cables were nearly all out of order when he last addressed them ; but he had now the pleasure of telling them that they and the whole of the rest of the system were now in perfect order and working with efficiency. There was not a single mile of their plant now that was not in perfect order. That was, of course, a very important consideration, because, no matter what their condition might be in other respects, if their plant was not capable of carrying their traffic they could expect no results from it. He was, however, very sorry to say that he could not give them a very satisfactory account of the traffic itself. The competition still continued. The truth was that the public in their wisdom had put down in the Atlantic such a number of cables that the traffic at present did not afford a living to any of them, and his belief was that a living could not be afforded to any of them without one of two things occurring. One relief might be obtained by a very large increase in the traffic ; but he was very sorry to say that the experience they had had of now nearly twenty years, having tried tariffs of all sorts, high and low, that they could not find that there was that elasticity in the traffic which would enable the number of cables that now existed in the Atlantic to live and make a profit. It was an old saying that they could not take a quart of liquor out of a pint pot, and really that homely phrase illustrated perfectly the condition of things in the Atlantic. It appeared to him that unless a return of prosperity in trade made a great change in the Atlantic traffic, that they had completely exhausted the elasticity of that traffic. The only other alternative was one which the public would not like, but it was one which he had more than once had to declare would be the result of inordinate competition, namely, that the rates must be raised. There was an old saying, that where combination was possible competition was not likely to continue, and with the small number of people whom it was necessary now to bring into agreement in order to raise the rates of Atlantic telegraphy, his belief was that the rates would be raised—raised, as one of his friends suggested to him, to a paying figure. They had been hoping and expecting for some time that that would take place, and he could not help thinking that the time was not far distant when that would be so, and he would give them his reasons for that opinion. The gentlemen who placed the last two cables in the Atlantic were gentlemen of great wealth in America. They all knew that on this side of the Atlantic we were obliged to be satisfied with a very moderate rate of interest on our investments, but that was not the case on the other side of the Atlantic. In the United States they required a much larger rate of interest for their money in order to be satisfied with it than we did here, and he believed that those gentlemen, after the experience they had acquired by the last year's transaction of their business, would not be very much gratified with the return which the large outlay which they had made on those two cables had brought them in, and he believed that that consideration would before long have its weight, and bring them to a state of mind in which they would listen to reasonable terms. At all events, if that were not the case—if events did not take that course—this Company had always the power of drawing the sword. There was a limit to forbearance. They were unwilling to throw away more money in what was called a battle of rates ; but of course if nothing else would do they must come to that at last. He did not mention this by way of threat, but it was a fact that they must all look in the face, and if they had to go into a battle of rates they were in a very good position to carry it on. They had a perfectly efficient system, and, as he had said, the plant was in good condition, and, moreover, they had what he was going to call their old enemy—their very large renewal fund—at the back, which would give them strength in fighting such a contest. Having said so much about the state of the traffic in the Atlantic, he now wished to say a few words about the accounts. Of course it was the duty of their Directors, at a time when the receipts were coming in so slowly, to do their utmost to economise in the administration of their affairs, and he thought if they would compare the accounts of the last half-year with those of the corresponding period of 1884, they would find that economy had been exercised in almost every item. There was a a reduction in almost every item of the accounts, beginning with the expenses at the head office in London, upon which the reduction had been £221 in the year. That did not seem a large sum, but it showed that the Board were working in the direction of diminishing the expenses. They could not expect a very large reduction in the working expenses of one half-year, but the fact he had mentioned showed that they were endeavouring steadily to keep them down. The difference in the expenditure between the two half-years at the stations was £4,800 ; but it was only right to mention that that reduction in the past half-year had been due to the cecessation of some extraordinary expenditure in the previous half-year, which was not a recurring item. There was also another matter to which he desired to call attention. If they looked at the revenue account for the last half-year they would see that the repairs of cables (which of course was the result of the state of things to which he had alluded at the beginning of his remarks) had cost £11,376, consisting of the expenses of their steamship, "Minia," £10,417, and the value of cable expended £958. However, the "Minia" was not engaged in repairing the Company's cables the whole half year, and they chartered her to other companies, and obtained £10,270 in that way. Therefore their Company had their repairs last half year effected for very little more than the cost of the cable expended in carrying out the operation. That he thought showed that the Board were getting in every penny they could in every direction, and trying to keep down expenditure in every possible way. With respect to the old subject of debate in that room—namely, the renewal fund, probably they would have seen in the papers an account of a meeting of stockholders in reference to that matter. Those gentlemen met two or three weeks ago and appointed a committee, who asked to have an interview with the Directors. Within the last year a very important constitutional question had been settled, as it was called out of doors, by a meeting between the members of the Ministerial party and those in Oppositon, and they on that Board were not at all above adopting so good a precedent whenever they saw it occur, and they at once acceded to the request of the gentlemen of the committee that they should have an interview with the Directors. They would remember he had told them—he believed it was at the last half-yearly meeting—that the Board had determined to reduce the contribution to the renewal fund, owing to considerations which they had themselves formed, from £150,000 to £100,000 a year. That arrangement, it was decided, was to continue for three years, after which the contribution was to be further reduced. After a conference with the committee, however, at the beginning of this week, they had come to the decision that as soon as the renewal fund had reached the sum of one million, they would put no further accretion to it from the revenue, and that the only sum that should be added to it after that period should be the interest on the renewal fund itself. That resolution was accepted by the committee as satisfactory. The resolution of the Board, he ought to say, was conditional on no break-down taking place within the next year, because if any of the cables gave out they would have to replace them, and to reconsider their decision. He might, for better certainty, read the minute of what took place between the committee and the Board at the conference to which he had alluded. "The Anglo-American Telegraph Company, 2nd February, 1886. Having had a conference with a committee of shareholders with respect to the renewal fund, the Chairman stated that in the circumstances in which the Company is now placed by competition, &c., the Directors would stop further contributions from revenue to the renewal fund when that fund should amount to one million. After that date the interest alone would be added to the principal. This decision is upon the assumption that no serious disaster to the cables occurs before one million is reached. What is to be done if the fund falls below one million is left to the future decision of the Directors." That was the way the matter now stood. Mr. Smith, of York, who led the opposition to the renewal fund on former occasions, had expressed himself satisfied with the decision of the Directors, and had authorised him (the Chairman) to say that he would not put the resolution of which he had given notice in the circular which he had sent to the shareholders. He had also received a letter from Mr. Smith on the previous night, in which, in addition to what he (the Chairman) had said, Mr. Smith wished that the Directors should give an engagement that no sum beyond £100,000 should be expended from the renewal fund without the sanction of a meeting of the proprietors. That, however, involved—he was almost afraid to say it—an infraction of the Articles of Association [laughter] [A Voice : "Which we want altered"]. Mr. Smith's object could not be carried into effect without an alteration of those articles. Would they allow him in all good faith and kindliness of feeling to ask what necessity there was for such an alteration? What had been the history of the renewal fund? The object of such a proposition as that of Mr. Smith, they could, of course, all see—and it was a very just and natural object—was to prevent any expenditure of the renewal fund on anything except that for which it had been put by—that was to say, the renewal or replacement of the cables already in existence. What, however, had been the history of the Company? When he first became connected with it they had the 1865 cable and the 1866 cable and the French cable, of which he was the original Chairman. Immediately after the junction between the Anglo-American and the French Companies they laid another cable with the material which had been provided by the first French Company for duplicating their own cable. Immediately after the junction of the two companies they began accumulating the renewal fund. Therefore, none of the cables laid before that period could have been laid in any other way, or paid for in any way out of the proceeds of the renewal fund. What subsequently took place? The 1865 cable gave out, and by the terms of their agreement with their allies in the pooling transaction they were bound to replace that cable by another one. Fortunately, they had a considerable quantity of material which was to have been laid by the French Company in duplicating their cable, but the cable they put down from Ireland to Newfoundland was not nearly as long as that for which they had made provision, and therefore that large amount of material was available for laying the new cable of 1874. That cable was laid partly out of the French Company's material and partly out of the renewal fund. Therefore the only expenditure which the fund had made up to this time was in repairing (and repairs were replacements) some of the cables and assisting in laying the 1874 one. Afterwards the 1866 cable gave out, and they found it impossible to repair it, and they laid, exclusively out of the renewal fund, a new one in its place. They would all admit that the renewal fund was intended to replace the property and everything else as it gave out. He had shown them that up to this time they had never spent anything from that fund for any other purpose, and what right had they to assume that the

Digitized by Google

Directors would do in future what in the past they had never thought of doing? Mr. Smith, in his letter, had spoken in very kind and flattering terms of the present Board, and left it to be inferred that if the present Directors were immortal he would not require such a change in the Articles of Association. But all he (the Chairman) could say was that when the present Directors passed away and another Board succeeded them, if they were not so scrupulous as the existing Board about the renewal fund, his belief was that any shareholder could obtain an injunction to prevent them from applying it to any other purpose than that for which it might be legitimately applied. The very name of the fund, he considered, would prevent them from spending it for any purpose except that of renewals or replacements. That was its object—the object for which it was created, and the only one in his belief to which it could be legally applied. That being so, why change the Articles of Association, discrediting the Directors—for it came to that—and bringing discredit on the whole enterprise itself when there was no reason, from what had occurred or was likely to occur, for making the change? Those were the reasons why he could not accept Mr. Smith's proposition, and the Board having maturely considered the subject, adhered to that view. He hoped that they would agree to go on as they had done. The shareholders had the most complete guarantee that he could conceive for the security of that fund, in which they had, in his opinion, a backbone which would support them through the disastrous events which might, but which he hoped would not, occur in the history of their enterprise. He concluded by moving the following resolution:—

"That the report of the Directors, dated 28th January, 1886, and the accompanying statement of accounts to the 31st December, 1885, and submitted to this meeting, be and the same are hereby received and adopted; and that the following dividends, less income-tax, be now declared—that is to say, first, a balance dividend of 10s. per cent. upon the ordinary consolidated stock for the year ended 31st December, 1885, making, with the previous payments, 1¼ per cent. on that stock for the year 1885; second, a balance dividend of 1 per cent. on the preferred stock for the year ended 31st December, 1885, making, with the previous payments, 2½ per cent. on that stock for the year 1885."

The Marquis of Tweeddale seconded the motion.

Mr. Chester desired to know the expenses and the earnings of the "Minia" for the whole of the past year, the chairman having given the result for the past half year.

Mr. Thos. Smith (of York) thought they might congratulate themselves that they had now seen an end to the additions to the renewal fund as from the 31st December of the present year, when they would have the full use of their net earnings. His lordship had made a slight mistake. The arrangement come to by the Directors and the committee was that at the end of the present year additions to the renewal fund should be allowed to be made only from the interest earned by the fund. The fund at the end of the present year would be short by only £18,000 or £20,000 of £1,000,000, and after that no further additions would be made to it except out of interest. He trusted that the shareholders would accept that arrangement with satisfaction as practically closing the drain on their resources, and also leaving them for future contingencies the immense sum of a million. That was a large sum, and was a grand backbone for all contingencies. They had now only to guard against its expenditure. They all heard what his lordship had said on that matter. He rather differed from his lordship; but still as they had educated him up to their views so far, perhaps they might leave Viscount Monck, and see whether, like all good Liberals, he would not advance still further. He need not say that, as a holder of all the stocks in the Company, he had been acting simply in their interests [A Voice: "And your own"], and his own of course. He had not sold any of his stock. The Directors having now made what he considered a satisfactory settlement as to any further additions to the renewal fund, he had much pleasure in taking a course which he had never done before. That was to support the adoption of the report before them. He might also say, however, in doing so, that he did not undertake to blindly follow the Directors in whatever they might propose in the future. As in the past, he intended to reserve, as a man of business, the right to act upon his own independent judgment in all matters concerning the future management of the affairs of the Company. He might state that they received a very courteous reception from the Directors at their interview. The discussions in the past respecting the renewal fund might have involved some waste of time; but after all, he did not think there had been waste of time seeing that they had got the Directors to accept their views to the extent mentioned.

Mr. Chipperfield asked the cost of the last cable laid by the Company?

The Managing Director (Mr. H. Weaver): Something over £400,000.

Mr. Chipperfield inquired whether the Directors knew how much the Mackay-Bennett cables had cost.

The Managing Director replied in the negative.

Mr. Chipperfield, continuing, said that what he desired to draw attention to was that when the renewal fund was first started the cost of laying a cable was very much larger than that of such a work now, and in view of this fact he wished to know whether it was necessary to allow the fund to grow to such a large extent. He had just been told that the last cable had cost the Company only £400,000.

The Managing Director observed that that was the actual money spent on the cable, but beyond that they had the old shore ends which they could use.

Mr. Chipperfield said that what he wished to point out was that if a cable had to be laid across the Atlantic now it would not cost more than £400,000.

The Managing Director replied that it would.

Mr. Chipperfield thought that they might take it that it would not cost more than £400,000, and he wished to know whether there was any necessity for allowing such a large sum to accrue as would be sufficient to lay two if not three cables across the Atlantic.

A Shareholder said they were very glad that the arrangement referred to had been come to between the committee and the Directors, and thought that any money which the committee were out of pocket should be made good to them.

Mr. Smith remarked that the action taken by the committee had been merely for the benefit of the whole Company.

Mr. Garner desired to protest against what the Chairman had said as to engaging in another war. He considered that their Company had nothing to do with other companies in any way. What they ought to do was to charge a reasonable and fair price, and then allow other companies if they liked to enter into competition. Had they done that in the past he maintained that they would have had a monopoly of the working in their own hands.

The Managing Director: You would have had no dividends.

Mr. Garner stated that he maintained, notwithstanding what the Chairman had said, that the proprietors had no guarantee that the renewal fund would be properly spent except the guarantee which they had in the character of the Board. They could spend the fund as they pleased, and they could have a new cable if they liked to-morrow. There was nothing to prevent them from doing that except their honour.

Mr. Chester regretted the remark made by the Chairman in his opening speech, that he believed the elasticity in the traffic across the Atlantic had reached its summit, and that he did not hope for any further elasticity.

The Chairman observed that he had qualified that remark by saying that any improvement in the state of trade might give them an increased traffic.

Mr. Chester believed that telegraghy across the Atlantic was still in its infancy, and that there was a very great expansion for it. They were now at the tail end of three years of the greatest depression that the financial world had ever seen, and he thought that when once they turned the corner (and he believed that it would be turned before long) they would see that telegraphy across the Atlantic would expand ve.y much more than they imagined at present. He was very sorry to hear that the result of the deliberations of the Board had led them to come to the conclusion that they would either possibly have to raise rates or fight. The Directors could not put their feet down on the expansion of the civilisation of the world, and if they thought they could stop telegraphic communication by fighting with other companies, the result would be as it had been hitherto. Every cable that had been laid they fought against and tried to cripple, and finally they had had to buy it up, and the result had been that another cable had been laid directly afterwards. They had been told that the renewal fund could not be used according to the Articles of Association, for any other purpose than that of a renewal fund. But he believed the articles would allow the Directors to enter into negotiations for the purchase of the last two cables which had been put down whenever they liked. If he were in error in that view he would be glad to be corrected. He thought the shareholders who spoke and voted at meetings should stay behind and record their votes when a poll was taken, which was not done on the last occasion. They had seen the determined stand which the Chairman had made with regard to the renewal fund. But what had they found? A body of gentleman had got dissatisfied, a small committee had been organised, they had got round them the nucleus of support, and the moment the Board saw an organised opposition to their policy, which had been so lauded, the Board had given in.

Mr Stockdale said he was very glad to be able to congratulate the Chairman on the striking contrast in the tone of the present meeting compared with that held for the last three half-years, and he thought the change might be attributed to the interview which the Board had courteously granted to the committee. He was pleased to be in a position to say that after a discussion of some two hours' duration by mutual concession they all arrived at a satisfactory understanding [A Voice: "We have heard all this"], and he trusted the shareholders would be satisfied with the result of the committee's alteration with respect to the renewal fund. With regard to that fund, they thought that the shareholders ought to have a voice in the control of such a large sum, for, as was stated by a very eminent legal gentleman at the former meeting, under the present Articles of Association the shareholders had no power whatever. In fact, he did not wish to say it in any offensive sense to the Board, but the Articles of Association virtually placed the shareholders in the category of infants or felons, inasmuch as these articles gave them no power or control over their property. He hoped the Board would see their way clear without being opposed and without any agitation to grant this very moderate concession to the shareholders, who, he was sure, would be only too ready to give the Board power to appropriate to proper purposes part or the whole of the renewal fund. That was what was done in all railway and large companies—the shareholders were first appealed to. He might state that if they had had to go to a poll the committee were prepared to offer very strong and substantial opposition by the amount of proxies which they had received.

Mr. Davison said that they had it on record that the Company required four cables to keep up its engagements with other companies. They also knew on very good authority that the life of a cable was from twenty to thirty years. They had it, moreover, on the authority of their excellent Chairman, that the cost of a cable was about £400,000, and it therefore required very little calculation to see that they would want to renew a cable every 7½ years on the average. Very little consideration would show that the sum of £44,000 per annum, with the increment of compound interest, would produce a sufficient sum to provide £400,000 every 7½ years. They had hitherto put aside something like £180,000 per annum to the renewal fund. The permanent increment of that fund was now stopped, and they would observe that if it were fairly invested it would realise a sum beyond what he had stated. They might fairly assume

Digitized by Google

that the renewal fund, if properly invested, would realise about £50,000 per annum.

The CHAIRMAN: That is at 5 per cent.

Mr. DAVISON thought they would therefore see that if the renewal fund were now stopped at a million and interest on that sum were added, with possibly a slight contribution from revenue if necessary, it would be ample to keep up the cables in future. He congratulated the Directors and the Chairman on having come to the decision which had been indicated.

Mr. JOHN NEWTON said he would not trouble the meeting with improper statistics based on erroneous assumptions as the last speaker had. With regard to the life of a cable, the cables which were now being laid were altogether different from those which had originally been put down, and their life could not be estimated. At a former meeting the Chairman of another company had said ten years ago that the life of a cable was ten years. But those cables were still going on working efficiently. The cost of a cable was not £400,000, but a good deal more. [The CHAIRMAN: Hear, hear.] From Ireland to Newfoundland perhaps a cable could be laid for £400,000, if the manufacturer made no profit out of it. He, however, rose mainly to thank Mr. Smith and the members of the committee for what they had done. They had established this fact, that notwithstanding the abominable system of proxies, the shareholders had some power, and if they could indicate wise and sensible views as to the manner in which their property should be conducted, those views would prevail, notwithstanding that the Directors had their Articles of Association, and could fortify themselves by taking the opinion of eminent counsel, who, of course, would tell them that what they wanted to do they could do in the manner in which the case would be submitted. Those articles, he contended, required alteration, for they were most unfair to the shareholders.

Mr. JACKSON desired to support entirely the remarks of Mr. Smith upon the adoption of the report. He wished first, however, to draw attention to, and acknowledge the benefit which the Company had derived from the exertions of their able general manager at the last International Telegraph Convention at Berlin. The result of these international conferences might be a very serious matter to the Cable Companies, and Mr. Pender, at the late meeting of the Eastern Company, pointed out that that company, by the action of the last Conference, had had to submit to a sacrifice oi £40,000 a year. No such action, however, had been taken in the case ef the Atlantic cables, and he thought they were very much indebted to the Board for obtaining that important concession. For the next five years they would have an opportunity of developing whatever traffic there might be in the Atlantic. He was glad to hear Mr. Chester's remarks with regard to the question of the elasticity of that traffic. Someone had said that the committee ought to be remunerated out of the funds of the Company, but he did not think that that ought to be done. Moreover, the committee had not yet done their work. The question that any expenditure of their vast renewal fund should come before the general body of proprietors would not be dropped. With respect to the Articles of Association, they were drawn up by Mr. Burt for a company in a very different position—for a few capitalists who subscribed a very large amount; and he believed that the same able gentleman would, if he had instructions, be able to carry out such alterations in the articles as would meet the reasonable views of the shareholders.

Mr. PARKER said that the Chairman had referred to the renewal fund as forming a backbone, and he had evidently used the expression not merely as indicating the fact that the possession of that fund would enable them to renew their cables if necessary, but that it might be used also for competing with other companies. It seemed to him that there had been a practical admission that an alteration was required in the Articles of Association, and that the policy of the Board had been of a very doubtful character in buying off competition, as they had done in the past.

MR. GRIFFITH said that the case presented by the committee to the Directors was so strong that he thought the latter had acted wisely in conceding the point mentioned, which was certainly of great importance. He maintained that a million was more than enough for their necessities, and so far he agreed with the remarks of Mr. Davidson, that even if £45,000 were now put by by the accretions of interest, that that would be sufficient for their purpose. He thought that there was great force in the demand which had been made for altering the Articles of Association, and that it would be for the benefit of the Company if they had more unity in the future, and if the Board would allow that the shareholders ought to have a voice in the disposition of the renewal fund.

The CHAIRMAN, in reply, said that with regard to the investment of the renewal fund, it was not the fact, as one gentleman had appeared to suppose, that it was invested in the names of any of the Board. The securities were in the name of the Company, and could only be altered or changed by a resolution of the Board under the seal of the Company. A false construction had been put upon his remarks by Mr. Parker. That gentleman had talked of his having spoken of the renewal fund as the backbone of the Company in the event of a contest. He (the Chairman) had merely meant, when they had a renewal fund which could replace all their plant, that they could feel at perfect ease as to any income that might accrue in using it for competition. He never meant to imply that the renewal fund should be used directly in any contest; and he believed it would be a gross malversation if it were so used. Some observations had been made as to the cost of laying a cable. Mr. Weaver was appealed to, but he (the Chairman) did not think that what that gentleman said was perfectly heard by the meeting. The fact was, that the last cable laid cost the Company in money £430,000, but in addition to that they had the shore ends of the old cable to make use of, and very probably those shore ends, if they had had to replace them, would have brought the cost of the cable up to £500,000. That, therefore, was the cost of a cable according to the most recent experience they had had. Mr. Chester had asked what were the costs and what were the receipts for the whole year of the steamship "Minia." He had given them that information for the last half-year, but for the whole year the total cost of the vessel was £26,228. She was chartered by other companies during the year, and in that way earned £16,430, leaving a balance of £9,798, which represented the whole of the cost of the repairs during the year—he meant as far as the ship was concerned. For that balance they had done the whole of their repairs during the twelve months. There had been a great deal of discussion, but it had been all of such an amicable nature that he did not think it necessary for him to trouble the meeting with any further observations. He then put the motion, and it was carried unanimously.

On the motion of Sir DANIEL GOOCH, Bart., seconded by the Marquis of TWEEDDALE, Lord Monck was re-elected to his seat at the Board, as was also Mr. Wm. Barber on the motion of the CHAIRMAN, seconded by Sir DANIEL GOOCH.

Mr. SEELY proposed, and Mr. JACKSON seconded, the re-election of the auditors, Mr. Joshua Dean and Mr. Francis Glass.

Mr. NEWTON next proposed, and Mr. SEELY seconded, a vote of thanks to Mr. Thos. Smith for his exertions on behalf of the shareholders, Mr. Newton remarking that that gentleman was a very large holder of the stocks, and deserved the thanks of the shareholders for what he had done, as did also the members of the committee.

The CHAIRMAN put the motion, which was carried.

Mr. SMITH having briefly returned thanks for the compliment paid to him,

Mr. JACKSON proposed a vote of thanks to the Chairman and his colleagues.

Mr. GRIFFITH seconded the motion, which was carried, and

The CHAIRMAN having acknowledged the vote, the proceedings terminated.

Anglo-American Brush Electric Light Corporation (Limited).

The fifth ordinary general meeting of their Corporation was held at the Cannon-street Hotel on Wednesday, the 10th inst., under the presidency of Lord Thurlow.

The SECRETARY (Mr. Emile Garcke) read the notice calling the meeting.

The CHAIRMAN then moved the adoption of the report and accounts, and in the course of his remarks said: I desire to congratulate you, and congratulate you heartily, on the improved aspect of affairs which enables us to come before you to-day recommending, it is true a small, but an honestly earned dividend for the past year. I think that this is a source of congratulation, not on account of the amount of the dividend, whether it is large or small, but on account of the fact, as when Directors as a Board feel themselves justified in declaring a dividend, you may, as a rule, be pretty sure that the business of their company is on a satisfactory footing. I can assure you that the position that we have thus been restored to has not been attained without considerable anxiety both on the part of this Board and of the hard-working members of our staff. I may say that if we have attained that position it is mainly due, I think, to the strenuous exertions which have seconded our endeavours, and to the able assistance we have received from the gentlemen who compose our technical and permanent staff. In saying that there is one thing that I must not forget to add, and that is that I consider that the fact of our having returned to a dividend-paying position is due in the first place and in the last place to the unremitting confidence with which we have been treated by our shareholders. You now have had the patience to put your faith in us without receiving any rewards for the past three years, and I assure you I feel very much, as far as I am concerned, that we owe you a hearty vote of thanks for the confidence you have shown in us, without which it would have been perfectly impossible for us to have carried on. The result is that we have turned the corner, and that the affairs of the Corporation now rest not only on a satisfactory, but I believe on a very strong foundation. The works in Belvedere-road have been fully employed with the execution of good orders during the whole of the past year. The volume of work that we have executed during 1885 exceeded that which we did during 1884 by about 25 per cent. The net profits bear as nearly as possible the same relation to each other—those earned in 1885 and those earned in 1884—and those earned in 1885 would have been very much larger had it not been for, I may say, the extravagance of our predecessors, and the fact of our being hampered with an establishment and with premises that are still far beyond our manufacturing requirements. This is an evil which is being remedied, and which can only be remedied in the present by the increasing volume of business, for we have considered the matter from every point of view, and we do not see how we can either profitably reduce our expenses or our establishment in the face of the business which is now growing up. I should add that we have on hand a large number of genuine, sound, and paying orders, which we are now executing, and which will carry us on for almost the whole of the twelve months without any other order. These orders are received from the Government for various colonial departments, for manufacturing firms in England, and for lighting the impending exhibitions which are going to be held in London, Liverpool, Edinburgh, and I think I may add in Folkestone. This is so far a highly satisfactory state of things; but I assure you that we are not contented, and we are doing our utmost from day to day to acquire more orders. But there is this satisfactory feature about our position, and it is a feature which has never changed during the past year, that these orders do come in with regularity. Whether they come in from one quarter or another they come surely enough, and our

Digitized by Google

establishment, of on the average 300 men, has been fully employed, and often employed on overtime during the past year. I desire also to take this opportunity of tendering my thanks to those 300 men for the very great intelligence, energy, and zeal which they have displayed in our service. They have worked for us without a murmur at overtime, frequently on holidays, bank holidays, and others, and during the past year we have not had a single complaint of any serious character against any one of our members. I do not propose to enlarge on the accounts, but there is one little item there that I do desire to refer to—it is the cash at the bank. It appears in the balance-sheet at £6,593. That, of course, is a statement which represents our actual cash balance at the 31st December last, after all our transrctions were squared up. But I desire to assure you that that is not all the capital that we have got to come upon. Far from it. We have, as you will see in another place, £33,000 of good debts owing to us from our various customers, against £20,000 or so due to us at this time last year. That alone shows an improvement of more than 50 per cent. Then our debts are on a moderate scale, they are slightly in excess of what they were last year, but not more so than is fairly represented by the increased volume of business and the necessity of our having a large supply of materials on hand. You are all aware that from time to to time in the newspapers you see that your shares have fluctuated. They have gone down or up. There is absolutely no reason for these fluctuations, and that is one of the reasons why they are one of the greatest trials that a Board like this has to deal with. They encourage false hopes, and they create false despondency. People who have perhaps nothing else to guide them by see the shares go down and sell without rhyme or reason, whereas these fluctuations, as you here all know, are the result of certain clever manipulations of people acting for their own ends. They, however, bear no relation to the state of things that exists at the time. Remember that your shares are worth the money at which they now stand at par, and if you take my advice never part with them for less. There is another matter in this report which is eminently satisfactory, viz., that the public installations that we have run during the past year have been a source of profit and not a source of loss, as in preceding years. These installations, as you know, are at Charing Cross, what is called the City circuit, some lighting we have undertaken at Bristol and Cardiff, and also at Manchester, and one or two other small installations. In 1883 these installations caused us a debit altogether in our accounts of £642. In 1884 they caused us a loss of £268, but this year we have actually derived from them a net profit, which I will not exactly name as these accounts are not all finally closed, but it is a respectable profit, which may be written in three good figures. That, I think, is a matter for congratulation. There is one other point of importance to us all about which I desire to take you into the full confidence of the Board. He then referred to the Bill promoted by the South Eastern Railway Company for an extension of their line, so designed as to cut off a portion of the Company's works, at which point the South Eastern Railway Company propose to widen their line. This, his lordship explained, would involve a considerable sacrifice on the part of the Company, and entitle them to considerable and substantial compensation, for even if what remain of their works would meet with their requirements, they would have to remodel the office, and be put to heavy loss and expenditure of he did not know how many pounds. They had protested against that conduct on the part of the railway company, and from time to time had filed petitions in Parliament, and they were about to do so again, as the railway company had applied for a further extension of time, during which to hold this sword over the heads of the shareholders. The railway company were playing a waiting game, but it would be unfortunate for them, as the company was now paying a dividend, a position which would obtain for them greater indemnification; so that so far nothing had been lost by the time that had elapsed. Continuing, he said: There is another point of very great importance touched on briefly in the report. It is what is called the City lighting. For over a year—I think for nearly two years—we have been in communication with the authorities in the City for arranging a considerable circuit of electric lighting. That has been a very complicated matter, but I hope that the negotiations are now approaching a satisfactory termination. Still, it is a subject of considerable anxiety and importance, because the moment this contract is signed we shall have to find a very large sum of money—a heavy capital sum for laying down these mains and preparing to execute this traffic. We shall have to find the money, and we shall have no difficulty when the time comes in doing so. But I desire to assure you with respect to this matter that we are not rushing into it blindfold, and that we shall only agree to it on three conditions. First, that it is on a paying basis as regards price; second, that it is for a term of years of some duration; and third, that we are to have the right of laying mains of sufficient size to supply customers on both sides, and that the mains are to remain continuous even should the City lighting contract be interrupted. This matter is still under consideration, and is receiving our close attention. Next in order of important subjects comes our foreign business. You are aware that the Continent is more favourably situated as regards electric lighting and all matters concerning electricity than we are. They have no Electric Lighting Act of 1882. They have no repressive legislation, but they are only subject to the common laws of the land. We have been doing a considerable business in Germany for the last eighteen months. About that time a Mr. Plewe came over here with excellent recommendations to us. We entered into communication with him and made a contract with him to supply him at certain rates. We have supplied him ever since with very large numbers of dynamos and large quantities of electrical apparatus, and he has given payment in bills for very large sums which have been met to the day. I am bound to say that the conduct we have met with from Mr. Plewe and the syndicate of bankers who have associated themselves with him in Berlin has been of the most satisfactory character to us. Last autumn they approached us again. They desired to enter into still closer relations with us and to enter into still more extensive business. The proposals they made were so important that it was deemed advisable that Mr. Wynne, the then general manager, and I should go over to Berlin and make further inquiries. We went over to Berlin, and we were received with the utmost courtesy by those gentlemen. They explained the great scheme they had, which I am bound to say seemed to be fully participated in by the public. I made inquiries from eminent banking houses there, and found that there was no difficulty in getting capital to any extent in Berlin for electric lighting. The result of the inquiries I made and the negotiations we conducted were eminently gratifying, and ended in the signing of a sort of treaty by which we have in the first place undertaken to establish the plant for a central lighting station in one of the most commercial and busy quarters of the town of Berlin. This is now being carried out, and I have no doubt it will be the forerunner of very large schemes of lighting, not only in Berlin, but in Dresden, Hamburg, and in other places in which this energetic Mr. Plewe and the syndicate of bankers are preparing the ground for us. It is curious to see on the Continent how differently matters connected with electricity are regarded from what they are in this country. There they are looked upon no longer as being in the initiatory stage, but as having attained to something like perfection. People are no longer hesitating about going in for electric lighting, but are doing that, and demanding electric power besides. People in London would hardly credit the march of electrical science in Berlin. The tramcars there even are already constantly run by means of electricity, and there is now a company formed to take over the whole of the tramcars in Berlin, to abolish horses, and run them with electrical motors at a profit of about fourfold of what the companies are making with horses, and charging at the same time about half the fares which are now being charged. I now come to the troublesome matter of amending the Electrical Act of 1882, of which we have had quite enough. You, perhaps, will remember the steps we took in that direction in the autumn of last year—even the summer of last year. We formed, with other gentlemen interested in this science, a very powerful committee. We were fortunate in obtaining the cooperation of the most distinguished men, like Sir William Thomson, Sir Frederick Abel, Sir Frederick Bramwell (who has rendered us the greatest assistance), Prof. Silvanus Thompson, Prof. Ayrton, Viscount Anson, Mr. Forbes, and a dozen more, and we met from time to time in your office at Belvedere-road, and with the assistance of high legal authorities, who gave us the benefit of their advice and professional knowledge with the utmost courtesy, and without any remuneration, we drafted a Bill to amend the Electric Lighting Act of 1882. That Bill was to have been brought before Parliament by one of us, but it appeared afterwards better to have it introduced into Parliament by some gentleman who was above suspicion as being unconnected with electric lighting, or the electrical industry whatever. Sir Frederick Bramwell here again came to our assistance, and he succeeded, I am bound to say without much difficulty, and I rejoice at the fact, in obtaining a promise from Lord Rayleigh, who ranks second to none in scientific knowledge in England, and I think in the world. He has kindly undertaken to introduce our Bill, or a Bill based on its provisions and identically the same. He is only waiting now till Parliament meets on the 18th or 20th of this month to introduce it. The broad principles on which that Bill proceeds are simply to place electric lighting on the same footing as gas. To effect that, there are really only two clauses of that Bill of 1882 which will need repeal. The first is what is known as the lamp clause—Clause 18, I think—under which the undertakers are prohibited from prescribing the form of lamp to be used in connection with an installation. In the absence of any correct meter, it is imperative to grant us that condition, for how can we tell but what the persons using the electric light might use lamps which would consume more electricity than they had contracted to pay for? Moreover, we have the excellent precedent before us of the Gas Works Clauses Act of 1845, when gas was in its infancy, and Clauses 18 to 20 in that Act gave the power to gas companies in the absence of a meter to prescribe the form of lamp which should be used. That we should be entitled to do the same is an act of fairness which Parliament will not refuse. Then there is another famous clause, No. 27 of the Act of 1882. As that one is sufficiently known I need not dilate upon it. It enables a local authority to buy out an undertaking for the supply of electricity at the expiration of 21 years practically at the price of old iron, and without taking into calculation either the profit, the goodwill, or any conditions which enter so largely into the value of a property. It is not too much to say that Clause 27 as it stands is perfectly prohibitory of electric lighting, for who will subscribe capital when they know of the existence of this clause? And even if you got the capital subscribed, how could you get the customers to pay such a prohibitive rate as would be necessary to recoup the promoters in 21 years? I have no doubt that that clause will be found cut out in the Bill that will pass Parliament. The late Government that has just gone out of office had proposed to deal with this question. Mr. Stanhope, who was President of the Board of Trade (I heard this unofficially), had proposed to bring in a Bill to prolong the period from 21 years, I am informed, to 40 years. No doubt half a loaf is better than no bread, and we should rather have it 40 than 21 years. But as the gas industry was never subjected to any of these restrictive measures at the outset, why should we? And arguing on that basis I protest that any limitation of the kind is an injury and an injustice. I have no doubt that the Bill, as drafted now by us and as submitted to Parliament by Lord Rayleigh, will shortly be introduced; and as I have said before, the justice of Parliament will insist on its being the law of the land. His lordship then referred to the number of unemployed men who were anxious to work, and ventured to say that no more easy and no more efficient relief works could be supplied than by simply amending the Act of 1882, as it would open the door to the immediate establishment of a new and a very extensive industry, involving the lifting of every street in London to lay the elec-

Digitized by Google

trical mains from which every house in London would in due course demand to be supplied. There was abundance of capital waiting to be invested, which would only be too readily embarked in the enterprise. He regretted that since the last meeting Mr. Ladd, one of the Directors, had died. They had also lost the services of Mr. Courtenay, from whom they had received constant and valuable assistance, and that gentleman had only left them because he had to devote himself to another branch of electrical science, the Storage Company, which of late had been making such giant strides as to call for more continual labour from its managing director, a position held by Mr. Courtenay. To fill the vacant seats two gentlemen had been elected who were most favourably known in connection with electrical science—Lord Sudeley and Major-General Webber of the Royal Engineers. These gentlemen were rendering the Company most valuable assistance. Major-General Webber had placed them under a further obligation by accepting the office of managing director, an appointment which had become necessary by the resolution the Board had arrived at to have the services of Mr. Wynne henceforth exclusively devoted to superintending the foreign business of the Company, a position for which that gentleman was well qualified, owing to his long residence abroad, and his intimate acquaintance with foreign languages. He concluded by moving the resolution.

The VICE-CHAIRMAN (Mr. J. S. Sellon): The explicit manner in which Lord Thurlow has referred to the present position and prospects of the Corporation, as well as to the other matters of general interest in connection with the important undertaking in which we are engaged, necessitates but few words from me in seconding this resolution. On former occasions I have had the honour of pointing out to you that by virtue of its patents and the vast field of work which can be covered by its manufactures, the Corporation had an exceptional position. Whatever class of work is needed—I would rather say whatever class of machine is required—whether for high or low tension, whether for isolated and closely localised installations, or for work extending over a distance of many miles, whether for motive power or electro-chemical purposes, the patents you possess are without doubt the most comprehensive, and the apparatus which can be manufactured under them the most nearly approaching perfection of any known system. This being so, you may perhaps ask why more speedy progress has not been made in securing a practical result from this possession—a practical result of earning large dividends. Well, gentlemen, Rome was not built in a day, and the development of a new industry of such a nature cannot, and possibly had better not, be too rapid. Solid foundations are needed for good and durable work, and in the case of this special and as yet little known branch of practical science public confidence has to be won, the prejudice and opposition of vested interests have to be contended against, and the adaptability and advantages of any such new departure have to be still proved. I believe I am right in saying that nearly seventeen years elapsed after the introduction of gas before any gas undertaking was a financial success. I do not think we need anticipate 17 years in the case of electric lighting, for events move more quickly in these days; and though the electric light starts with gas in full possession of the field against it, and surrounded by difficulties which I believe surrounded but few industries, yet I think if we take seven instead of 17 years as the necessary probationary period for electricity to prove its superiority over its great rival, we should not be far from the mark. Nearly six years have now elapsed since it may be considered the first street was electrically lighted, and I may incidentally mention that to this Company belongs the credit of having been the pioneer of electric lighting. As the Chairman mentioned, the authorities of the City of London have, we hope with wise consideration, shown signs of giving in this direction the encouragement and facilities which lie within their power despite any Electric Lighting Act. They have, perhaps, realised, as have our American cousins, that a well-lighted city is a well-policed city. In the towns of the United States the question of any apparent excess in price has been quite subordinated to the advantages of the increased light, and to the indirect economies they have obtained by it, and few who know anything of the matter can doubt that the extension of the electric light must come about. On this subject I would recall to your mind the words which were spoken at one of our meetings by Mr. Sutherland, the well-known managing director of the Peninsular and Oriental Company. These are the words of that gentleman, whose judgment and sound commercial views bear great weight:—"The other fact to which I would call your attention is the most important of all, and it is this, that the progress of electric lighting is as absolutely certain and sure as anything can possibly be. It may be delayed; it may be hampered; it may be opposed by the great industry of gas, and by quarrels among the proprietors in electric lighting companies; but I think none of us who have eyes to observe can fail to see, day by day and year by year, that the progress of electric lighting is becoming more general and more real." In conclusion, he endorsed the remarks of the Chairman as to the valuable acquisition to the Board in the persons of Lord Sudeley and Major-General Webber.

The CHAIRMAN put the motion, which was carried unanimously.

Mr. H C. GIBBS proposed, and the Hon. Mr. SAUMAREZ seconded, the re-election of the retiring directors, Lord Thurlow, Mr. Sellon, and Colonel Steuart, which was unanimously agreed to. The auditors, Messrs. Cooper Bros. and Co. were afterwards reappointed.

On the motion of Mr. P. COPLAND, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN, in reply, said that he had made a calculation, and he desired to mention it in connection with the subject of relief works. By the amendment of the Act of 1882, he estimated that work could be provided for over three years for more than 10,000 men, at an expenditure of six millions sterling. That would be to do the necessary work in London alone, apart from Liverpool, Manchester, Birmingham, and all the great cities of the country.

The proceedings then terminated.

The Telephone Company of Austria (Limited).

The adjourned second ordinary general meeting of this Company was held at the Company's Offices, 34, Walbrook, on Tuesday last, under the presidency of Mr. Henry Gröwing.

The SECRETARY (Mr. R. Rodgers) read the notice convening the meeting and the minutes of the last meeting, which were confirmed. The report and statement of accounts were taken as read.

The CHAIRMAN, in moving their adoption, said that since the last meeting, which was purely of a formal character, the accounts, which at that time were not ready to be submitted to the shareholders, had to be re-arranged in accordance with the requirements of the law of Austria, which was rather stringent on the point; but after a good deal of correspondence they were approved and passed by the office in London. The results of the Company's operations, as set forth in the balance-sheet, were very satisfactory, considering that they had had to deal with the worst period of the Company's history. The increase both in the number of subscribers and in the revenue continued to advance steadily, and they had every reason to believe that the next report would prove the correctness of their anticipations of future prosperity. The only drawback that they had to contend with at this time of the year was the very severe snowstorms which always occurred in that part of Europe; but he was pleased to say that very little damage had been done to their plant during the present winter months, and their Exchange communications had been almost uninterrupted. This, no doubt, was in a great measure attributable to the solid way in which their telephonic system was constructed, for which he took the present opportunity of complimenting their general manager in Vienna, for whose efficiency and industry the most hearty acknowledgments of the shareholders were due. In consequence of the requirements of the Austrian law which, as he had said, was somewhat exacting, they had been obliged to alter the date of their financial year, which, up to this time, ended with the ordinary year, but which, in future, would date from the 31st March of one year to the same date of the following year. He might say, in conclusion, that the Company's relations with the authorities in Austria, both Governmental and Municipal, were of the most satisfactory character, which was a good augury for the future prosperity of the Company.

Mr. C. L. W. FITZGERALD seconded the motion, which was carried unanimously.

Subsequently, Mr. Gröwing, who retired by rotation from the Directorate, was re-elected, as were also the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., and a vote of thanks having been accorded to the Chairman, the proceedings terminated.

Submarine Telegraph Company.

Report of the Directors to be presented to the meeting of the proprietors, to be held at the Offices of the Company, 2, Throgmorton-avenue, London-wall, E.C., on Tuesday, 16th inst., at one o'clock:—

The receipts for the six months ending 31st December, 1885, amounted to £64,782. 0s. 4½d., being £456. 19s. 11d. more than in the corresponding six months of the year 1884, while the expenses have been less by the sum of £75. 2s. 4d. The net result of the business for the six months enables the Directors to add £8,083. 0s. 10d., the usual proportion of the gross receipts, to the reserve fund, and to recommend a dividend at the rate of 14½ per cent. per annum, leaving a balance of £414. 3s. to be carried to the next account. For the corresponding period of 1884 the dividend was 14 per per cent., and the balance carried over £377. 18s. The receipts from the ordinary traffic for the six months were somewhat less than in 1884, although there were 62,351 more messages transmitted, but the average length of those messages was only 11·44 words, against 11·91 in 1884. There has been also a falling off in the receipts in respect to the messages transmitted, by the Eastern Company over the wire leased to that company, partly by reason of the reduction in the inland rate of telegrams on the 1st October last. But, on the other hand, there has been an increase in the special receipts from the fresh arrangement made with the Indo-European Company, referred to in the last report, and from an agreement recently entered into with the Commercial Cable Company for the use of a special wire to Havre for the transmission of their French-American messages. The Company's cables, as well as those under the care of the Company, have, with two exceptions, been worked during the half-year without any interruption. The exceptions are the Dieppe cable and the cable between Salcombe and Brest; the former was broken on the 14th and repaired on the 22nd December, and the latter was broken on the 25th October and repaired on the 14th December, 1885. In the last report it was stated that the cables during the first six months of the year were also remarkably free from interruption; consequently, the repairing ship was in port for many months. The drawback paid by the insurance company at the expiration of the yearly policy in August was £486, or £160. 10s. more than the charge for insurance for the six months ending December, 1885. This is the reason for the absence of the usual charge in the accounts under the head of "Insurance of Steamer." The sum of £160. 10s. will, moreover, be credited to revenue in the next accounts. An International Telegraph Conference was held at Berlin in August, when the Company was most efficiently represented by Mr. George de Bunsen. The result of the Conference was that some of the telegraph charges were reduced, but the slight modification in the rates between this country and the Continent of Europe will not, it is expected, prejudicially affect the Company's revenue. The new rates do not, however, come into operation until 1st July, 1886. All the Company's cables, as well as those worked by the Company, are at the present time in good working order.

The India Rubber, Gutta Percha, and Telegraph Works Company.

Report of the Directors for the year ending December 31st last, to be presented at the twenty-second ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, on Thursday, the 18th instant, at 12 o'clock noon.

From the accounts it will be seen that the net profit for the past year amounts to £65,662. Adding £40,070. 13s. 3d. brought forward and £52,393. 15s. premium on new shares issued, and deducting £20,779 interim dividend paid in July, there remains a disposable balance of £137,547. 8s. 3d. The Directors have added to the reserve fund £55,000 (which includes the premium on the issue of new shares), and recommend the distribution of a dividend of £1 per share, free of income-tax, amounting to £41,600, making, with the interim dividend, a total payment for the year of 15 per cent., and leaving £40,947. 8s. 3d. to be carried forward. In general sales and in cable work the amount of business done has been up to the average of the last few years. Cables have been manufactured and laid connecting the Cape Verde Islands with the West Coast of Africa, and have been sold to the Eastern and Brazilian Submarine Telegraph companies. Coast cables connecting the Portuguese and French possessions in Western Africa are in course of manufacture, to be laid under a guarantee of traffic from Portugal and an annual subsidy from France. About 600 miles are already laid, and the whole line is to be completed during the present year, and worked by the West African Telegraph Company (Limited). Besides other cable work, 530 miles were manufactured for the Government Indo-European Telegraph Department, and carried out to the Persian Gulf in, and laid from the Company's vessels. The Company's share of the work has been handsomely acknowledged by Sir J. U. Bateman-Champain, K.C.M.G., director-in-chief, in his report to the India Office, recently published. The death of Mr. George Henderson, which occured towards the close of the year, is keenly felt by his colleagues. For more than twenty years he had, as Director and Chairman, given unwearied attention to the Company's interests, often, in times less prosperous than the present, making himself personally liable on its behalf. His health had been failing for some time before his death, but almost to the last the Board had the benefit of his sober judgment and great experience. The Board have appointed Mr. Gray a Director in Mr. Henderson's place, and it is intended that he shall become Managing Director. With a view to this, and to further strengthening of the Board, special resolutions will be submitted to an extraordinary general meeting of shareholders, to be held immediately after the ordinary general meeting. The last of these special resolutions refers to the Company's French works. The Directors bear in mind the possibility that such a sale may be advantageously made sooner or later, and desire to have power to act if the opportunity should occur. Mr. Silver and Mr. Bannatyne, the Directors retiring by rotation, offer themselves for re-election.

The Phosphor-Bronze Company (Limited).

Report of the Directors, to be submitted at the twelfth annual general meeting, to be held at the offices of the Company, on Friday, the 19th inst., at 12 o'clock :—

As will be seen from the accounts the net profits amount to £3,216. 17s., after writing off the whole of the investment in Osborne and Co. (Limited), amounting to £500, £482. 12s. 7d. for depreciation of property, and £391. 18s. 11d. for bad and doubtful debts. Out of this sum your Directors recommend a dividend of 4 per cent. per annum, free of income-tax, which will absorb £2,882. 9s. 7d., and leave £334. 7s. 5d. to be carried to the reserve fund, in liquidation of the debenture liability. The dividend of 4 per cent. will be paid on 27th February next, should the Directors' recommendation be adopted. There has been a slight falling off in the sales of the past year as compared with those of 1884, which, considering the state of trade and the continually increasing competition, is not to be wondered at. The investment of £2,000 in the Sociète Lazare, Weiller and Co. will produce a dividend of 5 per cent. per annum, and profit and loss account has therefore been credited with £100. This, society intends placing a considerable sum to reserve, so that this investment will increase in value. The fact of Messrs. Lazare, Weiller and Co. having done a large trade in wire is also encouraging, as it proves the value of the new silicium-bronze telegraph and telephone wire, for which this Company holds the patents for the United Kingdom, India, the British Colonies and dependencies. The sales of wire, rods, tubes, sheet, and other articles produced by the mills in Birmingham have been larger in the past year than in 1884 ; but, unfortunately, owing to the great depression in trade, many of the Company's Birmingham tenants have left without paying overdue rents, so that now, instead of obtaining £400 per annum for steam power, as formerly, only about £200 per annum are being paid. Over £163 for rents due in 1884, which were regarded as an asset in the last balance-sheet, have been deducted from this year's accounts owing to the utter inability of the tenants, through want of work, to pay anything. It must not be overlooked that the mills, by producing wire, rods, tubes, sheet, and other finished goods, enable the Company to extend the area of its operations, and it requires but a very small extension in the trade of these articles to make the mills highly remunerative ; but in order to meet the requirements of the day constant additions to the plant are necessary. The mills and the old machinery therein, being kept in a good state of repair and preservation, and the expenses connected therewith being debited to revenue, your Directors do not think it necessary to write off this year any sum for depreciation thereon. In the cost of production of the Company's goods at the foundry considerable economy has been effected ; but as the advertising account has always been a very heavy and constantly increasing item of expenditure, your Directors have determined to make a large reduction whilst trade is so depressed. This reduction will be apparent in the next year's accounts. The torpedo boat is now completed, but the unfavourable weather has hitherto precluded any trial ; meanwhile, negotiations are pending for her sale. The legal proceedings in connection with the building of this boat have ended satisfactorily, and at a comparatively trifling cost to the Company. The French Government have, it appears, lately ordered two bronze torpedo boats, which circumstance appears to point to the ultimate adoption of bronze for the hulls of these vessels. In order to secure a return to the Company of some of the Liverpool business, and to execute local orders more promptly, your Directors have, at a small cost, established a branch foundry there, which they anticipate will prove a profitable venture when the trade in that great shipping port begins to revive. This foundry practically pays its expenses already, and will be the means of securing local orders for castings, which would otherwise not be sent to the Company's London foundry. The Company now make and sell gunmetal, brass, and other alloys of a similar character, in the manufacture of which no extra expense is incurred, and as its travellers are enabled to take orders from consumers of metals who will not, or cannot, use the more expensive alloys of phosphor-bronze, it is hoped that the Company will soon have a much larger volume of trade. Since the ciricular issued on the 17th July, 1885, Vice-Admiral Sir J. Edmund Commerell, V.C., K.C.B., M.P., has joined the Board, and Mr. J. W. Bushby has just resigned the chairmanship in his favour, but remains a Director. One director (Sir J. E. Commerell) retires at this meeting, under the Articles of Association, and, being eligible, offers himself for re-election. Mr. James Rock has given due notice of his wish to become a Director again, having, your Directors are happy to say, been completely restored to health. The accounts have been audited by Mr. R. Payne, F.C.A. (Messrs. Payne and Henry, chartered accountants,), and Mr. R. Peters, the duly appointed auditors of the Company, who offer themselves for re-election.

BUSINESS NOTICE.—Messrs. Woodhouse and Rawson have been appointed by Mr. A. P. Trotter special agents in Great Britain and the Colonies, and sole agents on the Continent, for the sale of his patent dioptric glass.

NOTES.

Texas.—San Angelo, Texas, is considering a proposition for the establishment of an electric plant.

At the Cafe de Paris, Paris.—The electric light is now being installed in this café. The dynamo is driven by a compressed air motor.

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 12th inst. amounted to £3,399.

The Telephone in the United States.—It is said that there are three times as many telephones in the United States as in the whole of Europe.

Lecture.—To-morrow, at Sarbonne, M. Pillat, lecturer to the Faculté des Sciences, will discourse upon "Electrical Machines, Ancient and Modern."

Obituary.—The death has been announced of M. Jules Jamin, permanent secretary of the Académie des Sciences, and Professor of the Ecole Polytechnique.

The West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ended 15th inst. are £2,551, as compared with £2,339 in the corresponding period of 1885.

Underground Wires in Paris.—There are now about 461 miles of telegraph and telephone wires laid in the sewers of Paris. The Government is making new regulations with a view to decreasing the tax upon lines so laid.

Where is It?—In reply to our note under the above heading in last week's issue we have been inundated with assurances that Blackpool and not Blackwall is the place in question. We thank our correspondents for the information.

The New Postmaster General.—As the present Postmaster-General sits in the House of Lords, business relating to the Post Office in the House of Commons will be attended to by Mr. H. H. Fowler, the Financial Secretary to the Treasury.

Bulgaria and Eastern Roumelia. — The public are informed that telegrams for Servia, Bulgaria, and Eastern Roumelia are now accepted under the ordinary conditions, and not at sender's risk, which has been the rule since last November.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended 12th inst. were £2,646, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

A New Current Indicator.—A "new" current indicator is described in the present issue of the *Electrical World* as being the invention of Mr. Streeter, of Chicago. We fail, however, to see in what way it differs from the ammeter of M. Lalande described in these columns some months ago.

The New Post Office in Belfast.—Workmen are now being employed in laying the underground wires in Rosemary-street to the new Post Office in Royal-avenue. They were also engaged in attaching them to the wooden structure on the roof of the building. Business, it is expected, will be commenced next month.

Town Lighting.—It is proposed to electrically light St. Tropez, a small and picturesque seaport town, in the department of the Var and the arrondissement of Draguignan, on the shore of the Bay of Grimaud, thirty-eight miles E.N.E. of Toulon. The municipality, it is said, is asking for proposals from different electric lighting companies.

A Telephone Service between Paris and Brussels.—It is announced that telephonic communication is to be established between Paris and Lille, on the Van Rysselburghe system. The projected line between Paris and Brussels may therefore be put into practical effect before long. The two Governments, it is said, are at present considering the matter.

The Telephone in Portugal.—According to recent advices from Portugal the telephone exchanges at Lisbon and Oporto had at the end of October last 329 and 232 subscribers respectively. The Edison-Gower Bell Telephone Company, of Europe, had installed 168 lines in Lisbon and 97 in Oporto; there being a total of 826 telephones in service in the country.

Academie des Sciences.—At the last meeting of this Society M. Lippman was elected, by 31 votes as against 20 for M. Henri Becquerel, to the vacancy in the physical section formerly filled by M. Desains. Among the papers recently read before this Society was one by M. Trouvé, in which he detailed the results obtained by the method of Electro-Polyscopy, of which he is the inventor.

A Hot Dispute!—A French contemporary, commenting upon the claims of M. Marcel Deprez to the invention of the transmission of force by electricity, suggests that while this is questionable M. Deprez has an undoubted right to priority of invention in the matter of the transmission of *heat* by electricity. His method of burning up a distant motor is at once effective and unique.

Electricity and Mines.—The mines of Meurchin, Pas-de-Calais, have received an installation of arc and incandescent lamps, variously arranged. This has been put down by Messrs. Sautter, Lemonnier, and Co., and comprises 11 arc lamps of about 1,000 candle-power, and the same number of incandescents The mines of Blanzy, Saône-et-Loire, have also received a similar installation.

The Patent Laws.—The President of the Board of Trade (Mr. Mundella) has reappointed the committee instituted by his predecessor, to inquire into the working of the Patent Laws, and has requested Baron H. DeWorms, M.P., to continue to act as chairman. Sir R. Webster, Q.C., M.P., will take the place of the Lord Chancellor, and Mr. Acland, the present Parliamentary Secretary to the Board of Trade, and Sir Bernard Samuelson, Bart., will be added to the Committee.

Electricity for Cutting Coal.—An American paper mentions the fact that "Electricity has been employed to cut coal in some of the mines in Illinois, because it would not hold mass meetings and strike for higher wages." The cutting is described as done by a chisel at the end of a steel bar, fastened to a piston of soft iron in the middle of a cylindrical coil of insulated wire, and the desired reciprocating motion is given to the rod by reversing the current in the coils.

Society of Telegraph-Engineers and Electricians.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, Westminster, S.W., on Thursday, Feb. 25. There will be a council meeting at 7 p.m., and an ordinary general meeting at 8 p.m., when there will be a further discussion upon "The Self-induction of an Electric Current in Relation to the Nature and Form of its Conductor," by Prof. D. E. Hughes, F.R.S., president.

Edison and the Telephone.—Interviewed about the pending contest, Edison said:—"The principal part of the telephone is mine. The carbon transmitter was invented by me, and is

Digitized by Google

in use all over the world. I sold it to the Western Union for $6,000 a year royalty for seventeen years, and the Western Union receives about $300,000 a year for it from the telephone company. That's business, and it's all right. But the Bell monopoly has had a fight for its life in England, France, and Canada, and it is held there by virtue of my carbon transmitter."

ELECTRICAL TRAINING GEAR.—*The Engineer* says :—"The question of training and working heavy guns by means of electrical motors has for some time occupied the attention of the War Office authorities, who have carried out a series of experiments. The system of employing small motors, actuated by a dynamo machine driven by a steam engine placed under cover in a sheltered position, will probably be adopted in preference to the present plan of transmitting the motive power by means of shafting. The guns of the Spithead forts are to be immediately fitted with the new electrical training gear."

TELEGRAPHIC COMMUNICATION AT OXENHOPE.—At a recent meeting of the Oxenhope Local Board with reference to the memorial recently submitted by the Board to the Postmaster-General, asking for the establishment of a telegraph office in the district, the clerk read a communication stating that the application had received careful consideration, but as it was estimated that the revenue from telegraph business would not pay the working expenses an office could not be established except under a guarantee of £38 per annum, under an agreement for seven years. The Board were not in a position to take any steps in the matter.

THE CENTRAL LABORATORY FOR FRANCE.—It will be remembered that some time ago the Société Internationale des Electriciens—which, by the way, is a more energetic body than its English prototype, in that its committees sometimes bring matters to an issue—appointed a committee to report upon the question of the establishment of a central electrical laboratory in France. The report of this committee has been presented by M. E. Sartiaux, and approved by the Council. Whether anything further will come of it remains to be seen. We hear that the motive power provided is ridiculously inadequate for the requirements of an institution of the kind proposed.

POST OFFICE TELEGRAPHS.—A return has been issued, in accordance with an order voted in the House of Commons, showing the gross amount received and the gross amount expended in respect of the telegraph service from the date of the transfer of the telegraphs to the State in 1870 to the 31st day of March, 1885. From this it appears that the total receipts in 1885 amounted to £1,784,414, which sum was less by £36,350 than the expenditure for the same year—£1,820,764. In the year 1884 the expenditure was £1,789,223, and the deficit then was £19,697. These are the only two years since 1870 in which the expenditure has been higher than the receipts.

COMMUNICATIONS WITH TRAINS IN MOTION. — We are informed that Messrs. Edison and Gilliland have concluded a modification of the original idea of Mr. W. Wiley Smith, of communicating with trains in motion by means of static induction between the metal roof of the carriages and a wire running parallel with the line, and are about to make the results public. The apparatus, both on the train and at the station, is said to consist of the ordinary Morse key, a telephone as a receiver, and an induction coil for charging the wire and roofs of the cars respectively. A vibrating reed in the circuit gives a continuous musical note in the telephone, which is broken into dots and dashes by the closing of the Morse key.

THE GROWTH OF THE TELEPHONE.—The growth of the telephone, says the Boston (U.S.) *Transcript*, is one of the most remarkable in the history of inventions. In August, 1877, the number of instruments in use in this country was only 780, while in February, 1880, there were 60,800, 249,700 in 1883, 307,010 in 1884, and in February, 1885, 325,574. There are about 18,000 in Canada, and 13,000 in Great Britain. The number of exchanges has grown from 100 in 1880 to 782 in 1885. In January last there were 137,223 miles of telephone wire in this country. There are 5,186 persons furnished with employment by the exchanges. More different patents have been issued on the telephone than in any other single line of invention in this country. The total number for the ten years is 1,521.

THE INTERNATIONAL EXHIBITION, EDINBURGH. — The machinery department of the International Exhibition will be one of the most important of the kind that has been seen. There will be twelve engines giving power for the electric light and for the machinery in motion, developing in all about 1,400 horse-power. There will be four lines of shafting running through the machinery department, giving power to about 120 exhibitors of looms, spinning machinery, printing, and to paper making, soda water, chocolate, cocoa, and other food manufacturers, as well as about twelve firms of bakers and confectioners. There will also be about 900ft. of steam pipes for conveying steam to prime movers, as well as to the exhibitors requiring steam for their own exhibits. Six boilers are to be provided of 1,200 horse-power.

UNIVERSAL TIME.—At a meeting of the Prime Meridian Metric and Decimal Committee of the Balloon Society, held recently, Mr. Le Fevre, C.E., the president of the society, stated that although the committee had not succeeded to any great extent in the adoption of the 24 o'clock system in this country, it was due to the opposition of the president of the Horological Institute and the "Nautical Almanack." In Australia the telegraphs owned by the Government had carried it out. Spain, Italy, and Germany had partially adopted it. A resolution was moved by Mr. T. H. Hall, C.E., that a deputation should wait upon Lord Wolverton, the Postmaster-General, urging the necessity of transmitting all telegrams from America, the Colonies, and abroad, where the 24 o'clock time is in use, to the postal telegraph offices in the United Kingdom by this new system. The resolution was carried.

THE TELEPHONE IN TORQUAY.—A local contemporary says :—"A petition was on Monday filed against the Torquay Harbour Purchase Bill by the Western Counties and South Wales Telephone Company. There are clauses in the Bill which the companies think will greatly impede if not altogether put an end to their business arrangements, and therefore in self-defence they are obliged to appear in opposition. It seems very undesirable that the Torquay ratepayers should run the risk of having to fight the question of 'overhead' wires, which is really a national one, and ought to be fought out over a special Bill brought in by some responsible authority, such as the Board of Trade, or by some of the wealthier Corporations. It is, perhaps, right that local authorities should have some control over these wires, but the Torquay Local Board ask for very much more—hence the opposition. The Board, it is understood, was offered reasonable terms by the Company, but without result."

ELECTRIC LIGHTING IN HOLLAND.—A contemporary says: —One trifling matter about a little manufacturing town may

Digitized by Google

illustrate the difference between the modes of social organisation prevalent in this country and in Holland. There are between two thousand and three thousand residents in the little place, and when the leading inhabitants wished to have it illuminated by the electric light, this is how they set to work. A syndicate was formed, composed of every householder in the town, each one of whom undertook to guarantee a proportion of the nominal capital sum of the combination, assessed to him upon the basis of the ratable value of his dwelling. Thus a small levy all round sufficed to pay for the plant of the concern, and the cost of maintenance and annual working expenses was divided *pro rata*, according to the number of lights used, amongst the householders, no profit of any kind being made by the managers of the works. Under what difficulties, and at what cost, similar little places in England are lighted we all know.

THE ELECTRIC LIGHTING ACT.—Commenting on the desirability of neglecting no means of finding employment for industrious men who have no work to do, the *St. James's Gazette* mentions for one thing that "all attempts to establish a system of electric lighting in the thoroughfares and elsewhere are crushed by the provisions of the Electric Lighting Act of 1882. The restrictions of that Act are so excessive that it is impossible to work under them. To these restrictions Lord Salisbury called attention the other day in connection with the industrial 'depression' which causes so much misery and anxiety just now. The long and the short of it is that nobody dares to venture on electric lighting works on any considerable scale because of Mr. Chamberlain's Act, which virtually extends the Protective system to the gas companies. Reasonable conditions should be imposed on the electric light companies, of course; but they should have a fair chance, and if they had, a great new industry would be developed at once."

THE ALARMIST IN BELGIUM.—After M. Somzee, the gas champion of Brussels and one of the gentlemen who have arrogated to themselves the honour of the invention of the incandescent lamp, had poured four columns of remonstrance against the progress of electric lighting, on the ground of its danger to human life, into the ears of the members of the Chambre des Representants, he was quietly sat upon by the Minister who, while acknowledging the statement of M. Somzee that a number of accidents had in foreign countries resulted upon the use of currents of high tension, remarked that he was not aware that any such accidents had occurred in Belgium. On the other hand, gas was a constant and fruitful source of danger to life, and frequent explosions, which were attended with grave results, had been due to the use of petroleum. He considered it fatal to progress to unduly hamper any industry; but did M. Somzee insist upon it he would be happy to lay his observations before his colleagues, who would, if they thought proper, appoint a commission to inquire into and report upon the best means to be adopted to guard against accidents.

THE NOUVEAU CIRQUE INSTALLATION.—The installation at the Nouveau Cirque at Paris has been formally inaugurated. As now modified, it comprises ten Jablochkoff lamps, eight sun lamps suspended in lustres, and a circle of 400 10 candle-power Edison incandescents. In the boxes and on the corridors and staircases a number of incandescents are variously placed; while five Street and Maquaire lamps light up the entrance. Four sun lamps are always arranged in the *café*. The total number of incandescents in the building is about 1,200. The arc lamps and Jablochkoff candles are supplied in current by two Maquaire alternative current machines, excited by two small Gramme dynamos. The incandescents are supplied by two Edison machines and a battery of 60 Jarriant accumulators. These latter are charged during the day by one of the Edison dynamos. The incandescent lamps are arranged in three circuits, in such a manner as to prevent a complete breakdown. For instance, of each group of five lamps in the boxes two are served by one of the dynamos, two by another, and one by the secondary battery; the circle of 400 lamps is divided into 20 groups, served alternately by each dynamo, and so on. Steam power is employed to drive the dynamos, in the form of a twin-cylinder engine of 120 horse-power, by Lecouteur and Garnier; a spare engine of 25 horse-power has also been provided.

THE ARCHITECTURAL EXHIBITION AT SHEFFIELD.—Among the exhibits at this Exhibition is that of Messrs. Tasker, Sons, and Co., of Sheffield, who make an attractive display under the head of Domestic Electricity. There are electric bells of an improved description for calling the servants; electric bells for attaching to windows and doors which will ring in case either should be left open accidentally at night, or attempted to be opened by burglars; electric bells connected to mercurial thermostats to ring in case of fire, or any undue rise of temperature in the house or greenhouse. Electric telephones are connected to the Central Exchange to accommodate visitors to the Exhibition, and also to demonstrate the convenience of telephone connection in the house; mechanical telephones, which are especially suited for use between house and stable, or house and lodge; electric light machinery for lighting the house by means of incandescent lamps. In wire-sewn leather belting a sample belt is shown measuring 60ft. long by 16in. wide. Here is also a leather belt made for a large firm in the town 80ft. long by 8in. wide, and of three thicknesses. A rubber and cotton driving band, also made for a local firm, is 64ft. long, by 18in. wide, by half an inch thick. Solid woven hair belting has lately come into favour, and the largest belt of this description yet made is shown, being 101ft. long by 21in. wide. A further belt of this class, now being manufactured for local use, is 25in. wide.

WATERMARKING AS A PREVENTION OF FRAUD.—In an article upon this subject in the *Paper Trade Review* Mr. Richard Herring says: Postal orders watermarked for one shilling have been purchased and the watermark altered to ten shillings and twenty shillings. To effect this alteration the paper had been first softened but not resized, and the Post Office consequently suggests that a few light marks should be made with a pen on the back of the watermark, when the ink, we are told, will spread if the paper has been tampered with. Trifles are as expressive as larger things, and if a papermark by machine is to be adopted in imitation and substitution of the original watermark produced naturally on a handmould, there will be no greater difficulty in changing a five pound Bank note into five hundred than has been surmounted in changing a shilling postal note into twenty shillings. However, the substitution of a papermaking *machine* for a paper *mould* will admit of many novel ways of preventing the fraudulent imitation of watermarks so called. The water which dilutes the pulp and the water which dissolves the size are each equally available at different stages of the manufacture to introduce new and separate features and combinations which an electric current will convert into impossible transformation. Indeed, those parts of a money note which have chief importance could be indicated entirely by electricity without printing in the process of making the paper; but why should not the printing with special ink be accomplished before the paper is

Digitized by Google
UNIVERSITY OF CALIFORNIA

sized and finished, the surfacing metal being ultimately employed to impart a visible and unalterable finish to the notes by electricity ?

ELECTRICAL DEFINITIONS.—On Tuesday last, M. Emile Bède opened a conference on this subject before the Belgian Society of Electricians, Brussels. After premising that the fundamental notion of electrical, like that of physical and mechanical science, is that of work, which is the product of force by length, and the source of which is always energy, either stored up or renewed, the speaker said that in all electrical manifestations the production of mechanical work, whether direct or in the form of heat, could be distinctly traced. Luminous phenomena were often produced at the same time; and, if the unit of light could be defined as exactly as that of heat, it would be easy to establish the mechanical equivalent of light. In electrical, as in other branches of science, great difficulty was experienced in suitably determining the two factors of energy and work called "quantity of electricity," difference of potential," or "electromotive force;" and it might be asked if there would not be an advantage in defining these quantities otherwise than as at present. For instance, if, instead of adopting the units of the C.-G.-S. system, the metre and kilogram were taken as units of length and weight, the product of the quantity by the difference of potential would give the product of the two practical units, viz., the coulomb and the volt; but, for each of the two factors of the product neither the volt nor the coulomb is found. M. Bède also criticised the too great number of terms employed in electrical science, and thought that at any rate electricians might abstain from employing a word to express the flow or delivery of a coulomb per second. Hydraulic engineers had never thought of terming a prony the flow of a cubic metre of water per second, and why should there be a word to express a coulomb contained in a condenser under the tension of a volt ?

SCIENCE FOR THE PEOPLE.—*Apropos* of Prof. Bell's recent suggestion for utilising an overboard telephone wire at sea, the *Daily Telegraph*, a few days ago, edified its readers in the following strain:—"Prof. Bell, who gave us the telephone, promises us an almost greater marvel, as a result of certain experiments which he has been recently making as to the conductivity of water. He has discovered that if a ship trails a long wire behind it in the sea, and that wire is attached to a dynamo on board the vessel, an extraordinary amount of electrical action is at once set up in the waves. Let us suppose this long wire trailing behind an Atlantic liner. The wire may be five miles in length, and it has a dynamo attached to it at its ship end, in full working order. Then the remarkable and unimagined fact which the inventive Professor has revealed to the world is that a powerful electrical current is set up in a circle all round the ship, and that this current is strong enough to influence a telephone which may happen to come within that circle. As the length of the wire is five miles, the diameter of the circle would be ten miles; and thus a ship could surround itself at will with a protective electric circle, which would inform those on board whenever anything approached within five miles. The circular current constantly at work would form a guard to an ironclad far better than any torpedo net ever yet invented; a ship would be able to feel its way in the water by means of the dangling wire just as a cat does in the dark by its whiskers. Now, there is nothing at all new in the fact that water is a good conductor of electricity. This has been known ever since Franklin's experiment with the kite, if not before. Yet it is quite novel and unheard-of that the electricity sent along a wire which is dropped into the waves, instead of passing off uselessly into the sea, should begin to circulate all round the centre at an equal distance, and that the current so established should be powerful enough to set a telephone at work."

THE ELECTRIC LIGHT AND SURGERY.—Mr. Davidson, in the current issue of the *Lancet*, describes an application of the electric light to the opthalmoscope. He says:—The incandescent form of electric light is so convenient in many ways, that it is not surprising to find it has been adapted to sundry medical instruments. To adapt it to the opthalmoscope I finally decided upon the following plan—viz., to fix a small incandescent Swan lamp close to the oblique mirror of an opthalmoscope, arranged in such a way that the light from the lamp should be reflected to a focus in a direct line with the sight hole, so that the brightest illumination should always be exactly in front of the sight hole. As the lamp is fixed to the opthalmoscope and moved with it, it follows that the relation of the illuminated spot and the sight hole never varies. The instrument is intended for the direct method of examination of the eye, and is used precisely in the same way as the ordinary opthalmoscope. The light is pleasant, and quite as well borne as the usual gas or lamp light used in opthalmoscopic examinations. By this arrangement it is easy for an inexperienced person to see the fundus oculi, and especially so if the pupil be dilated. The light is on the spot he looks at, and always follows the movements of the instrument. The light is never lost. On this account it may prove a useful demonstrating opthalmoscope. The colour of the parts is nearer that seen by daylight than can be got by the ordinary artificial light. The lamp can be detached in a second, and used independently for oblique illumination in examining the cornea or lens. I have used this lamp in needling operations. The opthalmoscope can be used in the ordinary way, since the oblique mirror can be removed, the additions in no way interfering with it. As to the source of the current, I have used lately four cells modified Leclanché battery. This gives a moderate light for about eight minutes, and then requires 20 minutes' rest. The bichromate battery, as employed at Moorfields Eye Hospital, is probably the best form of stationary battery. Two small Grove cells will give a good light with this lamp for three or four hours or more. Pocket accumulators have hitherto disappointed me. Mr. Joseph Swan has recently made a reliable accumulator, which is quite portable, and, fixed with a specially constructed Swan lamp, gives a good light for 12 hours. It can then be recharged.

THE ELECTRIC LIGHT IN CHICAGO.—Among the large installations which have recently been completed in Chicago may be mentioned those at the City Hall, the Washington-street tunnel, and the Lasalle-street tunnel. The plant at the City Hall, as furnished by the Edison Company, cost something over $40,000, the engines being built expressly for this purpose. The engines are odd in size, the cylinder of the larger measuring 21 by 15in.; that of the smaller 18½ by 15in., and when running at full speed they each make 240 revolutions per minute. When running at this high rate of speed the four dynamos will generate electricity for 1,600 incandescent lights of 16 candle power. The limit number of lamps that will be required at any one time is 1,400. Three hundred of these have been reserved for the tunnels, connections being made with the City Hall wires by means of cables laid in pipes, as furnished by the Underground Conduit Company. In the Lasalle-street tunnel 134 lamps will be kept constantly burning, with 26 extra lamps for night use only. The Washington-street tunnel will have the same number of night lamps and 100 for constant use. It has

Digitized by Google

required the laying of 12,800ft. of cable to transmit the current for the tunnels, and in this connection may be mentioned the fact that this is the only plant in use in this city where two sets of lights with distance intervening are kept burning at the same time, the candle-power being equal in both, and that regardless of the number of lamps burning in each set. Another very important feature is that the plant is so constructed that the two distinct sets of lamps (the City Hall and the tunnels) can be operated upon a common circuit by one or any number of machines, or the two sets can be operated upon totally distinct circuits and by separate machinery, so that the shifting from one method of operation to another can be made with perfect ease, and without affecting the candle-power of the lamps a particle. The Washington-street tunnel is about 1,280ft. in length, and the distance of the dynamo from the centre is 1,950ft. There are in this tunnel 128 16 candle-power incandescent lamps. The length of the Lasalle-street tunnel is 1,800ft., the distance of the dynamo from the centre 1,450ft, and the number of 16 candle-power lamps is 166. For this service feeders are laid underground in a special Dorsett conduit. At the City Hall the electrical and mechanical plant is located in the basement. There are two Armington and Sims engines, two No. 12 Edison dynamos, and a No. 16 dynamo of the same type.

Aluminum.—In a recent paper to the Franklin Institute, given in full in the *Journal* of the Institute, Mr. Cowles describes the method of obtaining aluminum and its alloys by the use of his electric furnace. After describing his furnace (*vide The Electrician*, Vol. XV. p. 411), he goes on to say, "All is now ready for the charge, which is prepared. Should it be desired to produce aluminum bronze, we mix sixteen or eighteen pounds of granulated copper, twelve to fourteen pounds of aluminum oxide in the form of broken corundum, and several pounds of coarsely broken charcoal together, burying the electrodes with the same, and thus filling the space inside the walls of the sheet-iron gauge. The gauge is then lifted from the furnace, additional coarse charcoal is spread over the entire mass, the iron top of box is put in place, the seams luted with fire clay, the current from the dynamo switched on, and the furnace is in operation in but little more time than it has taken to give these apparently trifling but very important details. We will now proceed to make a little study of the philosophy of the process, after first watching a successful 'run' or 'heat' from the beginning to the close of the operation. Of course, the furnace and its contents, when the current of electricity was turned on, were entirely cold and the resistance presented to the flow of the current consequently is higher than it would be at any time during the 'heat,' unless some unforeseen accident, such as a slight explosion of gas, takes place. But notwithstanding that the furnace is cold, a complete metallic circuit, with carbon tips dangerously near together, is ready to convey a one hundred horse-power flash of lightning into the furnace, should a short circuit occur. There are likewise many pounds of pure copper in between and about these carbon tips that may be melted and run together and thus produce a short circuit. With these conditions an electrician would insist that the man in charge of the furnace should look pretty sharply lest the four-thousand dollar dynamo at the other end of the wire be burned out, or somebody be injured by a heavy flash. The man in charge, however, has anticipated such a contingency by having thrown in several coils of the resistance box, so that under no condition, even if the great carbons in the furnace were pressed tight together, would the dynamo be able to produce a current of more than 1,600 amperes, the maximum load. Upon watching the amperemeter, however, it is seen that this precaution was not necessary, for only about 200 amperes are indicated as flowing; the artificial resistance is, therefore, slightly diminished; the needle of the ammeter moves up rapidly to 600 or 800 amperes. Suddenly it gives a jump up to 1,200, then back to 200, then with a bang the armature of the ammeter is brought against the magnet, and it registers 1,600 amperes of current flowing and then instantly drops back to almost zero. As every jump of that needle means wear and tear on the commutator and brushes of the dynamo, care is now taken to keep more control of the current, and a little more artificial resistance is thrown into the circuit. The needle now moves more slowly around the dial, gradually making fewer and fewer jumps, and at the end of eight or ten minutes, it has worked up to the 1,000 ampere mark, and becomes quite steady. Suddenly there is a hiss and a sharp report, a tongue of greenish yellow copper flame darts upwards from the hole in the furnace top and then disappears, to be followed after a minute or so by a slight vapour. This was caused by the monoxide of carbon combining with the atmosphere in the furnace to produce an explosive compound. To prevent this gas from accumulating to an extent to raise the furnace top and loosen the luting, the attendant holds a lighted stick over the vent and a series of slight explosions follow. Soon a characteristic yellow-white flame appears above the hole, the needle registers about 1,200 amperes of current flowing, all of the artificial resistance is withdrawn, and the process of reducing aluminum and alloying it directly with copper is completely under way. Soon the needle gradually creeps around the dial to the 1,400 or 1,500 ampere mark. This is regarded as being a little too hot work for the dynamo and at the same time the plume of flame above the furnace indicates a little less rapid reduction. There are, therefore, two things now necessary. The first is to put more resistance into the circuit, and the second is to put more ore into the zone of reduction. These are both done by withdrawing one of the electrodes and the ammeter needle drops back to 1,200, and the flame above the furnace soon gives evidence of doing more work, by reason of more copious white fumes being given off. This pulling out of the electrodes is repeated over and over again until both are out to their full length. At the end of an hour the 'heat' is completed. The current is then switched to another furnace, but one furnace being used at a heat. The artificial resistance is again resorted to, enough being thrown into the circuit gradually, thus slowly choking off the current, permitting the proper regulation of the brushes on the dynamo, and also giving time for the engine to govern itself. Finally, at the end of several minutes, the switch is thrown open and the furnace is entirely out of the circuit. Furnace No. 2 is now operated in precisely the same manner as the furnace No. 1, which is allowed to cool off. At the end of two hours furnace No. 2 is thrown out of the circuit and work begun on furnace No. 3. By this time No. 1 is ready to be discharged. The lid is removed and water is used with a sprinkling pot to quench the fire still remaining. At the bottom of the furnace, on the floor of fine charcoal, is found an oblong metallic and crystalline mass of white metal. It is the copper charged with from 15 to 35 per cent. of aluminum and a small quantity of silicon. It frequently averages 20 per cent. to 22 per cent. of aluminum and silicon. Covering this mass is also found a considerable quantity of fused carbide of aluminum. Analysis of this product has shown 30 to 60 per cent. of metallic aluminum present. On cooling, it forms very large and distinct crystals."

TELPHERAGE.*

BY PROFESSOR JOHN PERRY, F.R.S.

In my preliminary lecture last week I tried to show you

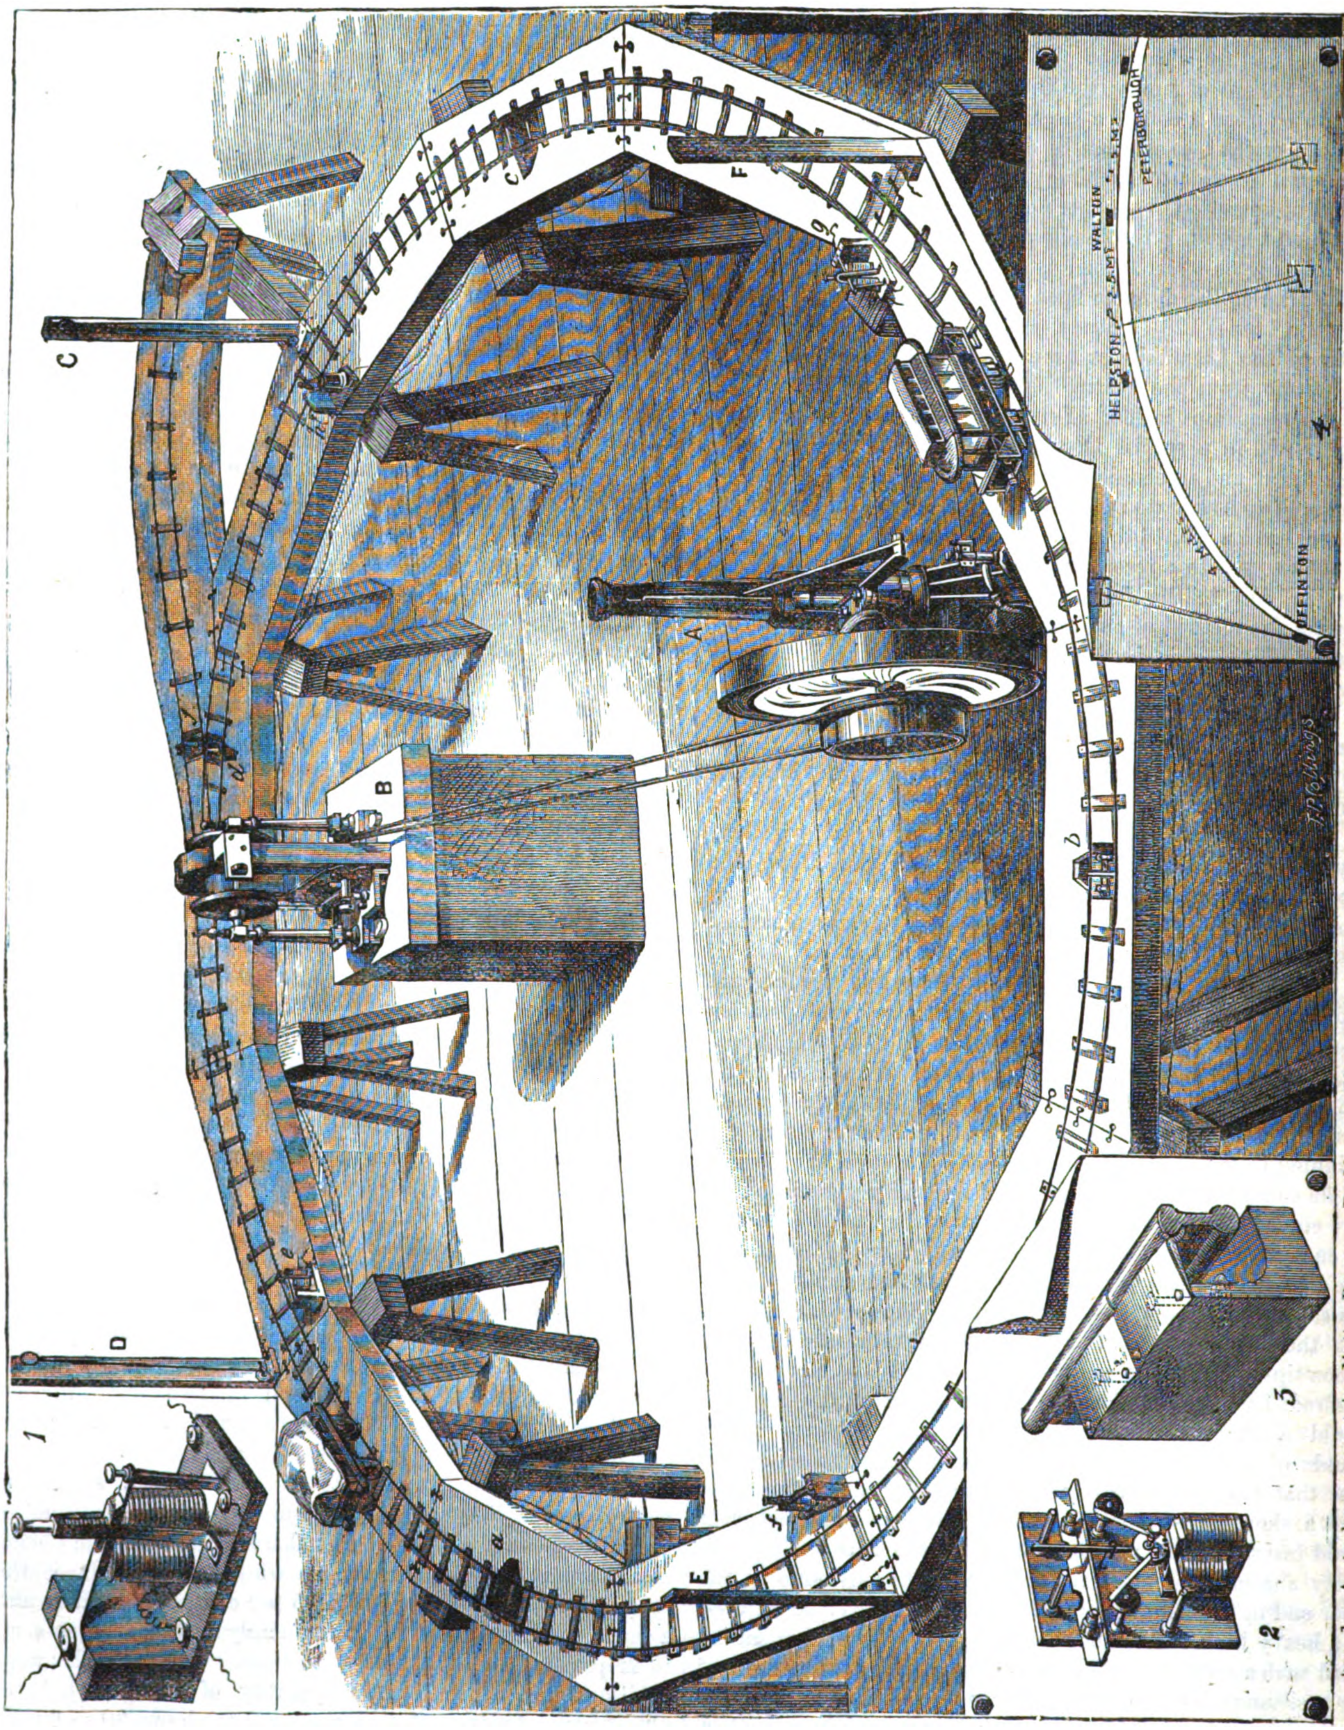

Fig. 1.—A. An Engine supplying Motive Power. B. Magneto-Electric Machine. C, D, E, F. Electric Current Indicators. *a, b, c, d.* Contact Makers at the ends of each section. *e, f, g, h.* Blocking Electro-Magnets attached to each section. 1. Blocking Electro-Magnet (enlarged). 2. Contact Maker as in the Model. 3. Contact Maker required for actual use. 4. Map Indicator for automatically showing the position of the Trains on the Line.

why it was that we spoke of a *current* of something flowing in a circuit from one of our generators, and also our reason for calling it a current of *electricity*. I proved to you that our method for measuring the loss of electrical energy in any portion of the circuit was a correct one, and I showed you what were the difficulties in transmitting electric power to great distances, due to the heating of the conductors. As the power which must be received at a distant place depends upon the available

* Lecture delivered at the London Institution on "Telpherage," 28th January.

Digitized by Google

potential there, and as the available potential there is less as the distance is greater and as the current is greater, and as the current itself must be greater for a certain amount of power the less the available potential, the lessening of this available potential is more rapid than the increase of distance. In describing the wonderful results obtained by M. Marcel Deprez at Creil, I pointed out how different our problem is in England, where on such telpher lines as that at Glynde we are limited to an electric potential or pressure of 200 volts instead of the 6,000 volts employed by M. Deprez. I further showed you how the potential falls off along such a line when carrying 84,000 tons per annum, and that we might have such lines working very economically ten miles long, even with the restrictions imposed upon us by the Board of Trade.

The energy employed in the driving of carriages must either travel with the carriage in a stored condition, as it is stored in a horse or in the coals of a railway locomotive, or in the compressed air of some forms of tramway locomotive, or in the electrical accumulators which Prof. Ayrton and I have carried on our electrical tricycle and in tramcars ; or the energy may be conveyed to the carriage from a distance, as in wire rope tramways and other cases of haulage, and in the pneumatic tube system.

Electrical power seems to be the only kind of power, with the exception of that which is used in haulage, which can readily be transmitted to a rapidly moving carriage, and its applicability in this case seems to have struck inventors very early in the history of the applications of electricity, so that models of electric railways, worked from voltaic cells, have been used for a considerable length of time. As soon as the discovery of the Dynamo Machine gave us the means of producing electrical power readily in large quantities, the Siemens railways in Berlin and at the Paris Exhibition were constructed, and not long afterwards the electric tramway at Portrush, which is six miles long, was made, as well as a very much shorter one on the beach at Brighton, both being now in daily use. In electrical railways it is of the greatest importance that one of the conductors should be well insulated from the other; that is, as I explained in my last lecture, that it should not be possible for leakage to take place from one to the other. In the Siemens' tramway along the Champs Elysées leakage was prevented by carrying both the conductors or insulators above the level of the tramcar on wooden structures, a plan to which there are many serious objections when proposed for a general system of electric railways. On Brighton beach the line is so short and the shingle on which the sleepers of the tramway rest is so well drained that sufficient leakage does not occur to materially affect the working, although the rails themselves are the two conductors. In this case, therefore, where the motor on the tramcar receives a current through metallic contacts with the two rails, it is driven wherever it may be on the line. On the Portrush tramway, however, which, as already mentioned, is six miles long, this method was found to produce too much leakage for practical working, and one of the conductors had to be raised about two feet above the ground. This conductor is a stiff T iron, which is supported on many wooden posts, and is insulated from the posts. Long before either of these two railways was projected, my colleague and I saw that the plan used at Lichterfelde, near Berlin, and now employed at Brighton, was the only one which promised success in a general system of electrical locomotion; but to avoid the excessive leakage that would occur on long railways, it would be necessary to divide the railway up into sections, and arrange matters so that the rail to be rubbed should be automatically connected with a buried well insulated conductor just when a train was in the neighbourhood. By this device leakage would only occur on a short length of the railway at any instant, so that the leakage on a long electrical railway would be actually less than on a very short railway made in the older way. We further saw that this division into sections enabled us to provide an automatic block of a far more perfect kind than any known in ordinary locomotion. It was analogous to the instantaneous removal of all steam, and coal, and heat from an ordinary locomotive when it was approaching dangerously near another train in front of it, and all this would be effected automatically without the agency of a driver, guard, or signalman. Our plans were all simple, and some of them would have enabled us to obtain good insulation of the line even if the rails had been covered to the depth of a foot with water. I will now throw on the screen the slide (Fig. 1) taken from the large wood cut published in the *Graphic* newspaper, showing the model which illustrated our system in a lecture delivered by Prof. Ayrton in 1882, before the Royal Institution.

[Prof. Ayrton had provided two trains, one moving slowly, which represented a goods train, and the other moving much more rapidly, representing an express train, following it. It was interesting to see the attempts made by the express train to catch up and run into the goods train, and the way in which it was constantly being stopped by its supply of electric power being cut off whenever it came within a certain distance of the goods train in front of it.]

By this time it had become evident that the success of our insulation method, important as it was, was of less moment than the automatic block, which enabled carriages to be run without any attention from drivers, and after Prof. Ayrton's lecture we received many suggestions of possible applications of the principle of the automatic transmission of carriages by electricity.

We had already made sketches of two forms of overhead single rails, with wheels running on them from which hung the loads to be carried.

Among the suggestions we received regarding possible uses of our "Absolute Block" was a very valuable one sent us by Prof. Fleeming Jenkin from Edinburgh, describing an overhead railway, which should consist of a single wire rope, which was itself the carrier of weights, and also of electricity. As he himself said in his introductory address to his students at the University of Edinburgh, he had long had the idea that there must be some method of propelling electrically a continuous stream of light trains along an elevated single rail or rope, but that he did not see his way to carry this idea into practice until he read an account of Prof. Ayrton's lecture at the Royal Institution, when it was plain that the plan of sub-dividing the rail electrically into sections and of providing an automatic block would enable him to have a great number of trains following each other without drivers, and without there being any danger of collision. The position held by Prof. Jenkin in the engineering and scientific world was such that we shall always consider it a great honour to have been asked by him to become his partners in any scheme of this kind, and we gladly accepted his offer to co-operate with him in developing a system of automatic electric transport, to which he gave the name of "*Telpherage.*"

The first model of a Telpher Line was designed under our supervision and that of Prof. Jenkin (whenever his duties in Edinburgh allowed him to come to London), in our own drawing office, by Mr. Archibald Elliott, an old pupil of Prof. Jenkin. It was erected in a studio in Fitzroy-street, and being seen there working by certain people interested in practical science, led to the formation of the Telpherage Company, whose function was to experiment on the plans of automatic electric transport suggested by Prof. Jenkin, Prof. Ayrton, and myself.

In that model Prof. Jenkin's first idea was employed of using what is called a "*Series System.*" This system is not the one which we are practically employing, but it will probably be immensely developed in the future. In Fig. 2 you will see

Fig. 2.

the principle of working. Figs. 3 shows a view of the locomotive, and Figs. 4 and 5 show an elevation and plan of the locomotive, train, and telpher line. In Fig. 3, A is the wire rope, gripped by the two wheels O and O, which are driven by the two little motors J and J. The two wheels, O and O, are pressed together by means of the levers L, L, and the springs shown in Fig. 5. There are grooved supporting wheels for the locomotive and the carriages, each carriage being like a pair of panniers, one hanging down

on each side of the rope. The rope is in sections of equal length, like A, B, C, D, &c., of Fig. 2. When there is no train on the line, all the sections are connected metallically together,

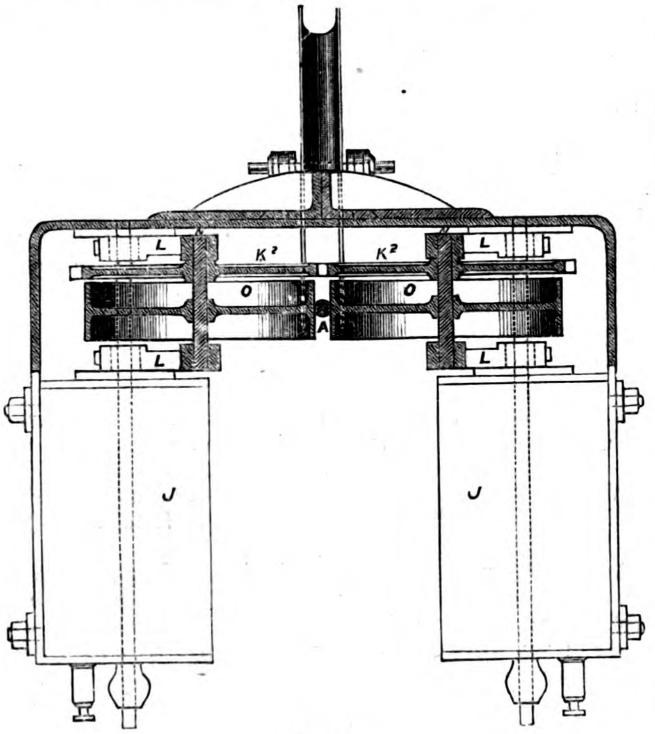

FIG. 3.

and form part of the circuit of a dynamo machine which is completed by the ground. But when the front of a train comes to the end of section A it touches a lever, which breaks the metallic connection between A and B. When the metallic

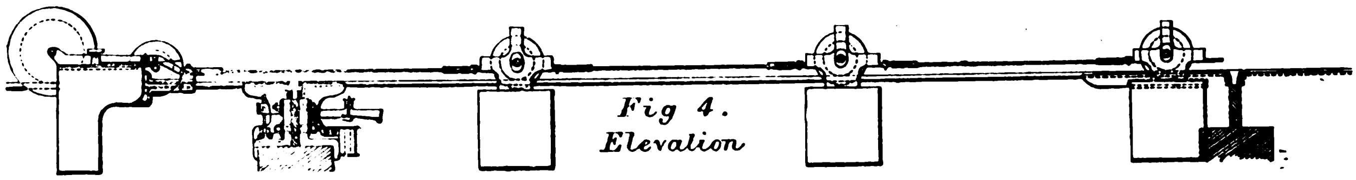

Fig 4.
Elevation

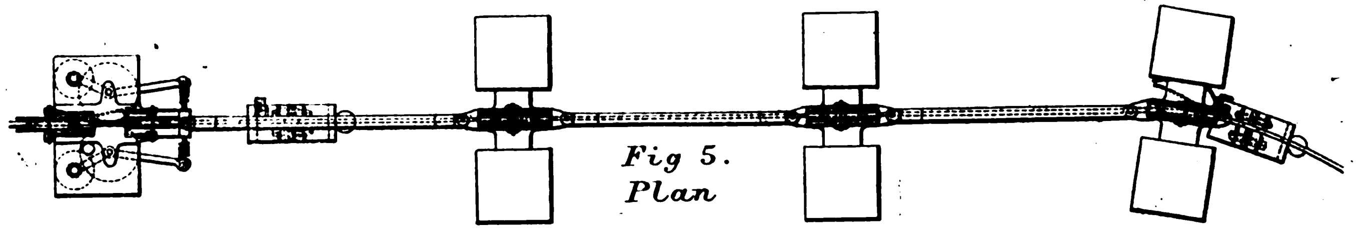

Fig 5.
Plan

connection is broken the current from the dynamo would cease to flow, but that a wheel on the front of the train touches B, and another behind touches A, and as these wheels are connected by means of two wires to the terminals of an electromotor, M, the circuit is completed through the train. And as a train is always bridging a gap, it continuously receives electric energy, and is propelled forward. The fore part of the train opens gaps, and the hind part closes them.

I am afraid that it would be impossible in one hour to give you, as I wish to do, a general idea of telpherage, if I now waited to describe in detail the block systems in use by us; but if you examine this model after the lecture you will readily understand, at any rate, one of the simplest of the dozen or more methods, differing in principle from one another, which we have described in our patents.

Until the formation of the company the great difference between the electrical methods of working of Prof. Jenkin and ourselves was in that he worked on a *series* principle, and we work on what is called the *parallel arc* principle—that is, the motors of his trains were all in one circuit, and the same current passed through them all; whereas we let each motor take its separate portion of the whole current, as incandescent lamps usually do in electric lighting. The diagram will explain the distinction. Fig. 6 shows the series system, and Fig. 7 shows the parallel system, A, B, C, &c., representing the motors, and X the dynamo. The series system can be

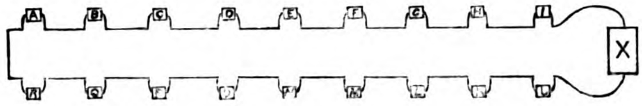

FIG. 6.

shown to be much more economical, and to be much simpler in the arrangements necessary for maintaining a constant speed; but it requires the use of motors which will take large currents, or else the use of dangerously high potentials in the conductors.

From the time of the formation of the company, we are sorry to say that, although the three inventors were to share

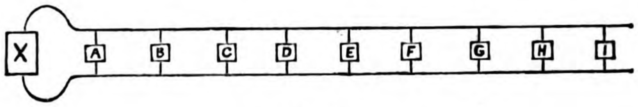

FIG. 7.

equally in any profits which might arise, they ceased to have equal shares in the credit of developing the system. It would be difficult to convey to a person who was not acquainted with Prof. Jenkin how hopeless it was to compete with him in the practical working out of an idea; and although, of course, much credit in working out the idea must be given to Mr. Jameson and the draughtsmen and other members of the Telpherage Company's staff, and to the directors of the company, and very greatly to the chairman of the company, on whose estate at Weston experiments on a working scale were entered upon immediately after the formation of the company, yet Prof. Jenkin was felt by every one to be the soul of the enterprise. Soon after those experiments commenced, he conceived a most marvellously simple method of working trains on a single line, which had not the disadvantage of the series system in requiring the train to strike an electric key, thus breaking the circuit at the head of every post. The practical objection to this striking of a key by the train had been so strongly felt by us, that my colleague and I had not only patented a great number of methods of contact making and blocking on our parallel system, but also on the Jenkin or series system. However useful these methods may turn out to be at a future time, their immediate necessity was completely done away with when the discovery was made by Prof. Jenkin of this "Cross-Over System," in which the trains are worked in parallel arc. The line is, as before, divided into sections, and sections A_1, A_3, A_5, A_7, &c., Fig. 8, are metallically connected together, and to one pole of the generator of electricity. Sections A_2, A_4, A_6, A_8, &c., are metallically connected together, and to the other pole of the generator. One of the

Digitized by Google

sets is of course well insulated from the other. Now the train is long, and there are two wheels on the train which are employed for making contact, and you will see that when wheel L (the leading wheel) is on what may be called the negative section A_2, wheel T (the trailing wheel) is on a positive section A_1, or when wheel L is on any positive section, wheel T must be on a negative section. The result is, then, that as the wheels L and T are electrically connected through a motor on the locomotive of a train, by means of a copper wire, which is insulated from all the other wheels of the train, the motor receives a supply of electric energy. Now, we saw last week that a motor runs always in the same direction whether or not the current that is made to pass through it may be reversed; it is only by altering the connections on the motor itself that we can cause it to run backwards; consequently whether wheel L be on a positive section and T on a negative, or T on a positive and L on a negative section, the train will be propelled forwards. You will see, too, that when an up line and a down line are required, the cost of metal in making the connections is very much lessened; for if the section A_1 is a positive section on the up line, the section B_2

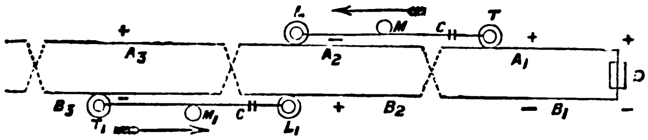

FIG. 8.

may be made a positive section on the down line, and the connecting wires are only 8ft. long, although the sections themselves may be 60 or 70ft. long.

This model shows the working of the cross over parallel system with an up and down line. [Model here shown.]

It is true that just as in Prof. Jenkin's first system, so in his new system, the sections into which his line is divided must be equal to one another, and this is sometimes inconvenient, as when broad gorges have to be crossed, and at curved parts of his line. But this difficulty can to some extent be overcome by employing what we call a *gravitation section* longer than the distance between the contact wheels of the train. This section is constructed with a downward slope, so that the weight of the train will propel it over the part in which it receives no electric energy. There is a defect in the cross over parallel telpher line which did not exist in the series system, viz., that at the end of every section the current passing through the motor is stopped and reversed.

The cross over parallel system is now at work at Glynde, in Sussex, and, as far as we know, our anticipations of success have been completely verified. Experience in the daily working of the line at Glynde has shown the necessity for the conductors of the motor having a higher insulation than usual, on account of the reversals of current, and this may cause us to introduce improvements which may to some extent diminish the simplicity of the system, which is at present very great. To give you an idea of how excessively simple it is, I will now show you a working model of a telpher line constructed in accordance with the first Ayrton and Perry patent. The plan consists in placing at intervals along the line, but not necessarily equal intervals, stationary brushes, or forks, or pulleys, all connected with the insulated terminal of the dynamo machine, and carrying a conductor on the train, which is always in contact with one or more of these brushes, or forks, or pulleys. Of course, the wire rope or steel rod which carries the train need not be insulated, and is the return conductor in connection with the other terminal of the dynamo. In this model you see that a copper wire hangs from the two ends of the train, and that no swinging can prevent the wire from falling into the forks, so that wherever the train may be on the line it will receive a supply of electric energy. This model before you shows how readily on this system a gorge may be crossed which is a great many times the length of the train, as the contact forks can readily be carried by the suspended rod. [The train was here run backwards and forwards along a span supported by two posts at a distance apart equal to ten times the length of the train.]

(To be continued.)

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The discussion upon Prof. Hughes's paper on "The Self-Induction in Electric Conductors" took place on Thursday evening, 11th inst., at Great George-street, Westminster. Sir CHARLES BRIGHT took the chair, the president, Prof. HUGHES, yielding that position during the discussion of his paper. Prof. HUGHES then offered a word or two of explanation in regard to Diagram 2 of his paper. The results shown were all for wires of 30 cm. length, which gave relatively the same E.M.F. for all currents.—Lord RAYLEIGH, in opening the discussion, expressed some doubt whether the definitions employed in the paper did not differ from those of Clerk Maxwell, a circumstance which threw some uncertainty in the way of discussing the facts scientifically. Also, as regards the ratio of the self-induction to the resistance, he questioned whether the difference in resistance of the various materials examined had been sufficiently taken into account. But there was no doubt that in several particulars Maxwell's theoretical expositions had now been confirmed by Hughes experimentally. Examining diagrammatically the method employed by Hughes, he, however, apprehended that there might be some danger of confusing the effects of induction with what were perhaps really due to resistance. These differing effects he thought were not certainly indicated by the Hughes instrument. Especially he could hardly conceive the self-induction of a stranded being less than a solid copper wire. If this were so, some of Clerk Maxwell's expositions would have to be reconsidered. Prof. Hughes's statements with regard to carbon were also novel, and would need further explanation. As a contribution to the subject in hand, Lord Rayleigh described some experiments of his own to determine the behaviour of iron and steel under very small magnetic forces. They were important as affording an explanation of the action of a telephone. He had found that its soft iron core in juxtaposition with a permanent magnet was precisely that condition most favourable to its sensibility to any disturbing effects; that is to say, its magnetic condition was considerably above that of the earth's magnetic force, but much below that of saturation.

Mr. FRANK POPE, editor of the New York *Electrician*, pointed out how the result of these investigations had satisfactorily explained several electrical phenomena which had long been a puzzle to practical telegraph-engineers in America. Notably the reason now given for the otherwise unintelligible fact that a lighting current would fuse a fine iron wire rather than take the course of a thick wire to earth. Secondly, it had long ago been observed, but nobody could give a reason for it, that working fast-speed instruments between New York and Philadelphia the speed obtained on a stranded wire was far in excess of that attainable on any other class of wire. A similar superiority had been noticed in the case of an iron wire which had a coating of copper. Prof. Hughes's experiments went to explain these peculiarities.

Prof. FORBES spoke in high terms of the paper, and confessed the great interest he had taken in the progress of these experiments. He then proceeded to indicate three important applications of the work of Prof. Hughes. The first point was the superiority of stranded wire to solid iron wire. The second point was in relation to lightning conductors, where Prof. Hughes has shown that the self-induction of a thick copper rod was so great as to cause the lightning preferably to come through the thin wire. This example of electro-magnetic momentum, he said, was analogous to the case of momentum in mechanics illustrated by the bursting of a gun whose muzzle is plugged with loose earth. The third point was in connection with submarine cables. For some years he had insisted upon the serious retardation produced by iron sheathing of cables, and he felt sure that Prof. Hughes's experiment would lead to the eventual abolition of this cause of retardation. Speaking of the theory relating to Prof. Hughes's experiment, he agreed with Lord Rayleigh in having some difficulty in understanding Prof. Hughes's terms. Lord Rayleigh had explained the application of the theory developed by Maxwell, but he (Prof. Forbes) thought there was something more. He showed that the E.M.F. of induction must be greater in the centres than in the outside of a wire, and consequently there may be sometimes a current in the centre of the wire contrary in direction to the main current, the outer part of the wire forming a short circuit to this induced current. The energy consumed by such an eddy current, or by the main current being confined to the outer parts of the wire, is in the nature of a resistance, and does not change sign with an increase or decrease of the current, as self-induction is generally supposed to do. This explains how Prof. Hughes obtained a different value for the resistance of a wire in the variable state, and in the stable state. He had applied this theory combined with the views put forward by Lord Rayleigh to all the experiments contained in Prof. Hughes's paper, and found that in every case the experiment was in accord with theory.

After a few remarks from Dr. HOPKINSON the discussion was again adjourned.

SCIENCE AND DEMOCRACY.

In the discussion which has followed the republication of Sir HENRY MAYNE'S remarkable essays on "Popular Government," our cousins on the other side of the Atlantic have taken a lively, if not very profound, interest; and one of them, Mr. E. L. GODKIN, of New York, has favoured us with the American view of the question in the current number of the *Nineteenth Century.* Mr. GODKIN'S case is argued with characteristic acuteness, and is so admirably written that whatever else may be charged to American Democracy it has plainly not altogether destroyed those qualities which favour the growth of first rate literary workmanship. Whether America is the "awful example" in some other directions which Sir HENRY MAYNE asserts it to be is quite another question, and one which we may safely leave him to fight out with his critics here and abroad. But on the point which particularly interests us, namely, whether the democracy is favourable to Science, as Mr. GODKIN contends it is, or hostile, as Sir HENRY MAYNE pronounces it, we think the American will get the worst of it. Not that his argument is any less incisive on this topic than on the rest; but his material falls far short of his needs. In fact, we suspect from the language he employs that he scarcely appreciates the real point at issue, simply through misunderstanding what Science really means. If we are right in this conjecture Mr. GODKIN is an instance of what he calls "passion for equality" having dulled the intellect against the apprehension of scientific truth. At all events, he makes it plain to us that a good deal of what passes for Science in the United States is what in England would be called charlatanism and the explanation he gives, so far from mending matters, only makes them worse; for it is a virtual confession that the People prefer what is at their own level, and are rather angry with Science for not coming down to it, which is pretty much what the English political essayist says about them. He could hardly say anything worse.

Recalling the Presidential Address at the last meeting of the British Association and the criticism it provoked, the warnings of Sir HENRY MAYNE and the admissions of his Democratic opponent are of interest to us just now. The recent appeal of the Royal Society to its members for additional funds to further the cause of independent research may be said to be on the old and safe lines of constitutional usage. One, though not perhaps the chief, aim of this Society is to benefit the people, whom, however, it neither consults nor invites to co-operation. But the endowment of Science for and by the people is a proposition obviously of quite another kind, more in accord with American notions than with those which have hitherto prevailed in the mother country. The idea is not, however, objectionable solely on that account. We have criticised it on its merits already. But in the light of Mr. GODKIN'S article some other grounds of objection and cause for misgivings are laid bare which are well worth considering. Sir HENRY MAYNE had pointed out as one of the evils of Democracy—meaning by that term a form of Government in which the popular element of numbers is predominent—that there always exists a "marked antagonism between democratic opinion and scientific truth," an antagonism which tends to develop into "the worst form of conservatism"—that is to say, the conservatism which rejects new revelations of science, whether in the sphere of philospby, politics, or religion, if they come in conflict with popular habits, prejudices, or beliefs.

Now, as regards this proposition, we suspect there are but few people in these islands who would take the trouble to gainsay it; most of us would, we imagine, accept the facts; and, if friendly to Democracy, might contend that they were not of sufficient gravity to affect the main question. We have seen enough of such popular hostility even here within the past half-century; nay, we are witnesses to a vehement outburst of it at this moment; and the only matter still in doubt is whether the people will enforce that "form of conservatism" if they have the power. But this is a question for English politicians. From America the answer is not encouraging, though Mr. GODKIN does his best to make it so. He begins by an admission which at once fills us with consternation. "No one can deny," says he, "that in regard to matters which can become the subject of legislation the American voter listens with extreme impatience to anything which has the air of instruction. . . . The passion for equality is one of the very strongest influences in American politics. . . . The orator [who addresses the Democracy on public questions] has to keep carefully, in outward seeming at least, on the same intellectual level as those whom he is addressing." And further on we gather that any political speaker who presumes to instruct his audience as to what opinions they should hold is contemptuously dismissed as an impertinent fraud. It would therefore seem that what Prof. HUXLEY in the same magazine ironically calls "the modern ideal of a leader of men," which is to stoop to be "a representative of *average opinion*," has been already fully realised in the American Democracy, and with results for Science which are rather depressing. Science, it is true, is listened to with more respectful attention than Politics can command; but when Science becomes the "subject of legislation," as, of course, it often ought to be, the American people look to their votes for inspiration and reject all external influence. The

Digitized by Google

doctrine that the bestowal of a vote confers all wisdom of the political sort is not new to us. We have now to learn, it appears, that it is equally efficacious in the domain of Science.

Mr. GODKIN gives a curious illustration of popular departure from orthodox Science in the fact that quacks and quack nostrums are popular in America to an extent, "the like of which can be seen nowhere else." His explanation is even more remarkable than the fact. It is due, he says, to popular "impatience with the caution and want of enterprise of the regular practitioners"; and the context shows that he thinks this a satisfactory account of the matter. Science is "cautious," and is therefore deserted for quackery; it lacks the characteristic "enterprise" of imposture, and has therefore only itself to blame. To be a leader of men in scientific as in political affairs the one thing needed is to represent "average opinion;" anything above the "intellectual level" of the multitude is an affront to their "passion for equality," and is therefore precluded in a general way from designing beneficial "subjects of legislation." The case of Mr. EDISON, who is cited as an example to the contrary, is, we fear, not altogether reassuring. After he had made some improvements in electric lighting and invented the phonograph he was "hailed as a man to whom any problem in physics—or physic? —would be simple. In fact, for a year or two he held the position of a 'medicine man,' to whom any mystery was easy." This is adduced as a "very good illustration of the respect of American people for the novel and the marvellous;" and nobody can doubt it. But it is no proof of their respect for Science. The Democracy, in short, although evidently a capital field for "medicine men," is not a very promising region for genuine scientists. We may hope the latter will not be discouraged in their pursuits; but we dare not predict that their discoveries will long be welcomed as "subjects of legislation" in the democratic era upon which we are now said to be entering.

ATLANTIC CABLES.

Two notes in our last issue require some explanation, inasmuch as they convey an impression which is altogether erroneous. The authority for the information given was from circulars issued by the Mackay-Bennett Cable Company, which appeared also in the *New York Herald*. As a matter of fact, the Atlantic cables of the Anglo-American, the Direct United States, the French, and the Western Union Companies were all efficient, and in as good working order at the time indicated as were the Mackay-Bennett cables. The land lines, however, of America had suffered from the stormy weather, and some of them were broken down. Still, there was no material interruption of traffic sent over the English cables. The statement that the communication between Europe and America "might have been entirely interrupted for many hours on the 29th ult. had it not been for the Mackay-Bennett Cable," was utterly at variance with the facts. With regard to the quick work, the time specified is so common and has been so frequently beaten that the other Atlantic Companies never thought of putting such a feat on "record." Hence, while the fact may be true as regards "the record," no special credit can be attached to the performance. With these arbitrage messages, it is almost a daily—we had nearly said hourly—experience to send a message from this side, or from the other, and receive the answer not only within six minutes, but often in less time. Our cousins are adepts in *double entendre*; they say one thing, leaving the hearer or reader to accept another meaning. The cables of the Mackay-Bennett Company are subject to the same laws and risks as other cables, and are not specially insured to remain intact while other cables fail. It may be taken as probable that the chances are somewhere about 45 to 1 that both the Mackay-Bennett cables are themselves broken rather than there should be a complete breakdown of the cables of the other companies.

CORRESPONDENCE.

RESISTANCE AS VELOCITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the subject of nomenclature is under discussion, may I take the opportunity of protesting against the loose mathematical diction often used, especially in connection with resistance? Because the change ratio of the electro-magnetic unit of resistance is $\left[\frac{L}{T}\right]$, people talk of a resistance of so many metres per second, which is an insult to common sense. It seems as if no one likes to protest against this loose mode of speaking, because it is sanctioned by so many eminent authorities. Sometimes we read that resistance is velocity; sometimes that it is homogeneous with velocity, or of the same order of nature as velocity; which appears to be a more verbose way of saying the same thing. Sometimes we read that resistance is *a* velocity, as if there were different kinds of velocity, resistance being, perhaps pink, "rotten-orange," or piebald velocity. It is odd that the use of "mixed" mathematics is not extended. We do not yet hear of this or that substance having a specific resistance of a quarter of an hour, or of a coil with a co-efficient of self-induction of a parasang.—Yours, &c., JAS. SWINBURNE.

Chelmsford.

ANIMAL ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observed your note in *The Electrician* of the 5th inst. respecting "Animal Electricity." I shall feel personally very much obliged if you or any of your correspondents can tell me what "animal electricity" is (practically), and its *modus operandi*. Can Mr. Barham tell me? If so he will confer a favour on—Yours, &c., PARALYSIS.

37, Park Cross-street, Leeds, Feb. 12th.

INSURANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am obliged for the answers to my letter which were published in your last issue.

From "R.I.S.K.'s" letter I gather that at least *one* other engaged in the electrical profession has received very strange treatment at the hands of an insurance company, and I think it is a pity that the name of the company was not published, so that it might save us the trouble of applying, in our ignorance, to them for protection. I say nothing of the want of knowledge on the part of the insurance company in refusing to accept the risks of electrical engineers.

It is some satisfaction, however, to find two letters from the manager and secretary respectively of insurance companies, stating that they are willing to take electrical engineers, but, it appears, on very different terms.

In the case of the Scottish Economic, we are placed in Class III., or "Hazardous" risks; but on inquiry at the Imperial Union Offices, in Finsbury-pavement, I find they are willing to accept *bonâ fide* electrical engineers on the same terms as civil engineers, in Class II. This company seems to have come to the sensible conclusion that the knowledge which electrical engineers have of the power of their machines and consequent danger (where any exists) tends to lessen their liability to accidents. It is, I believe, the same with civil engineers, for it must be confessed that they often have very dangerous work to perform in testing and examining bridges, foundations, machinery, &c., but owing to their *special*

Digitized by Google

knowledge of the dangers that exist they are considered as only liable to "medium risks."

I do not think it is necessary now to join together in order to take some concerted action, as "R.I.S.K." suggests, for to my mind the insurance question of electrical engineers is fairly solved by the information we have now gained that they will be accepted by one company at least as "medium risks," and classed with civil engineers.

My object having now been obtained, I beg to thank you for inserting my letter, and the other gentlemen who so readily answered it.—Yours, &c., INSURANCE.

London, E.C., Feb. 17, 1886.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My letter to you of 21st December last contained a statement of the fact that the boy did not feel a shock when he communicated one to another person. Dr. Stone took no notice of this in his first letter, but perpetrated the insinuation that I had been deceived, by his insinuating that the source of electricity was the action of the boy's feet on the carpet. In my letter of 9th January I especially recalled Dr. Stone's attention to the above-mentioned new fact, but no reply came from Dr. Stone. Instead thereof "Hamlet's" letter came, containing manifestly false statements with the intention of casting ridicule on the whole subject. In my letter of 30th January I gave the proof that it was impossible I could have been deceived (as insinuated by Dr. Stone and his shadow "Hamlet"), because my own faculties informed me that the electricity was not distributed over the surface of the boys' body, as it always was in my experience when I electrified persons by means of electricity from an external source. In Dr. Stone's letter of the 12th curt. he makes no reply to this proof, but proceeds to ridicule my statement that the air we breathe is a source of electricity within our bodies. His doing so only proves that he has not in his mind the facts wherewith to form an opinion on this subject. I shall therefore, with your leave, supply this defect.

The atmosphere we breathe consists of nitrogen, oxygen, and ozone, all of which contain their normal quantities of latent electricity, and when they enter the lungs they come in contact with the carbonaceous matter which consumes them. The internal heat of our bodies is thereby produced and kept up. Now, wherever there is combustion, the normal electricity contained in the bodies consumed is set free, and it takes up a new position by becoming latent either in the newly-combined substances, or it passes into the surrounding matter, as manifested in the flashes of lightning which often accompany the bursting forth of the great fires of volcanic eruptions. That which men and animals expire from their lungs is carbonic acid gas and the vapour of water. Here the question arises, Do these substances contain all the electricity which was taken into the lungs by the nitrogen, oxygen, and ozone inspired? If not, then a portion of the latent electricity of the nitrogen, oxygen, and ozone inspired must go into the blood and tissues of the body, and thence go to the skin and pass through it either as free electricity, like the lightning of the volcano, or become latent in the perspiration and pass off silently and unobserved by man.

In your notes of last week's number you drew attention, Sir, to the cases of the electric bug and electric cow. The particulars of the latter are contained in Volume V. of *The Electrician*, page 85. For my purpose I quote therefrom only the following facts:—"Mr. Woods, veterinary surgeon, at Wigan, was called, on 21st February, 1880, to examine a cow which had given birth to a calf, which circumstance had so deranged the cow's system that she had become charged with free electricity to such an extent that every person who touched her received a powerful shock of electricity. Mr. Woods administered to the cow powerful doses of opening medicine, and on the day following this all the appearances of free electricity disappeared from the cow's body." There is only one way in which this opening medicine could have had this effect, namely, by opening the pores in the cow's skin, and thereby restoring to her the power of perspiring in the normal manner, and then the electricity became latent in the perspiration, and was carried off insensibly.

The foregoing proof I consider sufficient for my present purpose, but, if necessary, I could give further proof that all the latent electricity carried with our breath into our lungs is not expired, and must find vent as free electricity on the surface of the skin, or disappear insensibly as latent electricity in the perspiration.—Yours, &c., JAMES JOHNSTONE.

8, Merchiston Park, Edinburgh, February 15th, 1886.

N.B.—In this letter I have used the word "latent" advisedly, because I have no sympathy with the delusion that electricity is "energy."

[We must endeavour to assure Mr. Johnstone that "Dr. Stone" and "Hamlet" are different individuals, unknown personally to each other, and resident the length of England apart. "Hamlet" assures us that he knew the man who exhibited the boy, and that electrical apparatus was used to produce the phenomena.—ED. *E.*]

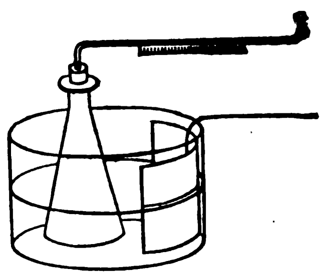
EVIDENCE RESPECTING THE REALITY OF "TRANSFER RESISTANCE" in ELECTROLYTIC CELLS.*

BY G. GORE, LL.D., F.R.S.

In a paper published in the *Proceedings* of the Royal Society, 1885, No. 236, Vol. 38, p. 209, I have stated that "a species of electric resistance, distinct from that of polarisation and ordinary conduction resistance, varying greatly in amount in different cases, exists at the surfaces of mutual contact of metals and liquids in electrolytic and voltaic cells," and "this resistance varies largely in amount with different metals in the same solution, and with the same metal in different solutions."

As conduction resistance is attended by evolution of heat, I took advantage of this fact to search for a difference of temperature produced by "transfer resistance" at the surfaces of different metals in the same solution, and I now employ the same fact in a somewhat different way to search for difference of heat evolved at the surface of the same metal in different liquids. I use an air thermometer instead of mercurial ones, and make an experiment like that of Peltier's, but employing a metal and electrolyte instead of two metals.

I took a thin platinum bottle, of a conical shape, of 10·0 cm. total height; 5·0 cm. in diameter at the bottom, and 1·25 cm. diameter at a height of 8·5 cm., at the bottom of the neck. It had a slightly concave bottom, and was placed in a flat-bottomed glass basin 12·0 cm. in diameter. It was closed air-tight by a perforated india-rubber bung, having a narrow horizontal glass tube, open at both ends, fixed in it. The tube had an internal diameter of about 2·0 mm.; it was provided with a small divided scale, and contained a minute drop of water to act as an index of the expansion or contraction of the enclosed air (see sketch).



After ballasting the bottle by means of a heavy ring of glass encircling its neck, the electrolyte was poured into the glass basin up to a height of 3·0 cm. A sheet of platinum 8·0 cm. × 15·5 cm. with its largest dimension horizontal, was placed vertically in the liquid to act as an anode. Under these circumstances, the amount of external surface of the platinum bottle in contact with the liquid, excluding that of the bottom,

* Read before the Royal Society January 21st, 1886.

Digitized by Google

was about 40·0 square centimetres, whilst that of the front side of the sheet of metal was about 46·5 sq. cm. These several conditions, and the distance of the sheet from the bottle, were kept the same in each experiment.

In some preliminary trials, using a current from a battery of six pairs of zinc and platinum in dilute sulphuric acid, in single series, and a large anode of zinc instead of the platinum one, on passing the current through a mixture of one volume of sulphuric acid and one hundred of water, into the bottle, whilst much hydrogen was evolved at the cathode, a small expansion of the air in the bottle at once occurred, and moved the index forward 1·0 mm. in about two or three seconds. The current was then stopped, and the index returned to its former position in about one minute. The piece of zinc was then replaced by a platinum wire which was brought into contact with the bottom of the bottle, and the circuit again closed. The current now circulating was about the same in strength as before, and none of it appeared to pass through the liquid; but notwithstanding no cooling influence by evolution of hydrogen now operated, there was no visible movement of the index or expansion of air in the bottle. This experiment of passing the current alternately through the liquid and through the bottle was repeated a number of times, and the same results respectively obtained. With nitric acid diluted in the same proportion, instead of the sulphuric acid, the effects were similar but a little more conspicuous, probably because the resistance was greater, and a portion of the hydrogen was oxidised.

As when the current passed through the liquid certain amounts of heat must have been absorbed by the liberation of hydrogen, and by that substance assuming the gaseous state, each at the surface of the bottle, and notwithstanding these cooling influences, the temperature of the bottle rose, an amount of heat more than sufficient to compensate for these losses must have been produced by the current. What was the source of this heat? Was it due to ordinary conduction resistance in the mass of the electrodes or liquid, or to some action at the surface of the bottle? As the index did not suddenly advance when the current was passed through the bottle only, the heat was not due to ordinary conduction-resistance of that vessel, and whatever the amount of heat produced by such resistance was, it must have been very small in comparison with that which produced the expansion. As the expansion was sudden, it could not have been due to resistance of any kind at the anode. And as the temperature of the bottle rose suddenly and fell quickly, and the mass and specific heat of the liquid were each considerable, it could not have been produced by heat of conduction-resistance of the liquid. The sudden expansion was therefore probably due to some influence, other than that of chemical change, acting at the surfaces of mutual contact of the liquid and bottle.

The influence of difference of liquid with currents of equal strength was also tried, the electrolytes consisting of (1st) a mixture of one volume of strong sulphuric acid and ten of water, and (2nd) of ordinary concentrated nitric acid for the purpose of preventing the evolution of free hydrogen. The current was from six Grove cells in single series, and its strength in each case was = ·454 ampere; it was stopped in each instance after a few seconds (whilst the expansion was increasing, though at a diminished rate), in order to exclude as much as possible the influence of heat of conduction-resistance of the liquid. The anode of sheet platinum was used in each case.

With the dilute sulphuric acid the expansion was = 3·0 mm. in two seconds, and on then stopping the current the contraction was 1·0 mm. in three seconds. Hydrogen was freely evolved. Increasing the density of the current by raising the bottle partly out of the liquid increased the rate of expansion, and decreased that of contraction.

With the strong nitric acid the expansion was 1·0 mm. in three seconds, and on then stopping the current a contraction occurred of about ·2 mm. in three seconds. No gas was evolved at the cathode. Increasing the density of the current in the above manner had but little effect. By passing the same strength of current up through the flask by means of a platinum wire in contact with the bottom of the bottle, an expansion of only ·5 mm. was produced in ten seconds.

The larger expansion with the dilute sulphuric acid than with the strong nitric acid, notwithstanding the cooling influence of the evolved and gaseous hydrogen in the former case, was probably due to a greater resistance of some kind at the surface of the bottle in the former than in the latter liquid. If this conclusion is correct, the heat produced by such resistance at the platinum cathode in dilute sulphuric acid was greater than that absorbed by the liberation and assumption of the gaseous state of the hydrogen in that liquid, and also greater than that evolved by such resistance in strong nitric acid. The small amount and slowness of expansion occurring when the current was passed up the flask, showed that the sudden expansion was not due to heat of conduction-resistance of that vessel.

In another experiment with dilute sulphuric acid, one volume of strong acid to ten of water, and a current of ·336 ampere, the expansion was 3.mm. in two seconds; and on then stopping the current, the contraction was 1·0 mm. in thirty seconds. And with nearly concentrated nitric acid, and a current of ·084 ampere, the expansion was 1·0 mm. in three seconds, and by then stopping the current, a trace of contraction in thirty seconds. Of course, in every one of the experiments, the amount of expansion shown by the index was less than the total, because the bottle itself expanded as well as the air in it.

If the sudden expansion in these cases was really due to some "resistance" at the surface of the bottle, it ought to vary directly with it. In order to test this point, the amounts of such "resistance" at the surface of the bottle when used as a cathode were carefully measured whilst a current of ·454 ampere was passing. That in the dilute sulphuric acid (one to ten) equalled 3·41 ohms; whilst that in the strong nitric acid was ·17 ohm, or $\frac{1}{20}$th the former amount. The amount of "resistance," therefore, at the surface of the bottle in the two liquids varied directly as the heat evolved and expansion produced. As the liquids were not stirred, the "resistances" measured included that due to polarisation, and its counter-electromotive force. As I had already in many cases found large differences of "resistance" at the surfaces of the same metal in different electrolytes, whilst the latter was being rapidly stirred in order to prevent polarisation, I did not repeat these experiments under the additional condition of stirring.

Separate experiments were carefully made to measure any alterations of temperature occurring in the mass of the liquids during the passage of the current of ·454 ampere through them, under exactly the above conditions; the thermometer employed being capable of indicating one-fiftieth of a centigrade degree. With the dilute sulphuric acid (1 to 10), and with the strong nitric acid, no perceptible alteration of temperature took place, even by continuing the current during three minutes. This fact agrees with the circumstance observed, that in each of these liquids, on stopping the current, the bottle cooled quickly; but had its heat been derived from the mass of the liquid this would not have happened. The absence of change of temperature in the dilute sulphuric acid is consistent with the inference that the heat produced by the resistance of the liquid, and that produced by surface "resistance" at the anode and cathode, and imparted to the liquid, was exactly neutralised by that absorbed by the chemical changes at the electrodes. In the strong nitric acid the circumstances were somewhat different, although the final result was similar. In that case, both the amount of heat of conduction-resistance of the liquid, and that of "resistance" at the electrodes was comparatively small, and the portion of heat absorbed by chemical action was also small, and these two quantities neutralised each other.

The surface "resistances" were measured by means of a Wheatstone slide-wire bridge, one terminal of a low resistance galvanometer being connected with the slider, and the other connected, first to the cathode and then to a platinum wire (idle electrode) close to the cathode, but not touching it, in the liquid; a balance being obtained in each case by moving the slider.

Additional Experiments.

In these further experiments the same arrangement and electrodes of platinum were used, and the temperature and

Digitized by Google

depth of liquid were the same as before, but the bottle was now employed as the anode.

With the mixture of one volume of sulphuric acid and ten of water, at atmospheric temperature as in the preceding experiments, and a current of ·454 ampere, an expansion of 1·0mm. in three seconds took place, and on then stopping the current a contraction of ·5mm. in five seconds occurred. The amount of surface-resistance at the anode, including that due to polarisation, was = 1·03 ohm. There was no perceptible rise of temperature during the ten minutes occupied in making these measurements. Much gas was of course set free at each electrode.

On comparing these results with those of the previous experiment in which the bottle was used as the cathode in this liquid, it may be perceived that the amount of expansion varied directly with that of surface-resistance, each being about three times greater with the bottle as the cathode than with it as the anode.

In another experiment, using the strong nitric acid, and the same strength of current, an expansion of 2·0 mm. took place in three seconds, and on then stopping the current, a contraction of 1·0 mm. occurred in five seconds. The amount of surface-resistance at the anode, including that due to polarisation, was = 1·4 ohm. Much gas was of course set free at the anode, but none at the cathode.

On comparing these results with the previous ones obtained with the bottle as a cathode in this liquid, the amount of expansion is again found to vary directly as that of surface-resistance. In this case, however, the resistance at the anode was considerably larger than that at the cathode; as with *very dilute* nitric acid I have found an opposite effect to this, it is probable that with a certain strength of acid the amounts of such resistance at the two electrodes would be equal; the dilute acid, however, was stirred.

Of course, when the object is to make measurements of all the elements of these phenomena we should have to consider the amounts of heat evolved and absorbed by chemical change and by alterations of physical state; differences of specific heat, changes of temperature caused by convection and conduction of heat, alterations of the amount of effective surface of the electrodes by accumulation of gas, conduction-resistance of the layer of liquid beneath the gas, and of the products of electrolysis adhering to the electrodes, the influence of polarisation, &c., and all this would require an extensive investigation; but in the present case, where only the general effect was sought, and the chief source of expansion was heat of surface-resistance, measurements of the smaller elements of the phenomena were unnecessary.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 274.)

*Korteweg's Theory.**

According to this theory, the forces between two elements of current are the same as in Stefan's theory. Korteweg, however, considers in addition the couples which one element may produce on another. If we use the notation we adopted in discussing Stefan's theory, we have, considering the force on ds_2, a force

$$\frac{1}{r^2}\left\{ a\,\alpha_1\,\alpha_2 + b\,\beta_1\,\beta_2 \right\}$$

along the line joining the elements, and a force

$$\frac{1}{r^2}\left\{ c\,\alpha_1\,\beta_2 + d\,\alpha_2\,\beta_1 \right\}$$

parallel to the axis of y.

In addition to these forces, Korteweg supposes that from the action of α_1 on β_2, there is a couple whose axis is parallel to the axis of z equal to

$$f\,\alpha_1\,\beta_2,$$

* "Crelle," XC., p. 49, 1881.

from the action of β_1 on α_2 there is a couple on α_2 whose axis is parallel to the axis of z, and equal to

$$g\,\beta_1\,\alpha_2,$$

and from the action of α_1 on γ_2, a couple on γ_2 whose axis is parallel to the axis of y, and equal to

$$-f\,\alpha_1\,\gamma_2;$$

and from the action of β_1 on γ_2, there is a couple on γ_2 whose axis is parallel to the line joining the elements, and equal to

$$h\,\beta_1\,\alpha_2.$$

If we now take arbitrary co-ordinate axes, the forces on the element ds_2 are the same as those given by Stefan's theory. The couples, however, are different; the component parallel to the axis of x of the couple on ds_2 is given by the equation

$$\begin{aligned} \mathrm{L} = \Bigg[& \frac{d}{r^2}\frac{dr}{ds_2}\left(y\frac{dz}{ds_1} - z\frac{dy}{ds_1}\right) - \frac{a-d-c}{r^3}\frac{dr}{ds_2}\frac{dr}{ds}(y^1z - z^1y) \\ & - \frac{b}{r^2}\frac{d^2r}{ds_1\,ds_2}(y^1z - z^1y) - \frac{c}{r^2}\frac{dr}{ds_1}\left(z\frac{dy^1}{ds_2} - y\frac{dz_1}{ds_2}\right) \\ & + \left(\frac{h+g}{r}\right)\frac{dr}{ds_1}\left\{ (y^1-y)\frac{dz_1}{ds_2} - (z^1-z)\frac{dy^1}{ds_2} \right\} \\ & + \frac{h-f}{r}\frac{dr}{ds_2}\left\{ (y^1-y)\frac{dz}{ds_1} - (z^1-z)\frac{dy}{ds_1} \right\} \\ & - h\left\{ \frac{dy^1}{ds_2}\frac{dz}{ds_1} - \frac{dy}{ds_1}\frac{dz}{ds_2} \right\} \Bigg] i\,i\,ds_1\,ds_2 \end{aligned}$$

with similar expressions for the components of couple around the axes of y and z.

By making the force between two closed circuits have the same value as that given by Ampère's theory, Korteweg finds that

$$a + 2b - d - c = -3\mathrm{A}^2$$

where A is a constant quantity whose value depends upon the unit of current adopted.

By making the couples produced by one closed circuit on another have the same value as that given by Ampère and the potential theory, he finds that

$$\frac{d}{dr}(r^2 h) + (g-h)\,r - c + 2\mathrm{A}^2 = 0.$$

Korteweg considers that the experiments of v. Ettingshausen, quoted above, prove (1) that the force on an element of circuit produced by a closed circuit is at right angles to the element, and (2) that the couple on an element due to a closed circuit has the value given by Ampère's theory; the first condition gives

$$c - b = 2\mathrm{A}^2,$$

the second, the two conditions

$$\frac{d}{dr}(rh) - f = 0$$

$$h + g = 0,$$

and he points out that we cannot get any more conditions by considering the action between two closed circuits or the action of a closed circuit on an element of another. It should be noticed that since, according to this theory, part of the action of one element of a circuit on another consists of a couple, the condition that the force due to a closed circuit on an element of another should be at right angles to the element is not, as in Stefan's theory, identical with the condition that the expression for the couple exerted by one closed circuit on another should be the same as that given by Ampère.

This theory is valuable because it is the most general one of the class we are considering which has been published. It is the only one which takes into account the couples, and by giving special values to the quantities a, b, c, d, f, g, h, we can get any of the other theories of this class.

On the theories which explain the action of currents by assuming that the forces between two electrified bodies depend upon the velocities and accelerations of the bodies.

According to these theories a body conveying an electric current contains equal quantities of positive and negative electricity, so that it will not exert any ordinary electrostatic

Digitized by Google

effect. The positive electricity is supposed, however, to be moving differently from the negative. In some of the theories (Weber's, Gauss's, Riemann's) Fechner's hypothesis, that the electric current consists of positive electricity moving in one direction (the direction of the current), and an equal quantity of negative electricity moving at the same speed in the opposite direction, is assumed; in other theories (Clausius') only one of the electricities is supposed to move, the other remains at rest. We see in a general way how the assumption that the forces between two electrified particles depend on the velocities and the acclerations of the particles can explain the effects produced by an electric current.

Let us take first the mechanical action between two circuits A and B, and let us consider the action of an element (a) of A on an element (b) of B. We shall consider first the action of the two electricities which are flowing through a on the positive electricity which is flowing through b. Since the motion of the positive electricity in a relative to that of the positive electricity in b is not the same as the motion of the negative electricity in a relative to that of the positive in b, the forces due to the positive and negative electricities in a will not counterbalance, so that there will be a resultant force on the positive electricity in b depending on the inequality between the motion of the positive and negative electricities in a relative to that of the positive in b. Similarly there will be a force on the negative electricity in b depending on the inequality between the velocities of the positive and negative electricities in a relative to that of the negative in b, and, except for special laws of force and special values of the velocities of the electricities in b, this force will not be equal and opposite to the force on the positive electricity in b, so that a mechanical force on b will be produced by the currents through a.

Let us now consider how inductive forces can be explained by this hypothesis; let us suppose that the element a is moving, and that the element b is at rest. The velocity of the electricity in a will be the resultant of the velocity with which the electricity flows through a and the velocity of translation of a itself, so that since the velocities of flow of the positive and negative electricities are different, the actual velocity of the positive electricity will differ in magnitude from the velocity of the negative (unless, assuming Fechner's hypothesis, the element a is moving at right angles to itself); thus the force due to the positive electricity in a on a unit of positive electricity at b will not be equal and opposite to that due to the negative electricity in a, and thus there will be an E.M.F. at b due to the motion of a. This explains induction due to the motion of the primary circuit.

Let us now consider induction due to the variation of the intensity of the current in the primary circuit. According to all the theories there is a force produced by a moving electrified body proportional to the first power of the acceleration of that body. Let us consider the elements a and b again, and suppose that a variable current is flowing through a and no current through b; then if we suppose that a variation in the intensity of a current is accompanied by an alteration in the velocity of flow, the acceleration of the positive electricity will, if we take Fechner's hypothesis, be equal and opposite to that of the negative; but since there is a part of the force due to the moving electrified body which changes sign both with the electrification and the acceleration, the force due to the acceleration of the positive electricity will be equal in all respects to that due to the acceleration of the negative, so that there will be a resultant force on a unit of positive electricity at b, and this force is the electromotive intensity at b due to the alteration of the intensity of the current in a. In this way we can explain the induction due to the variation of the current in the primary circuit.

Theories of this kind have been given by Gauss, Weber, Riemann, and Clausius, and these writers have given expressions for the force between two electrified particles moving in any way. We shall afterwards consider these expressions in detail, but we may remark in passing that the theories of Gauss, Weber, and Riemann have much in common; among other things they all lead to impossible results. In addition, Clausius has shown that, unless we make Fechner's hypothesis about a current, viz., that it consists of equal quantities of positive and negative electricity moving with equal speeds in opposite directions, a current would on these theories exert a force on an electrified body at rest.

The question of the forces due to moving electrified bodies is interesting in connection with electrolysis. Taking the ordinary view that the current is carried by the ions, we know from Hittorf's researches that the anion and the cation move at different rates, so that the forces produced by these will be different; hence we should expect an electrolyte conveying a current to exert a force on a charged particle at rest.

We shall now go on to consider the various theories separately.

*Gauss's Theory.**

Gauss assumes that the force between two particles separated by a distance r and charged with quantities of electricity e and e' is along the line joining the particles and equal to

$$\frac{ee'}{r^2}\left\{1+\frac{1}{c^2}\left\{u^2-\frac{3}{2}\left(\frac{dr}{dt}\right)^2\right\}\right\}$$

where u is the relative velocity of the two particles and c is a constant. This law will, if we make Fechner's hypothesis, explain the mechanical force between two circuits; but, since it contains no term depending on the acceleration, cannot explain the E.M.F. produced by the variation of the strength of the current in the primary; it is also inconsistent with the principle of conservation of energy, and so we need not consider it any further.

W. E. Weber's Theory.†

Weber assumes that the force between two charged particles, using the same notation as before is

$$\frac{ee'}{r^2}\left\{1+\frac{1}{c^2}\left(r\frac{d^2r}{dt^2}-\frac{1}{2}\left(\frac{dr}{dt}\right)^2\right)\right\}$$

This formula is not inconsistent with the principle of the conservation of energy; making Fechner's hypothesis, it will explain the mechanical force between circuits conveying currents; it will also explain induction due both to the motion of the primary and the alteration in the strength of the current in the primary. We shall, see, however, that it makes a body under certain circumstances behave as if its mass were negative—*i.e.*, if it were acted on by a force in a direction opposite to that in which it is moving, its velocity would continually increase.

Riemann's Theory.

This is explained in his "Schwere Electricität und Magnetismus," edited by Hallendorff, p. 327. According to this theory the force between two electrified bodies is not altogether along the line joining them, but consists of the following parts:—

1. A force along the line joining the particles equal with the same notation as before to

$$\frac{ee'}{r^2}\left\{1+\frac{u^2}{c^2}\right\}$$

2. A force on the first particle parallel to its velocity relative to the second equal to

$$-\frac{2ee'}{c^2r^2}u\frac{dr}{dt}.$$

3. A force on the first particle parallel to this acceleration relative to the second equal to

$$\frac{2ee'}{c^2r}f,$$

where f is the relative acceleration of the particles.

* Gauss's theory was published after his death in his collected works, Gottingen edition, Vol. V. p. 616. See also Maxwell's "Electricity and Magnetism," 2nd edit. Vol. II. p. 440.

† Weber's theory was published in 1846 in *Abhandlungen der Königlich-Sächsischen Gesellschaft der Wissenschaften*, 1846, p. 211; it is reprinted in *Electrodynamische Maassbestimmungen*, 1871. A good account of the theory is given in Maxwell's "Electricity and Magnetism," 2nd edit. Vol. II. Chap. XXIII.

Digitized by Google

There are, of course, similar forces acting on the second particles, and we see from the form of the expressions of the forces that the force on the first particle is equal and opposite to the force on the second. Riemann's law of force is not inconsistent with the principle of the conservation of energy, and it explains the mechanical force between two circuits ; hence it must explain the induction of currents. We shall see, however, that it is open to the same objection as Weber's theory, viz., that it makes an electrified particle under certain circumstances behave as if its mass were negative.

*Clausius' Theory.**

If x, y, z are the co-ordinates of the first electrified particle, x', y', z' those of the second, then according to this theory the x component of the force on the first particle is equal to

$$-ee'\left[\frac{d}{dx}\left\{(1-vv'\cos\epsilon/c^2)\frac{1}{r}\right\}-\frac{1}{c^2}\frac{d}{dt}\left(\frac{1}{r}\frac{dx'}{dt}\right)\right]$$

With similar expressions for the components parallel to y and z, here v and v' are the velocities of the first and second particles respectively, and ϵ is the angle between their directions of motion. We may analyse these forces a little differently, and say that the force on the first particle consists of—

1. A force along the line joining the particles equal to

$$\frac{ee'}{r^2}\left\{1-vv'\cos\epsilon/c^2\right\}$$

2. A force parallel to the velocity of the *second* particle and equal to

$$\frac{ee'}{c^2r^2}\frac{dr}{dt}v'.$$

3. A force parallel to the acceleration of the *second* particle equal to

$$-\frac{ee'}{c^2r}\frac{dv'}{dt}.$$

We have, of course, corresponding expressions for the force on the second particle.

Clausius's formulæ differ from those of Gauss, Weber, and Riemann in two very important respects.

1. They make the forces between. two electrified bodies depend on the absolute velocities and accelerations of the bodies, while the others make them depend only on the relative velocities and accelerations.

2. They do not make the forces between the bodies equal and opposite, so that the momentum of the system does not remain constant.

These results show that if this theory is true, we must take the ether surrounding the bodies into account. The first result can then be explained by supposing that the velocities which enter into the formulæ are the velocities of the bodies relatively to the ether at a considerable distance from the bodies, and the second result by supposing that the ether possesses a finite density, and that the momentum lost or gained by the bodies is added to or taken from the surrounding ether.

The case is analogous to the case of two spheres, A and B, moving an incompressible fluid ; in this case the forces on the sphere A depend on the velocities and acclerations of B relatively to the fluid a great distance from the sphere, and are independent of the velocity and acceleration of A ; the forces are not equal and opposite, and the momentum lost or gained by the system is added to or taken from the momentum of the fluid. At the end of this section we shall see that if we assume that variations in what Maxwell calls the electric displacement produce effects analogous to those produced by ordinary conduction currents, we get the same forces between moving electrified bodies as are given by Clausius's theory.

Clausius's theory is not inconsistent with the principle of the conservation of energy, and we shall see that it does not lead to the same difficulty as the theories of Weber and Riemann, viz., that under special circumstances a body would behave as if its mass were negative.

* This theory is given in "Crelle," Vol. 82, p. 85. There is also a full abstract in Wiedemann's *Beiblätter*, Vol. I. p. 145.

Assuming that in an electric current we have equal quantities of positive and negative electricity moving with different velocities, Clausius has shown in the paper already cited that his theory gives Ampère's results for the mechanical force between two circuits, and the usual expression for the induction due to the motion of the primary circuit, or variation in the strength of the current passing through it.

Fröhlich* urges against Clausius's law that since, according to it, an electric current in motion exerts an electromotive force on a moving electrified particle, even though the particle is moving at the same rate as the circuit, every current on the earth's surface ought to exert an electromotive force on an electrified particle relatively at rest, since each is moving with the velocity of the earth. This force is one that can be derived from a potential, so that the integral of the force taken round a closed curve would vanish, and thus, even if this result were true, two circuits would not induce current in each other if they were relatively at rest. Budde† points out, however, that the moving circuit would exert an electromotive force at each point of itself, and thus cause a separation of the electricity in the circuit, so that it would get coated with a distribution of electricity, the electrostatic action of which would balance that due to the action due to its motion on a point relatively at rest. The velocities which enter into Clausius's formulæ are velocities relative to the ether, so that if the ether moves with the earth, an electric current will, according even to this theory, exert no electromotive force on a point relatively at rest, and there will be no electrification on the surface of the circuit. The velocity c which occurs in all these theories is a velocity comparable with the velocity of light.

(To be continued.)

SOME POINTS IN ELECTRICAL DISTRIBUTION.‡

BY PROF. GEORGE FORBES, M.A., F.R.S.E.

When I had the honour, just a year ago, to give a course of Cantor Lectures to this society, on the distribution of electricity, the subject had not till then been treated in a systematic manner. I had then occasion to speak in strong terms of some of the methods then habitually adopted, and subsequent experience has confirmed me in the justness of my criticisms.

I gave a fairly complete account of the practical systems of laying electric mains, which were at the diposal of the engineer when designing a system of distribution ; but in the course of only three lectures it was impossible to do justice equally to all systems. When I was this year asked to give a lecture to the society, I eagerly availed myself of the opportunity to take up the straggling threads, and say a few words on the subjects which were previously but inadequately treated of.

Allow me to remind you that, in my lectures, I described five different ways of laying the mains, each one depending upon a different method of connecting the dynamo machines and lamps. Three of these may be called direct systems, and two indirect. Each system has special advantages when applied in suitable cases, and when an engineer is designing a scheme of distribution he carefully considers the *pros* and *cons* of each system as applied to the special case, and very often he has to go through the whole calculations of the scheme according to several different systems. And here let me repeat, what I have often stated before, that no amount of labour and expense in these preliminary calculations should be grudged, as the ultimate saving effected by the careful selection of a suitable and economical system may easily range to 100 per cent. or more on the total cost of the installation. The three direct systems are the parallel, series, and parallel-series methods of attaching lamps to the main conductors.§ The two indirect systems are with the use of secondary batteries and secondary generators. Each of these systems is capable of being varied in the details of its application, and each is specially applicable to particular cases. In a parallel system each lamp is attached by wires to the two main conductors, and thus to the two terminals of the dynamo. This is its characteristic feature, viz., that the lamps are all metalically connected with the terminals of the machines. In the series system, the conductor going through the district has its two ends connected one to each pole of the dynamo. But wherever there is a lamp the conductor is severed, and each terminal of the lamp is attached to one of the severed ends. In the parallel series arrangement the district is divided into sections. The first section and the last section have each a conductor attached to one terminal of the dynamo. The other conductor of the first section extends also through the second se-

§ In my Cantor Lectures I used the terms multiple arc, series, and multiple series. I prefer the terms now advocated.

Digitized by Google

tion but no farther. Another conductor extends through the second and third sections, another through the third and fourth, and so on. In each section the two wires from each lamp are attached to the two conductors of that section. The first or parallel system is generally most suitable for small installations ; but the cost of conductors becomes extravagant when the area is extended, except in very special cases. The series system is at present only used for arc lights, sometimes with the insertion of a few glow lamps to replace an arc lamp.

The third system is admirably suited in every case where the number of lamps in use at any time is constant, and may perhaps be modified so as to be applicable to other cases. Smaller conductors can be used on this system than on the first, and this effects a very great economy. Having recalled these points to your notice, I need say no more, as I treated these three systems and their modifications very fully in my Cantor Lectures.

I thought I had spoken strongly enough about the enormous cost of the main conductors, and the necessity for selecting that size of conductor which is the most economical. We must not use too small a conductor, for then the waste of energy in heating the conductors would be enormous. Nor must we use too large a conductor, for this means buried capital. We must select the size which balances one cause of loss against the other, so as to give the maximum economy. I find, however, that, while this axiom has been accepted as such in this country, some writers from America still try to uphold the fallacious views which have hitherto been in vogue there. I have noticed more than one criticism from America, by people asserting themselves to be connected in some way with some of the Edison companies, who protest against my statement that the three-wire system effects an economy of copper of only 25 per cent. over a two-wire system. The difference between us is that I start with the axiom that we are to use the most economical size of conductor. My critics start with the assumption that they shall use a conductor which shall waste exactly 10 per cent. of the energy. In this way they use a conductor which is not the most economical, and they show a saving of 62½ per cent. of copper over the two-wire system with a possible extra waste of energy of 62½ per cent. I said in my Cantor Lectures, and I repeat it this evening, that this manipulation of figures may suit American financiers, but it is not electrical engineering.

Before proceeding to discuss the indirect methods of distributing electricity, which is the main point I wish to touch upon to-night, I wish to supplement my remarks on series lighting by a statement of what has been done in the last year. I expressed a hope that more attention might be given to the lighting of houses by glow lamps in series. I further showed that it was only by means of a constant current flowing through glow lamps in series that the regulation of each lamp could possibly be effected on economical principles. This regulation must be accomplished by altering the length of the filament in the lamp. This has never yet been done, but if inventors once realise the importance of the object to be attained I feel sure that we shall not have long to wait for the solution of the problem. Now, I am delighted to be able to inform you that during the past year at least one inventor has been applying himself to the placing of glow lamps in series. Mr. Bernstein, who has paid so much attention to the system of glow lamps, has worked out the problem of using lamps of low pressure and large current in series. He has boldly taken extreme measures and proposes using lamps of 6 volts and 10 amperes, or even 2 volts and 30 amperes for larger houses. And here he has got over a difficulty I referred to in my Cantor Lectures. I said that there was no economical way of preventing a broken lamp from extinguishing all the others on the series. Passing part of the current through a shunt whose resistance is 100 times that of the lamp would be very expensive if we had in use lamps of the ordinary type, but with a lamp whose resistance is a fraction of an ohm, the expense would be trifling. When the lamp breaks, the current in the shunt is increased so as to release a contact which short-circuits both the lamp and the shunt. I still think, however, that the loss of energy by heat conduction at the terminals may be very great in lamps of so low a resistance ; Mr. Bernstein tells me it is 10 per cent. Still I can well foresee that, even if a very sensible loss of energy occurred, the economy and convenience of using such a system might be amply sufficient to warrant its adoption in many cases.

I congratulate Mr. Bernstein on his work in the past, and would urge him to develop this idea more fully, and I can assure him that I, for one, will give the fullest consideration to the system when preparing the plans for electric light installations. I should like also to take this opportunity of congratulating other makers of electrical appliances on the advances which have been made since the date of my Cantor Lectures. I should like especially to congratulate Mr. Swan on the improvements he has made in the manufacture of glow lamps ; the Messrs. Siemens and Messrs. Crompton on their successful construction of very large dynamos ; Messrs. Elwell and Parker on their great improvements in the details of construction of dynamos and motors ; and the Electrical Power and Storage Company on the continued improvements in their secondary batteries. I would equally congratulate Messrs. Willans and Crompton for the continued improvements in steam engine governors, for keeping the current from a dynamo or the pressure at any point in the circuit constant ; likewise Mr. Ferranti for having brought out an electric current meter which promises to fulfil all the wants of engineers and the public in this direction ; and last, but by no means least, Messrs. Woodhouse and Rawson for various new devices which will go far to assist in designing and carrying out many schemes of lighting ; and I would specially mention their automatic cut-out, adjustable to any strength of current, which, though not so new as some other devices, has only been brought prominently to my notice during the past year, and whose simplicity and reliability give me great confidence in employing it. I must not fail to include here, as a subject for congratulation, the rising esteem in which secondary generators are held, and the improvements which have been made in their manufacture. When I add to this list the admirable lampholder of Mr. Alfred Swan, Varley's adjustable carbon resistances, and other small but useful accessories, I think you will agree with me that the facilities at the disposal of the engineer for designing a satisfactory scheme of electric lighting, and which have been added to his store during the past year, are very abundant.

About some of these appliances I should like to add a few words.

First, I may say that the Electric Lighting Act was rendered abortive, if for no other reason, simply for the want of an electric current meter which was in all points satisfactory. In the year 1832 a patent was taken out for a meter in which the current passing round an electro-magnet created a field where mercury was placed, which rotated when the current passed through the mercury from the centre to the exterior of the field. If the magnetism be proportional to the current, and the friction be proportional to the square of the velocity, then the number of turns completed in any time is a direct measure of the total quantity of electricity which has flowed through the meter in that time. The marked improvements introduced into this meter by Mr. Ferranti consist in the perfection of the magnetic circuit, and the introduction of an almost frictionless mechanism for correcting the revolutions and showing them on dials like a gas meter.

I have many of these appliances on the table which any member of the audience may examine at the conclusion of the paper. In referring to my Cantor Lectures, let me make a few remarks about a double table which I introduced to assist engineers in calculating the size of mains required in any installation. These tables have been copied into a number of technical journals and books of reference, but in nearly every case there is no word of explanation how to use them. I have found these tables of such paramount convenience that I think it right to call attention to them once more. The economical size of main depends upon three variable factors—the price of laying down a ton of copper mains, the interest to be charged on the capital sunk in mains, and the value of an electrical horse-power for the number of hours that it is to be utilised during the year. My table is divided into two parts. Look along the line in the second part which relates to the percentage on capital which you propose to use, until you come to the column relating to that price of copper which you propose to use, and you then find a number printed which we may call the auxiliary number. Now take the first part of the table and look along the line which relates to that value of a year-horse-power which you propose to use, until you find the auxiliary number ; the heading of that column of figures tells you the size of main per 1,000 amperes which is most economical to use according to the data you have employed.

I will now remind you of the position in which we were left after a full discussion in the Cantor Lectures of the three direct systems of distribution. The parallel system, or the three-wire system, is admirably adapted in cases where the farthest lamp of the district is within two hundred yards of the central station. So soon as you go to greater distances the cost begins to increase in an alarming ratio. Hence this system would be applicable to a large district only by having engines and dynamos put down at a very large number of small stations. Now, a station is not worked economically unless the engine driver and stoker are fully employed, and the maximum economy cannot be reached with less than about 1,000 horse-power. Thus the parallel system is only applicable to cities so densely populated as to have a consumption of about 10,000 16 candle-power lamps in a radius of two hundred yards. But in most districts of this class space is valuable, and a large number of such stations would be very expensive. We must, then, in the parallel system of distribution, be content to work at a cost which is above that of the ideal of economy. There are many cases where the great simplicity of such a system does actually make it worth while to sacrifice this ideal of economy, and when an engineer is consulted on such matters, it is his duty to estimate the exact loss from not strictly following the ideal economical rules before adopting or rejecting this system. In order to make a parallel system effective, the central station must use distributing boxes, the methods of placing which are described in my Cantor Lectures. The cure for all these evils would be found if a thoroughly satisfactory system on the parallel-series plan were known. In that case high tension electricity might be used involving smaller conductors. Thus the central station might be at a distance, where land is cheap, and it might be of any size, so that all the works would be in the same place as they are in gas distribution. Here the only departure from the ideal of economy lies in the length of the conductors to the district which has the supply. But these conductors are comparatively small, and no engineer would recommend the adoption of such a system unless he found that the economy of having the works out of the expensive district exceeded the extra expense in mains.

Now I regret to be compelled to say that, after discussing all the ingenious plans on the parallel series systems proposed by Mr. Edison and others, I arrived at the conclusion that at this time there is no parallel series system of distribution which is quite satisfactory. I do not say that such a system cannot be devised, but I do say that at this moment no such system is available to the electrical engineer, except in the case where the same quantity of electrical energy is consumed in any district at all hours during which the current is being supplied. There are some cases where it will pay to insert equivalent resistances when lamps are put out. These cases are rare, but they must not be lost sight of by the engineer. Having in the Cantor Lectures discussed all the direct systems of distribution, I will complete my outline of this part of the engineer's profession by an examination of the two indirect methods which I formerly touched upon only lightly, viz., secondary batteries and secondary generators.

Secondary Batteries.—During the electric boom (as Americans would call it) of 1882, the secondary battery took a prominent part, not so much for what it had done as from what was expected it would do. It was said that since no one would think of sending gas from the retorts without storing it in a gasholder, so the same must be done with electricity. Every one will admit that it is most desirable that this should be done, and I am glad to say that secondary batteries have been improved to such an extent that there is every reason to hope that this will be done, always

Digitized by Google

provided that the companies who supply them do not expect the public to repay them for the hundreds of thousands of pounds which have been thrown away in the past. I have been given to test about a dozen different kinds of secondary batteries, of which I have found some four or five to be good, and the others mostly worthless. I can say this with certainty, that at the present moment secondary batteries can be supplied by certain makers which are to be relied on with careful usage, and which give us 70 to 80 per cent. return for the energy expended.

Now it might be asked what are the advantages of storing the energy if you lose 25 per cent. by doing so? The first advantage is that a breakdown in the machinery does not then interfere with the supply. The second advantage is that the steadiness of the supply does not depend upon the speed of moving machinery. The third and great economical advantage is that your expensive engines and dynamos are paying interest twenty-four hours of the day, instead of only a few hours, by doing their work; and a smaller supply of engines and dynamos suffices. Now this is all very well, so far as having secondary batteries at the point of supply is concerned, but it does not help us much so far in the great problem which we have attacked, viz., that of electrical distribution. But the improvement of secondary batteries led to great hopes of a cheap system of distribution. It was said, "Put your generating station at a distance, on cheap ground, carry a current with high potential through small conductors to the district to be lighted. Pass the current through some thousand accumulators in series, placing these in batches of fifty, say, each, in cellars, to light up a small district." The original idea was to keep the service wires permanently attached to the two ends of each set of fifty cells. Now, this plan is very beautiful if only it would work. But it will not work. The consumption being small from some of the cellars and large from others, and the same charging current going through all of them, the cells must become overcharged in many cases, and this is injurious or not economical.

Another plan was proposed, which I described in my Cantor Lectures. This was to introduce an arrangement to indicate when the cells were fully charged. By having two complete sets of batteries in each cellar, the indicator caused a rocking switch to act which switched the fully charged battery off from the charging mains on to the service mains, and at the same time switched the second set, which had, up to that time, been supplying the service mains on to the charging mains. Here I would point out that, independently of the fact that we have no reliable indicator to show when the cells are fully charged, this only moves the difficulty back one step. For it will often happen that both sets are fully charged, and yet we are obliged to send current through one of them. This plan was tried at Colchester, but of course it had to be abandoned. If we had a true indicator to show when the cells are fully charged, the more sensible plan of using it seems to be to cause the indicator to disconnect the cells from the charging mains and connect the charging mains metallically. There would of course be a great fall of potential in lamps immediately after switching off the supply current, but the charging of the cells might be done by day or after midnight, during which time lamps are not very much used. I think that even this small difficulty might be got over by causing the indicator when it acts to increase the number of cells which lead to the lamps. I suppose the most reliable indicators which could be used are those depending upon the specific gravity of the solution or the weight of the negative (oxydised) plate. Unfortunately it is seldom found that a number of cells working in series become charged at the same time. In fact, it is not very generally known that the most satisfactory plan for charging secondary batteries is to do so in quantity or parallel. When this is done, every cell is fully charged exactly at the same time, and all give off gas at the same moment. If there be any possibility of short-circuiting, however, fusible plugs or other cut-outs must be inserted.*

To have a thoroughly satisfactory installation, it is necessary that the cells may be left in their secluded retreats without attention for long periods. I think I can safely say that cells can be so left if fairly treated. But the question is whether any scheme of distribution hitherto considered does give them fair treatment. If attendants have to be continually going round to inspect cells, this expense must be carefully calculated so far as is possible, and taken into account.

Now let me say a few words as to the improvements in secondary batteries. First, I may say that there is now no doubt that they can be made, are made, by several makers of so good a construction that they can be used for years. I will not fix the number of years, because none of the most perfect ones have yet failed. Secondly, it seems to be conclusively proved that not only does no buckling take place, but there is no fluting or blistering if the plates are originally good, and if the air has has not been allowed to reach them. Thirdly, we know that in overcharging them we do not injure them, but merely waste current. These are important facts, and are all we want for an installation where the state of the cells can be always under examination. For central station lighting we want something more. We want the cells to take current from the dynamos when they require it. For this we must have an indicator on the cells to work a switch, according to the state of charge of the current. Up to the present no satisfactory master-cell has been devised. Those which depend on the gas given off do not act equally promptly with currents of different strength. The most promising system is one in which the state of the cell is shown by the specific gravity of the liquid. Very little ingenuity is required to develop this into a satisfactory system. But we cannot depend upon one master cell since it is only when charging in parallel that all cells act alike. If we have several master-cells in each battery, all of which must act together to cut off the dynamo, I think we might depend upon their action. The probable function of the switch is—first, when the E.M.F. of the battery is too high, to cut out the dynamo circuit from the battery, to give a through connection to the dynamo current, and to switch in two additional cells to the lamp circuit; second, when the E.M.F. of the battery is too low, to break the charging current, to connect the battery to it, and to cut off two cells from the lamp circuit. These are all ordinary things which can easily be done. If such a system were adopted there might be a question with the Board of Trade; but I should have no fear of the result if the work was properly carried out. At present if no better system is introduced we must use high tension currents. But even without automatic action of this sort there are many large installations where it would be economical to use secondary batteries even if attendants had to be continually examining the state of the cells. The engineer who is designing an installation, if he does his duty, calculates the cost of every method of working which can be feasible.

The cost is of course an important item, and were it not that this system introduces a great saving in copper conductors and machinery, it would often be too expensive to work. We may take the cost of batteries at about £3 per lamp of 60 watts. The saving in copper conductors is proportional to the number of batteries put in series. There is also a saving in dynamos and engines. If we take four hours as the average time of using the lamps, we charge them, say, for six hours in the day time, and we use the dynamos as well as the batteries during the greater part of the night. Thus we require batteries and dynamos for only about one-half of the number of lamps generally in use. This brings the cost of batteries down to £1. 10s. per lamp, and the cost of dynamos and engines from about £1 per lamp (the usual cost of a direct service) to 10s. per lamp. This makes a total cost of £2 per lamp, as against £1 by a direct service. When we have made a further reduction for diminished size of conductors, and an increase for additional attendance, we are in a position to compare the two systems. But these figures vary so enormously, that it is impossible to estimate them, unless one has the details before him. We may say safely, however, that in large districts there would be economy in secondary batteries, and in small districts in a direct service. But the advantage of not being dependent on the constant perfection of machinery is very great, and avoids the necessity for so complete a duplication of the parts. Of course, the cost of working must also be made out, allowing for a loss of at least 20 per cent. in transforming through the secondary batteries.

The number of ways of using secondary batteries is great, but there are no engineering difficulties in the distribution, and I may, therefore, content myself with having drawn attention to the general advantages of using them. Among the many special appliances used in this kind of work, I am glad to be able to show you some useful things supplied by the Electrical Power and Storage Company. Perhaps the most important of these is a switch for large currents, in which a number of concentric tubes have a longitudinal slot into which the arm of the switch is forced. The split tubes have a certain amount of spring and literally cut into the arm of the switch, and so make good metallic contact. The one before you has been thoroughly tested with 1,500 amperes passing through it. Another appliance is an automatic switch to reduce the number of cells in the lamp circuit when the dynamo is charging the cells and *vice versâ*. A third is a cut-out to prevent damage to the charging dynamo by an accidental falling off of speed. It has this peculiarity, that it puts the battery in circuit again so soon as the dynamo resumes its functions.

In concluding this part of my subject, I would draw your attention to the scheme of connections for the Vienna Opera House. The dynamos are by Messrs. Crompton, of 72,000 watts, and are driven by direct acting Willans and Robinson engines. I am told that they give an electrical horse-power for 3·7lb. of coal. The secondary batteries are supplied by the Electrical Power and Storage Company. The three-wire system is adopted, 110 cells are ordinarily in use with each circuit, and six additional ones are available to keep the electric pressure constant.

(To be continued.)

LEGAL.

In the Chancery Division on Saturday last Mr. Justice Pearson made an order for the winding up of the British Electric Light Company. The counsel engaged were Mr. M. Cookson, Q.C., and Mr. Ryland for the petitioners; Mr. J. Joyce for the company.

On Wednesday, before Mr. Justice Pearson, Mr. RYLANDS said: I apply *ex parte* for the appointment of a provisional liquidator of the British Electric Light Company. Your lordship made an order for the winding up of this Company on Saturday; but previous to that order being made the landlord had put in a distress for rent, and he has now prepared to sell the effects of the Company to-morrow (Thursday). Under those circumstances it is thought advisable that a provisional liquidator should be appointed, with power to pay the landlord the amount of rent due, if he sees fit. The arrears of rent amount to over £200. The Company consents to this application, and it is considered that it would be the best arrangement for all the creditors.

The JUDGE: I cannot do what you ask.

Mr. RYLANDS: Then will your lordship grant me an interim injunction to prevent the landlord from selling the chattels of the Company?

The JUDGE: Yes; I will grant an injunction restraining him from selling or taking any steps under the distress; and will give you leave to give short notice of motion for Friday.

An order was also made on Saturday, on the application of Mr. N. Lawrence, to continue under the supervision of the Court the voluntary winding up of the International Electric Company.

* Even in this case we may have a partial short circuit, which will drain the current and yet will not cut out the cell.

COMPANIES' MEETINGS.

Submarine Telegraph Company.

A meeting of the proprietors of this Company was held on Tuesday last, at the offices of the Company, 2, Throgmorton-avenue, London Wall, under the presidency of Sir Julian Goldsmid, Bart., M.P.

The SECRETARY (Mr. S. M. Clare) having read the notice calling the meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said that he thought the shareholders would say that, on the whole, the report was a satisfactory one. If they had read it, they would have seen in the first place, that, in consequence of the improved condition, especially of the Dutch cables belonging to the Government which they would remember were either partially or completely renewed not along ago, they had had very few breakages in their cables, and the result had been that their ship had been at home for the greater part of the year, and the curious fact resulted from this circumstance that the drawback which was allowed by the insurance office was in excess of the premium they had had to pay, consequently they had paid nothing at all for the insurance of their steamer, and they had a small balance in their favour which would go over to the next half-year's account. In that respect they had nothing to complain of. They had had to repair the Dieppe cable, having had to put into it something over three miles and a half of new line, and they had also had to put one mile and a quarter into the Salcombe cable, which constituted the really important business with regard to repairs that they had had to do, and as both had to be done about the same time, their ship had to leave port only once. He thought this was a matter of congratulation. But when he came to other points he was not quite satisfied. He had told them for some time past what was the condition of their affairs with regard to traffic. He had pointed out that they had had a steady increase in it, and a steady falling off in the length of the messages. He found that whereas for the half-year ended 31st December, 1884, the year before they had 1,428,520 messages. These had increased for the half year ending 31st December, 1885, to 1,490,871, and the words had increased from 17,007,776 in the previous year to 17,062,135 in the year ending December 31st, 1885. The average length of the messages, which was 11·91 words in 1884, had now decreased to 11·44 words, showing that the system of compressing messages was still going on. He had often said, and he repented it now, that he could not tell where the limit of fall in this respect might be. Of course, there was one somewhere, but they had not been able to ascertain it, and he noticed in the returns, with regard to the month of January, which he had been examining, that there was a still further decline from that average of 11·44 words. This was an unsatisfactory side of the question, and he had always thought it his duty to put before the shareholders all the information upon the subject that he reasonably could do, in order that they might have the same advantages as the Directors themselves. It would be observed also that in the report they referred to the Telegraph Conference at Berlin, and he would like to say on behalf of the Board that they considered that Mr. De Bunsen represented their interests at that Conference with great ability. That gentleman belonged to a family of diplomatists who had done a variety of public services, and the Company were very fortunate in having so able a man to represent it as Mr. De Bunsen, for he had done the work extremely well. The alterations in the International scale were comparatively small, and would come into force only on the 1st July next, and would certainly not injure the Company much because the difference which would be created would be very small indeed. He thought this was the sum and substance of their affairs. They had lost one newspaper; but the *Daily News* had leased a wire of three hours a night, in the same way that other papers were in the habit of doing, showing that it was an enormous advantage to the Press to be able to use a wire for their own particular purposes for a certain period during the night. The Submarine Company, therefore, assisted in that way materially to spread information over the whole world. He thought altogether the state of their affairs was satisfactory, and the dividend they were able to recommend a good one, all circumstances considered.

The Right Hon. ROBERT BOURKE, M.P., seconded the motion.

The CHAIRMAN, in reply to a shareholder, said that the Liverpool merchants would have liked to have a special wire—in fact, a special cable laid—to carry their own messages. But two or three years ago the Company and the Post Office investigated the matter, and it was clearly proved that the traffic which the Liverpool merchants afforded was extremely small, and not likely to be enough to remunerate a special wire or cable. As far as any complaint on the part of these gentlemen was ever made, it arose in connection with delays in the land lines and not in the Submarine Company. He was quite certain of this, that if Liverpool could give sufficient business for a special wire, the Company would be quite prepared to co-operate with the Post Office in giving it. He remembered also that some complaint of the same kind was mentioned to them by some of the German authorities, and the Board handed to them the carefully prepared papers on the subject, which were very complete, with the result that those authorities thought the answer so conclusive that they took no further notice of the matter.

The motion was then carried unanimously.

The CHAIRMAN next moved, "That, in accordance with the recommendation of the Court of Directors, a dividend for the half-year ending 31st December, 1885, at the rate of $14\frac{1}{2}$ per cent. per annum, less income-tax, on the capital of the Company, be now declared to become payable on and after the 1st of March next."

The Hon. ASHLEY PONSONBY seconded the motion, which was unanimously adopted, and a vote of thanks having been passed to the Chairman and Directors the proceedings terminated.

The India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The twenty-second ordinary general meeting of this Company was held at the Cannon-street Hotel on the 18th inst., under the presidency of Mr. Wm. J. Tyler.

The SECRETARY (Mr. S. W. Silver) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I will at once proceed to move the adoption of the report, and in doing so I think I may allude to what was done on the occasion of our last meeting. It is a great pleasure to us to meet under such circumstances as we have the opportunity of doing to-day. We at our last meeting alluded to the issue of new shares, and I think we may each congratulate ourselves upon the result. The fact of your having supplied us with additional sinews of war will in a measure account for the satisfactory state of things which I hope you feel, with me, we have the opportunity of putting before you to-day. The operations of the year will, I am sure, bear comparison with any undertaking of a similar character. You must bear in mind that competition on all sides is so strong that our difficulty in getting orders is very great, and our difficulty in getting orders to leave anything like a margin of profit is still greater. I do not think I need go into the question of figures, and detain you in so doing. These are a proof of the labours and the close attention on all sides to the interests of the Company. I think they show very fairly as compared with previous years. The result of our net profits this year is within a very little of last year, leaving a disposable balance of £137,547, which, of course, includes the premium upon the new shares, which, as you see by our report, is passed to the reserve fund. After deducting the dividend of £41,000, which is £1 per share, we have a balance to carry forward about the same as last year. As regards the work done, we have connected Cape de Verde with the West Coast of Africa, and sold that cable to the Eastern and Brazilian Companies. We have connected the Portugese and French possessions on the coast of Africa to the extent of 600 miles, and the remaining portion is in process of manufacture, and will be laid towards the close of the year. Now, that is under a guarantee from Portugal of £42,000, and a subsidy from France of £12,000, and a traffic almost half as much as these two amounts together. Besides this, we have manufactured for the Government Indo-European Telegraph Department upwards of 500 miles. Our steamers conveyed the cable to the Persian Gulf, and by their own officers, headed by Sir Henry Mance, that cable has been laid most satisfactorily, our own people being present under the direction of Mr. Theophilus Smith. The whole of this operation has been referred to already in *The Times* of the 25th of last month. I allude to that because it really gives a very satisfactory account of the whole proceeding, and as I think you will agree with me we are not in the habit of blowing our own trumpet, we have in that a very satisfactory report of the manufacture of the cable and of the *employés* connected with the India Rubber Company, as well as the state of our ships. We have executed other orders for the Post Office, India Office, the Western Union Company, and the Western and Brazilian Company, so that in the cable department we have been fairly occupied. With respect to the general state of the works, I may say that electric lighting has not been overlooked by us. Should the time come for a general demand for that most delightful adjunct to our households, we are quite prepared to meet it, and that means that our works are in very excellent order. We are in a position now, I may say, to complete an Atlantic cable under six months—making and laying—and for your satisfaction I may tell you that that item of expenditure upon the works may now be considered to be closed. It will not, I think, be added to much further. Now, all this means that much care and attention have been given by our manager, and by each member of our staff, to the work. This has not been brought about without a great deal of anxious and unceasing care and attention, and at once I am brought to the fact that I occupy the chair to-day in place of one to know whom was to respect him —the late Mr. George Henderson. I fully endorse the words which the report gives utterance to. I may add a little to that by saying that his attention was unceasing. In our anxiety to fill his place we have persuaded Mr. Matthew Gray to take a seat at the Board. (Applause.) I was sure that that would meet with your approval. In him I may say we have the lever, and to him we may attribute much of our success, not only as regards the works—the processes of manufacture—but also in the selection of the *employés* his judgment has been proved again and again to be excellent. Our thanks are certainly due to the members of the staff, and I must not pass over my excellent friend, Mr. Hutchins, our solicitor, whose advice and counsel we have great reason to be thankful for. I do not think I ought to overlook the fact that in laying these cables—the preparation for doing so, the soundings, and so on—Mr. Robert Kaye Gray, Mr. Buchannan, and others on board our steamer, lost no opportunity of adding to the works on physical submarine geography. The reports published by the Government refer especially to the work of the "Dacia," and they are worthy of your notice. At Oxford the other day, in conversation with Prof. Mosley, whose name stands very high in the scientific world, I was very glad to hear that the work was fully recognised, as I know it was, in the hydrographer's office. With these observations I will now move: "That the report and accounts now presented be received and adopted, and that a dividend of £1 per share, free of income-tax, payable on and after the 19th inst., be now declared."

Mr. NEIL BANNATYNE seconded the motion.

Mr. DIXIE referred with deep regret to the death of Mr. Henderson, testifying to the services which that gentleman rendered to the Company. He moved the following resolution: — "That this meeting, having read, with sincere regret, the paragraph in

Digitized by Google

the report announcing the death of Mr. George Henderson, desires to express its high appreciation of his personal character and worth, the uniform courtesy and consideration which distinguished him as a Director and Chairman for more than twenty years, and the strenuous efforts made by him in the interests of the Company which have contributed so largely to its development and present success; and this meeting further desires to express its cordial sympathy with his colleagues, and requests that a special message of condolence may be conveyed through the secretary to the widow and members of his family, with a copy of this resolution."

Dr. D. H. SMALL seconded the motion, and said that although he was not always at one with the late Mr. Henderson, he could fully acquiesce in the resolution. He knew that in times of difficulty Mr. Henderson had even made himself personally liable on the part of the Company in connection with money matters.

The CHAIRMAN then put this motion which was carried unanimously.

Mr. SUTCLIFFE wished to know if it was according to the Articles of Association that the Directors should receive 10 per cent. upon the profits in addition to the sum of £2,000. The report must be very satisfactory to every shareholder, and he hoped that the success of the Company would continue, but at the same time it seemed to him that they were paying an excessive amount to the Directors. According to the balance-sheet, the Board received £4,700 or £4,800, giving to each member about £1,200, and he supposed the Managing Director had remuneration besides. It appeared to him that there was a great deal of property invested with continental nations which were not in the highest credit, and he saw that they had received interest from the Spanish National Submarine Telegraph Company of £7,734. He presumed that the capital on which they had received that interest was probably £100,000.

Mr. ANSON referred to the resolution which he proposed a few years ago, regarding the remuneration of the Directors, and stated that the resolution was carried unanimously. He thought it was just that the remuneration of the Board should proceed *pari passu* with the success of the Company—that was, if it were not successful the Directors would receive only so much, while if it were successful they would participate further in that success. They paid the Directors well, and the result of that was seen in the report before them.

Mr. CATLEY asked the value at which the various steamers stood.

Mr. COCHRANE said that some years ago they decided to establish a building as a sort of institute at Silvertown for the workpeople. It was very much desired, and he wished to know what had been done in the matter.

The CHAIRMAN: Mr. Sutcliffe's remarks, as far as the remuneration of the Directors goes, I think, have in a great measure been answered by Mr. Anson; but if you like to have the resolution that was passed read, the secretary will do so.

The SECRETARY read the resolution, and stated that it was passed on the 9th of February, 1881, and was as follows:—"That for the year 1881 and thereafter, subject to revision by the shareholders in general meeting, the ordinary remuneration of the Directors should be £2,000 per annum, and that whenever the shareholders shall receive a dividend of 10 per cent. per annum or more the Directors shall be entitled to receive, by way of additional remuneration, 10 per cent. upon the net profits shown in the accounts for the year in excess of £31,200, being the amount required to pay such a 10 per cent. dividend, but in no year shall the Directors' remuneration exceed £5,000."

Mr. SUTCLIFFE stated that the amount was now considerably more than £31,200.

The CHAIRMAN: So much the worse for the Board; it is spread over a wider surface. I take it now that that is so far answered. As to the reference to the investments—Spanish and Portuguese—we are looking to English companies. The fact that Mr. Sutcliffe alluded to as to the Spanish National Telegraph Company is an answer that the amounts are being paid off regularly, and that line is paying its expenses. To the West Coast of Africa Company that will be a great feeder, and ultimately there will be a very satisfactory return, I believe.

Mr. GRAY said, in reply to Mr. Catley, that the value of the steamers now stood on the books at about 40 per cent. less than they cost, speaking roughly. For instance, one vessel had cost them £115,000, and it stood at £50,000; another cost £45,000, and stood at £30,000, and another had cost £32,000, and stood at £20,000. He therefore thought they were in a pretty healthy condition as far as the value of the steamers was concerned. With regard to the remarks of Mr. Cochrane relative to the proposed institute, he quite endorsed them. All the detailed drawings had been prepared, and the land was ready to receive the building when they were in a position to commence operations. The reason they had not done so before was that they had been so very busy in the erection of their own works, which had required all their attention. The matter, however, had not by any means been lost sight of, and they would proceed with it as soon as they possibly could.

The CHAIRMAN then put the motion for the adoption of the report and accounts, and the payment of the dividend, and it was carried unanimously.

Mr. HENDERSON then acknowledged in feeling terms the resolution of condolence which had been passed in memory of his father.

On the motion of Mr. ABRAHAM SCOTT, seconded by Mr. MATTHEW GRAY, the retiring Directors, Mr. Silver and Mr. Bannatyne, were re-elected.

Mr. KELSO afterwards proposed, and Mr. SINCLAIR seconded a resolution for the re-election of Mr. Weise as auditor of the Company.

An extraordinary meeting was subsequently held, at which the following resolutions were passed *seriatim*, on the motion of the CHAIRMAN, seconded by Mr. BANNATYNE:—

"1. The Board of Directors may from time to time appoint one of their number or any other person to be a Managing Director of the Company, and may determine the amount of his remuneration and the terms of his engagement, but no such engagement shall be for a longer period than five years. A Managing Director shall not retire from office by rotation during the period of his engagement."

"2. The number of Directors (including any Managing Director) shall not exceed seven nor be less than four, and every Director shall hold at least 100 shares in his own name as the sole holder thereof. The Directors may from time to time appoint any additional Directors or Director, provided the number of Directors shall never exceed seven."

"3. The remuneration of the Directors other than a Managing Director shall be from time to time determined by the members at the ordinary meeting; but any proposal for the alteration of the remuneration of Directors shall be deemed special business, requiring seven days' notice to be given thereof."

"4. The Directors may from time to time sell, lease, exchange, or otherwise dispose of and deal with all or any parts or part of the property of the Company situated in France upon such terms and in such manner as they may think expedient."

The CHAIRMAN stated, in answer to remarks and questions, that in future the report should be sent to the shareholders fourteen days before the meeting was held. It was not proposed by the third resolution to make any alteration in the system under which the Directors were at present remunerated.

A vote of thanks was then passed to the Chairman and Directors.

The CHAIRMAN, in reply, said: In the name of my co-Directors and self I beg to thank you for the kind manner in which the resolution has been proposed and responded to. Already I have referred to the attention given by the Board to the affairs of the Company; but I have great satisfaction in including my friend Mr. Gray in that vote. Upon our shoulders much of the credit due to him has fallen. Accept our thanks and assurance that our attention to your interest will not in the least slacken, and we hope to meet again in twelve months with as satisfactory an account as we have on the present occasion rendered to you.

The proceedings then terminated.

BUSINESS NOTICE.—Messrs. Elliott Brothers inform us that the premises, at 449, Strand, which they have occupied for so many years past, are required for other purposes on the 25th March next, and that their whole business of optical, mathematical, and electrical instrument makers, &c., will be carried on from that date at their manufactory, 101 and 102, St. Martin's-lane, Charing-cross, W.C.

NOTES.

MERCURY.—It is reported from Odessa that very rich and extensive quicksilver mines have been discovered in the basin of the Donetz.

ERDITE.—An American company is now manufacturing filaments for incandescent lamps of a new material called "erdite," a metalloid.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 19th inst. amounted to £3,241.

A CAT BATTERY.—There was a very funny article in last week's issue of *Illustrated Bits* on the cat as a galvanic element. It was entitled the "Cat Battery."

PRIVATE BILLS IN PARLIAMENT.—A petition was presented last week against the West London Electric Lighting Bill, from the Strand District Board of Works.

OBITUARY.—We regret to hear of the death of Mr. C. W. Hutchinson, B.S.C., Postmaster-General of Madras. Mr. Hutchinson died on the 30th ultimo at the age of 52 years.

TELPHERAGE.—On Monday last Professor W. E. Ayrton delivered a lecture at the Midland Institute, Birmingham, on "Telpherage; or the Automatic Electric Transport of Goods and Passengers."

THE PROFIT ON MICROPHONES —Some one figures out that in ten years the instruments, which cost the Bell Telephone Company $3·42, have each yielded a gross revenue of $178·74.

LECTURE.—On Monday evening Mr. W. J. Lancaster delivered a lecture at the Public Hall in connection with the Leamington Institute, on "Electricity, Past, Present, and Future."

THE SS. "GREAT NORTHERN."—This vessel left England about a month ago for Zanzibar, where she will be stationed as the Eastern and South African Telegraph Company's repairing steamer.

VICTORIA, AUSTRALIA.—A Reuter's telegram dated, Melbourne, February 22nd, announces the appointment of the Hon. F. T. Derham to the office of Postmaster-General in the newly-formed Coalition Ministry.

NEW ZEALAND.—The local press of New Zealand generally strongly supports the action of the Government in reference to the New Zealand cable reduced tariff, and advocates the laying of a second cable rather than a ten years' contract.

THE TELEPHONE IN BELGIUM.—The contract for the establishment and exploitation of a telephone system in the town of Termonde will be let on the 24th of March, and not on the 24th of February, as previously announced.

ROSCOBIE.—A series of popular lectures for young men are being given at the above place. At a meeting which was held last week Mr. Farquhar intimated that he had arranged for an early lecture on electricity by the Rev. W. Oldham.

ELECTRICAL RAILWAYS.—It is computed that there are now in the world about 13 electrical railways; the total mileage of 40·8. This we should say is underestimated. The longest line is that between Geneva and Saint Julien, a distance of about 10 miles.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 19th inst. were £2,560, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CORRECTION.—By a singular accident, the Essays on "Popular Government" referred to in our leading article last week was described as being the work of Sir Henry Mayne. Of course, the book in question is the one recently published by Sir Henry Maine.

ITALY.—Messrs. Armington and Sims have received an order for a number of additional engines from the Italian Government, to be used for electric lighting purposes in Milan. This order will make twenty engines of this company's manufacture in use in Italy.

TELEGRAPHS.—From recent statistics it would appear that during the past year about 2,500 telegraph offices were opened in different parts of the world. Among these may be mentioned six towns in Bolivia, ten in China, four in Corea, six in Paraguay, and four in Persia, &c.

NEW PUBLICATIONS.—There is about to be published by M. A. Lefevre, of Brussels, a work entitled "Concours International de Traction Mécanique et de Matériel de Tramways," being the report of a special international jury of the Antwerp Exhibition. The price is moderate.

PRIVATE CARRIAGE LIGHTING.—Many private carriages are now lighted in Paris by electricity. The lamps are connected with small accumulators placed under the driver's seat, being removed and charged with electricity from a dynamo during the daytime, for use at night.

THE MINER'S LAMP.—Mr. J. W. Swan has been giving an exposition of his new electric safety mining lamp to the members of the Glasgow Philosophical Society. The paper was substantially the same as that lately read in Newcastle, and its author received a cordial vote of thanks.

SOCIETE BELGE D'ELECTRICIENS.—This society is occupying itself with a discussion on the following subjects:—Fundamental principles of electricity, measures, batteries, dynamos, transformers, storage cells, lamps, electric lighting, distribution of electrical energy, and the telegraph and telephone.

SINGAPORE.—We are informed that a very successful subscription fancy dress ball took place at the Singapore Town Hall early in January. A notable feature in connection with the ball was the employment of the electric light in lighting the Town Hall, the entrance hall being brilliantly illuminated under the direction of Mr. Wells.

OVERHEAD TELEPHONE WIRE IN AMERICA.—Reports from St. John, New Brunswick, state that the wires all over the country continue to suffer severely from the late hard weather and heavy snow. Bad reports come from the Dominion. At St. John, New Brunswick, out of 170 miles of telephone wire in operation, not more than 25 miles were left on the poles.

TELEGRAPH CLERKS.—A largely-attended meeting of the second-class clerks of the Central Telegraph Office was held on Wednesday evening, at the Foresters' Hall, Clerkenwell, to consider their position and prospects. Amongst the resolutions passed was one expressing sympathy with the provincial telegraph clerks on their not receiving payment for Sunday duty.

LAYING SUBMARINE CABLES.—We should like to know how it is, when submarine telegraph cables are laid close in shore, where cross-bearings and sights can be readily obtained, their position cannot be more correctly laid down on the charts. It not unfrequently happens that an error is introduced varying between three-quarters of a mile and five or six miles.

THE TELEGRAPH BATTALION.—A piece of plate has been presented to the Royal Engineers officers' mess, South Camp, Aldershot, by the officers of the Telegraph Battalion, who

Digitized by Google

were recently employed on active service on the Nile at Suakim, and in Bechuanaland. The piece is a tazza of Spanish workmanship, and is set with a large number of exquisitely cut cameos.

LONG DISTANCE TELEPHONY.—The Vienna correspondent of the *Standard* reports that the telephone trials between Brünn and Vienna, which commenced on Wednesday, are being continued with completely successful results. The ordinary telegraph wire was used, without interruption of the service, and the words were not only audible, but the speaker's voice could be distinguished.

ABERDEEN.—The Education Committee of Gordon's College have resolved to proceed at once with the lighting of the east wing of Gordon's College by electricity, and to accept the estimates of Messrs. Menzies and M'Whirter for the supply of a dynamo and the necessary leading wires, lamps, and fittings; and arrangements have been made to have the work, as far as possible, executed during the ensuing vacation.

TOWN LIGHTING.—We notice that tenders are invited, and will be received until 1st April, 1886, for lighting the city of Asheville, North Carolina, with electricity or gas. The lighting area is about 1½ mile square, and the population 6,000. Tenders are also asked for by the City Council of the City of Freeport, Illinois, for the lighting of the city with electric lights, for the term of one to five years, from the 1st day of May, 1886.

TELEGRAMS AT THE ROYAL COURTS OF JUSTICE.—In order to expedite the transmission of telegrams to the Royal Courts of Justice, the superintendent, Mr. Hantler, has, with the sanction of the Lord Chancellor, made arrangements with the postal authorities, whereby all telegrams will be wired direct to that building, instead of to the Fleet-street office as hitherto, and will be at once delivered by messengers attached to the telegraph office in the courts.

THE ELECTRIC LIGHT IN AMERICA.—There is, says a contemporary, little ground for surprise at the progress made by the electric light in America when the price paid for gas is considered. A list of the prices per thousand cubic feet shows that the lowest price charged is 4s., namely, at Baltimore, Pittsburg, and Chicago. From this price it ranges up to 16s. at Galveston and San Antonio, Texas. The most usual price is 10s., and an average may be taken at 8s.

THE MECHANICAL TELEPHONE.—A writer in the *Electrical World* comes to the conclusion that enough has been already accomplished and practically demonstrated to place the success of the mechanical telephone beyond cavil, and is of opinion that its rapid adoption by railway corporations and private individuals is indisputable evidence of its growing popularity. We, on the other hand, are of the opinion that the mechanical telephone has a more limited sphere of operation than is indicated by our contemporary.

FOLKESTONE EXHIBITION.—The contract for the lighting of the Folkestone Exhibition has been given to the Electrical Power Storage Company. There will be 1,250 incandescent lamps for the lighting of the picture galleries, which will be supplied from two Crompton shunt-wound dynamos and two sets of E.P.S. batteries. The central nave, refreshment room, gardens, &c., will be lit by 36 Crompton arc lamps of 3,000 candle-power, the necessary power being obtained from two 30 horse-power Marshall engines.

A DISASTROUS EXPERIMENT.—An American exchange says that Harry Worman, a bright boy of Fostoria, Ohio, according to a report from that place, showed so much interest in electrical experiments that he became a privileged character at the electric light works, no other outsider being permitted near the dynamos. The other day he wanted to receive a "good shock," and so got a pail of water and, touching the positive pole of a dynamo with a rod in one hand, put the other hand in the water, and fell back dead.

THE INDIAN NATIONAL TELEGRAPHIC UNION.—It is announced that the Indian National Telegraphic Union is now in full working order. Sufficient funds have been collected; local committees have been organised at the principal stations throughout India, which will keep the committee here informed about current events within their respective limits; and telegrams are now being regularly despatched, giving the English public information about important events in India, and about the Indian view regarding such events.

THE SLAMMOPHONE.—A Pittsburg paper says that an instrument, called by its maker the "slammophone" (probably from the Greek *slammus*, to bang the door, and *phonos*, to make a noise !), is attached to the door of the Clarke studio, Oakland. The slammophone, which is something like an Æolian harp, is fastened against the door in such a way that a series of pendent hammers strike the strings when the door is opened or closed. The coming or departing guest is therefore greeted by a concourse of sweet sounds of his own making, and, until informed, cannot for the life of him tell where the weird music comes from.

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—From the report of this company it appears that the accounts for the year show a net profit of £82,740. 15s. 8d., to which must be added £72,166. 8s. 7d. brought forward, making a total of £154,907. 4s. 3d. From this amount is deducted the interim dividend of 5 per cent., leaving £132,497 4s. 3d. to be dealt with, out of which the directors propose to distribute a dividend of £1. 16s. per share, making, with the amount already paid, a total for the year of £2. 8s. per share, or 20 per cent., free of income-tax, leaving £65,267 4s. 3d. to be carried forward.

ELECTRIC LIGHT IN FIFE.—On Monday night a number of spectators were attracted to the harbour to witness the first exhibition of the electric light which had been seen in the locality. A new Norwegian steamer, the "Faerder," arrived from Christiansand on Sunday evening with a few passengers and a cargo for Burntisland and Grangemouth. In order to complete the discharge of the Burntisland portion on Monday night, the electric light, with which the vessel is furnished, was employed. Two lamps were suspended from the masts fore and aft, the dynamo being worked by an engine of seven horse-power. The illumination proved of great convenience.

"PRIMERS OF ELECTRICITY."—For the information of many of our foreign subscribers who have asked the question, we may say that the "Primers of Electricity," while being of an elementary character, are intended for the use of students of electricity rather than the general public. Besides a variety of useful and clearly written explanations of almost every kind of electrical apparatus and machinery, the little work contains a few eminently practical papers on submarine cable engineering. We would especially commend these latter to the notice of the *employés* of cable companies. They will find them invaluable in conjunction with a text book such as Kemp's.

THE DELIVERY OF TELEGRAMS.—In the House of Commons on Monday night Mr. Henry Fowler, in reply to Mr. A. B. Forwood, said it was the opinion of the Post Office that an address which was sufficient for a letter was not sufficient for a telegram. A letter bearing an efficient address in all proba-

Digitized by Google

bility fell into the hands of a postman who had letters to deliver to the same person almost every day; whereas a telegram was delivered by a messenger who might never have heard before of the person to whom it was addressed. What the department required in the case of a telegram was that the address should be sufficient to enable the messenger to find the person without delay.

ELECTRICALLY OPERATED FLUSH TANK.—The *Sanitary Engineer* says that Mr. D. W. Hyde, of Boston, Mass., has invented an interesting novelty in flushing apparatus. He has contrived by means of an electric current, such as is used ordinarily on electric call bells, to relieve the weighted end of a lever and thereby to lift a valve in a tank, which is closed automatically and the lever placed in position to again be dropped on touching a button located anywhere. If desired, it can be arranged to trip the lever at intervals, making a tank with an automatic intermittent flush, and a switch can be arranged so that at any time it can be changed to be operated, at the will of the user, by the push button.

THE LIGHTING AT ROCHE-SAN-FORON (HAUTE SAVOIL).—In this installation the water supply is taken advantage of. A fall of 17 metres is utilised to drive a Girard turbine of 45 horse-power, which in turn actuates a Thury H_1 dynamo, giving 150 amperes, with a mean difference of potential at the terminals of 110 volts, at a velocity of 600 revolutions per minute. An uncovered copper cable 4 kilometres long and of a mean section of 240 mm^2 is used in the installation, but the supply leads are on the Berthoud-Borel system. The lamps are the Edison of 10, 16, and 32 candle-power. When in full work the distribution amounts to about 22 electrical horse-power, or, roughly speaking, to 250 lamps of 16 candle-power.

ELECTRICAL FIRE ALARMS.—On the 23rd inst. Mr. W. L. Carpenter made an interesting contribution to the weekly series of Penny Science Lectures in progress at the Victoria Hall and Coffee Tavern. The subject was that of American electrical fire alarms. Remarking at the outset of his lecture that on the outbreak of a fire the first five minutes were worth the next five hours in respect of the efforts made to extinguish it, Mr. Carpenter pointed out that on the American continent this fact had been far more thoroughly appreciated than in the old world. In London and in Glasgow public fire alarms were only used in a few isolated cases, whereas in the great cities of America they formed part of a large and important system.

NOT ALL ON ONE SIDE.—The gas journals make such capital out of an occasional accident to a dynamo that we may be excused for departing for once from our usual rule of observing silence on the subject of the numerous disadvantages of gas lighting. The following paragraph will show that the complaints which have been urged against the electric light are equally applicable to the more malodorous luminant:—"The town of Deal was suddenly plunged into darkness on Wednesday through an accident at the gas works. The incident caused the greatest confusion, and being a dark night the main thoroughfares for some considerable time presented a singular spectacle, the tradesmen, in the general confusion, hastening to close their premises."

THE ELECTRIC LIGHT IN PARIS.—From further advices we learn that the installation in the Artillery workshops at Saint-Thomas-d'Aquin, will consist of 2 Gramme lamps of 300 candle-power, and 82 incandescents, of which 2 are of 25 candle-power, and the remainder of 10 candle-power. These will light the workshops only. In addition each workman will have a 10 candle-power lamp for his own use. The current is supplied by 2 Gramme dynamos giving 50 amperes with a difference of potential of 70 volts. The installation has been put down by Messrs. Buchin, Tricoche and Co. The Rochechouart public baths are now electrically lighted. This installation comprises 12 Edison incandescents of 20 candle-power, and 20 Street and Macquaire arc lamps.

THE ELECTRIC LIGHT IN AUSTRIA.—A contemporary reports that an installation of 250 lamps of 16 candle-power has just been completed by a Vienna firm at the hunting seat of the Emperor of Austria in the Zoological Gardens at Lainz, including 120 lamps of 25 candles each for lighting the road about 2¼ miles in length. There are four dynamos driven by a twin engine working normally up to 35 horse-power. Two dynamos light the buildings, to which place the wires are well protected and laid underground; they are made up into lead cables enclosed in tubes of prepared wood, or into cables embedded in the best asphalte and contained in solid wooden boxes. The lamps are placed on the two sides of the road, and are joined in series; each side being lighted by a separate dynamo. These lamps are fixed on posts and the connections are made with an uncovered copper wire from post to post.

TELEPHONIC LITIGATION.—We announced recently that writs had been served by the United Telephone Company upon Mr. Wilfrid Fleming, of Liverpool, for alleged infringement of Bell's and Edison's telephone patents, and we ventured to remark that, as the only instruments which Mr. Fleming had been selling and erecting were the valve transmitter (Prof. Silvanus Thompson's patent) and the English mechanic receiver we doubted whether any serious attack was intended, especially as the new telephone company was known to be prepared to guarantee Mr. Fleming against the attack of the United Company. Our forecast is likely to be justified by the event, as we have the very best means of knowing that affidavits have been filed by the manager and by the solicitors of the United Telephone Company, the effect of which is to withdraw from the attack so far as the new telephone company's instruments are concerned.

CHESS BY TELEPHONE.—Two games of chess were played a few days ago between members of the Manchester and Liverpool Chess Clubs, assembled in their respective club-rooms, which are forty miles apart. Communications were carried on by telephone. The Lancashire and Cheshire Telephone Company had made special arrangements by which the players could converse with as much certainty of being understood as if they were seated in the same room on opposite sides of the chessboard. Non-players had also opportunities of hearing the verbal messages which passed to and fro, and some found entertainment in the strains of the Theatre Royal orchestra, which trespassed on the same wire and could be heard in a subdued form. Much satisfaction was expressed with the working of the telephone, all the moves—over thirty on each side in one game and about forty in the other—being transmitted without a single mistake.

INDIAN TELEGRAPH DEPARTMENT.—In the House of Commons on Monday night Mr. Conybeare asked the Under Secretary for India whether it was the fact that the complaints of the officers of the Telegraph Department in the Government of India in respect of absence of promotion had been long admitted by the Government of India to be well-founded; whether any and what steps had been or were about to be taken to remedy their grievances; and whether he would communicate with the Government of India with a view of laying before Parliament at an early date all the papers relating to the subject. Sir U. Kay-Shuttleworth said the fact that there are grounds for complaint had been admitted,

Digitized by Google

and was the subject of correspondence with the Government of India, with the hope of increasing the efficiency of the department and remedying all just grievances. As soon as possible information would be given to Parliament.

BIRMINGHAM.—A contemporary says:—"The meeting of the British Association, fixed to take place in Birmingham on 1st September, will be the fourth that has been held in that town, the dates of previous meetings there being 1838, 1849, and 1865. Following the precedent set on these occasions, it has been arranged to hold, concurrently with the meeting, an Industrial Exhibition of the local manufactures. This Exhibition, which will be open from 26th August to 1st October, however, is to be on a scale of completeness not previously attempted. The manufactures of Birmingham and the surrounding districts, within a circuit of 15 miles, will be fully represented, and in most cases processes will be shown, or at least clearly indicated. The trades represented will be engineering, hardware, heating and lighting, arms and ammunition, jewellery, glass and pottery, stationery, leather, furniture and decoration, with a section devoted to scientific and musical instruments.

THE TELEMICROPHONE.—Under this title M. Mercadier has designed an instrument which combines the properties of the microphone with those of the telephone. The following is a method of construction recently described by the inventor. To the diaphragm of an Arsonval telephone are fixed, after being enclosed in a cylinder of thin iron, the carbons of an Arsonval and Bert microphone. These carbons are in the interior of the apparatus, and the pressure they exercise upon their support is regulated by a small auxiliary magnet. The electrical connections are the same as those in an ordinary microphone. When the diaphragm receives a sound wave it vibrates and produces two simultaneous effects, *i.e.*, a microphonic effect in the primary circuit of the coil, by reason of the movements of the carbons fixed to the diaphragm, and a telephonic effect by reason of the movements of the diaphragm in the field of the magnet. The instrument is intended to be used as both a transmitter and a receiver.

FIRE AT A TELEGRAPH WORKS.—On Saturday morning, at half-past ten o'clock, the fire brigades at Woolwich and Greenwich were called to the very extensive telegraph apparatus works of Messrs. Siemens and Co., in Harrington-road, Woolwich. The firemen found that an occurrence of a serious and alarming character had happened in a one-floor building used for the preparation of gutta percha for telegraph wires. It would appear that, with a tremendous report, a still exploded with great violence, and the melted substance spread all over the building, and soon caught fire. Without delay two of the private hydrants fitted to the place were got to work, but the burning matter flowed into the yard and set fire to the stock. For a time the fire burned with great strength, and appeared of a very threatening character, but the firemen eventually succeeded in subduing the outbreak. Serious damage, however, was caused by the fire and explosion to the building and its contents, as well as to the contents in the yard.

ELECTRICITY AND MEDICINE.—At a recent meeting of the French Academy of Medicine, M. Brondel read a paper on the introduction of certain medicines into the system by means of electricity. If the electric current is made to pass through a solution of a salt, the salt is decomposed, the metallic base passing to the negative pole, and the acid, or metalloid, to the positive pole. The iodides are easily decomposed by electricity. In order to introduce iodine into the system, a rubber plate, moistened with a solution of iodide of potassium, is placed upon the surface of the body. Over this plate the negative pole of a battery is applied, while the positive pole is placed upon a part of the body toward which it is desired that the iodine should travel. The iodine separates from the potassium, which remains at the negative pole, and passes with great rapidity through the tissues towards the positive pole. This may be demonstrated by testing with a starched paper, which becomes blue. A great number of substances can thus be made to traverse the tissues, and the applications of this discovery are numerous and important.

LIGHTING OF LONDON BANKS.—The Electrical Power Storage Company have just completed an installation at the Bank of New South Wales, Old Broad-street, E.C., consisting of about forty lamps of Woodhouse and Rawson manufacture, supplied by a Crompton dynamo, and a set of thirty-one of the E.P.S. cells, type 15 L., in glass boxes. The engine is a 3½ h.-p. Otto, and the special arrangements made enable the machinery to be run at any time in the day without the slightest noise being heard either in the Bank itself or in the neighbouring premises. It will be remembered that this company have an installation at the Bank of England, which has worked throughout most successfully, and we are informed that the same set of cells has been in use since the installation started, more than two years ago, without being renewed in any way. The company are also engaged in fitting up the new premises of the English Bank of Rio Janeiro, in Moorgate-street, on the same system, and there is no doubt that other banks will adopt the light now that it has been shown that the gas engine need not cause inconvenience if the proper precautions are adopted.

TESTS OF INCANDESCENT LAMPS.—From an account of some further experiments carried out by Mr. Peukert at the Upper Technical School, Hanover, with a number of incandescent lamps by various makers we extract the following:—The Siemens and Halske 98-volt incandescent lamps took a current of 0·554 ampere. The mean temperature observed was equivalent to a radiation of about 35·7 calories per hour. The candle-power of the lamp in air was 8·8. The Edison 93·6-volt lamps required 0·963 ampere. The mean temperature was 55·26 calories per hour and the candle-power 16·9 in air. The Swan 76-volt lamps required 2·55 amperes. The temperature was 124·19 calories per hour and the candle-power 30·0 in air. Expressing in calories the work of the current we get the following particulars:—With the Siemens and Halske lamps the total work of the current per hour appears as 46·98, of which 11·28 calories only were converted into light. With the Edison, the total work being 78·01, the energy appearing as light was 22·75. With the Swan lamps, of a total of 167·86 calories 43·67 were absorbed for light.

THE NORTHERN DISTRICT TELEPHONE COMPANY.—This company, we are told, are very busy just now with their various trunk lines, particularly that between Hartlepool and Stockton, while all the preparations for completing the trunk between Sunderland and Hartlepool are now in order, and the work will be proceeded with at once. In this district winter is again having an innings, and during the past week there has been every conceivable kind of weather. Snow has been falling during the last day or two; but though it is in its most destructive condition as far as overhead wires are concerned, namely, soft, and what schoolboys call "binding," none of the wires have suffered. The pantomime, laid on from the Theatre Royal, Newcastle, has been a great source of amusement to the subscribers at Sunderland lately, but the quaintest effect was produced a short time ago at an evening party, where the accompaniment of a song was played, while a gentleman at the company's exchange about a mile off sang the song. Each of the performers had a telephone held to his ear, so the musical

Digitized by Google

circle was complete, while the audience heard the song through the telephone with one ear, and the accompaniment in the room with the other.

Promotion of Scientific Knowledge. — Many of our readers will be aware that the King of the Belgians founded some time ago an annual prize of 25,000fr. (£1,000) for the promotion of scientific knowledge. This sum, which represents the third international prize competition, will be granted in the year 1889 for the best work on the progress of electricity as a motive power and for the purposes of illumination, on the various forms in which electricity is used or might be made use of, and on the economical advantages which the application of electricity appears destined to afford. Foreigners who desire to participate in this competition must send their essay printed or in manuscript before January 1, 1889, to the Minister for Agriculture, Industry, and Public Works in Brussels. A new edition of an already printed work will only be admitted to the competition when the same has undergone considerable modifications and been greatly enlarged, and provided the same shall have been issued, like the other works submitted, within the years 1885, 1886, 1887, or 1888. The essays may be written in any one of the following languages:—German, French, Flemish, English, Italian, and Spanish. The King of the Belgians will elect a jury as judges for awarding the prizes, composed of seven members—viz., three Belgians and four foreigners.

The Electrolytic Cartridge.—We learn from a description of these cartridges given by a contemporary that the cartridge consists essentially of a glass tube of a diameter to fit easily into the borehole, which should be small. The tube is very strong, the thickness of its walls being about equal to the diameter of the bore. Two wires are fused into this tube, which is hermetically closed after being nearly filled with water rendered conductive with a little acid or some metallic salt. When this cartridge has been inserted into the borehole, and the latter tamped or stemmed in the usual way, its projecting wires are connected with cables serving as "leads" from a source of electricity. All being ready, the current is put on, and the current from the generator passes between the ends of the wires within the glass tube and decomposes the water. The explosive mixture continues to accumulate as the decomposing action of the current goes on. It is to withstand the increasing pressure of the liberated cases that the thick glass is required. So long as the ends of the wires are covered by the liquid, no spark can be produced to ignite the gaseous mixture; but when these—or one of them—are laid bare by the conversion of the water into gas, the current has to pass through the latter, which is then fired. The resulting explosion is extremely violent—more violent than that of nitroglycerine even.

The Lighting of the City.—In his annual report to the Commissioners of Sewers Colonel Haywood says:—Upon the whole it appears desirable for the Commission to offer very liberal terms indeed to those willing to embark in the enterprise of supplying a fairly-sized district of the City with electricity rather than to undertake the work themselves. The risk of profit to the enterprise would be considerable, even if the promoters be paid most liberally for the supply they give; but whatever the cost may be, it would be a cheaper and a better way of obtaining a supply of electricity, either for the city of London or any part of the metropolis, rather than for local authorities to undertake it in the present condition of electrical science. Unfortunately, at the present time there is a complete stagnation in electrical enterprise upon a sufficiently large scale for the supply to a town or large district. This I believe to be solely attributable to the operation of the Electric Lighting Act, under which those embarking in such undertakings are fettered in many ways, and may, after a large expenditure and years of trouble, be deprived of the fruits of their labour with most inadequate compensation, just when success might begin to reward them. Nothing short of the repeal of that Act, or a fundamental alteration in most of its provisions, will bring capital into electrical undertakings again; and the Commission would, I believe, most usefully use its power and position in obtaining an alteration or repeal of the Act.

The Telegraph and the late Riots.—The report of the Committee of Inquiry into the matter of the late West End riots contains the following:—"We have also to call attention to the very inadequate arrangements made for telegraphic communication between the police in the streets and the Commissioner's head-quarters at Scotland-yard. We find that no constable was aware that from the War Office it was possible to have sent a telephonic message to Scotland-yard at any time. Had the police-constable, who is always on duty in front of the War Office, been aware that he could send such a message, he could easily, when the mob had assembled in front of the Carlton Club, have informed Scotland-yard of the fact, where arrangements could have been made for heading the mob. The same want of system is evident with regard to the use of the postal telegraph. The constables on duty at the bottom of St. James's-street, where there is a postal telegraph office, should, in our opinion, have had the power of entering the office and giving the order to the telegraphist on duty to clear the line at once to Scotland-yard. Had this been done, a message could also have been received by the Commissioners there, which would have enabled them to have taken prompt measures. The same applies to all other telegraph offices along the route taken by the mob. We also wish to call attention to the fact, that at Scotland-yard, and the police stations generally, there seems to be no telegraphic signal by which the urgency of any particular message can be specially indicated."

The Electric Light for War Ships.—A trial has just been made at Portsmouth of an installation of the electric light, which has been fitted on board the "Impérieuse" by Messrs. Siemens Brothers and Company, who are also about to provide similar installations on board the "Warspite," "Edinburgh," "Collingwood," and "Rodney." The lights on board the "Impérieuse" comprise 375 incandescent lamps of 20 candle-power, which are disposed so as to illuminate all parts of the ship, including the engine rooms, stokeholes, and magazines; and also a couple of search arc lights, placed at the bows and at the stern, and which are each equal to the power of 25,000 candles. The currents are generated by three Siemens dynamos, on the combined and self-regulating principle, each of which is driven by one of Willans's compound two cylinder engines, which is fixed to the same bed-plate as the machine which it drives. The number of revolutions per minute is 400. The machines are interchangeable, and can be connected or thrown out of action by a simple switch arrangement. One of the machines supplies the search lights, and another is equal to maintaining 320 of the incandescent lamps aglow, which is considered as many as will be necessary as a rule to be alight at the same time. When the whole of the incandescent lamps are required to be lighted at the same time two dynamos will be demanded for the several leads, otherwise one will be kept as a reserve against accidents. The arrangements have been superintended on behalf of the company by Mr. Collings, and the preliminary trial during the day and after dark proved very satisfactory.

TELPHERAGE.*

BY PROFESSOR JOHN PERRY, F.R.S.

(Continued from page 289.)

It has been suggested by our friend, Mr. Gordon Wigan, that instead of the wire we might have a copper strip attached all along the train to the more or less flexible draw bars, and that the draw bars might be brought much nearer to the rod than they are in this model, and that the contact of such a strip of copper with fixed brushes, or pulleys, might easily be arranged for.

In our system there is no necessity for insulating any part of the steel rod on which the trains run; but you will see presently that such insulation has given no trouble whatever; whereas the hanging wire might by its oscillation become entangled in some part of the train, while in the copper strip and drawbar, or *back-bone* plan as we call it, which Mr. Wigan has suggested, an expensive brush or pulley must be placed at every post. Although, therefore, both the plan suggested by Mr. Wigan and our own plan which you see carried out in this model, obviate the disadvantage of the reversal of the current when the train is passing the posts, neither of them is as simple as that of Prof. Jenkin.

Here is another model, worked on the Cross-Over System, in which the ends of the Telpher Line are stiff and the inter-

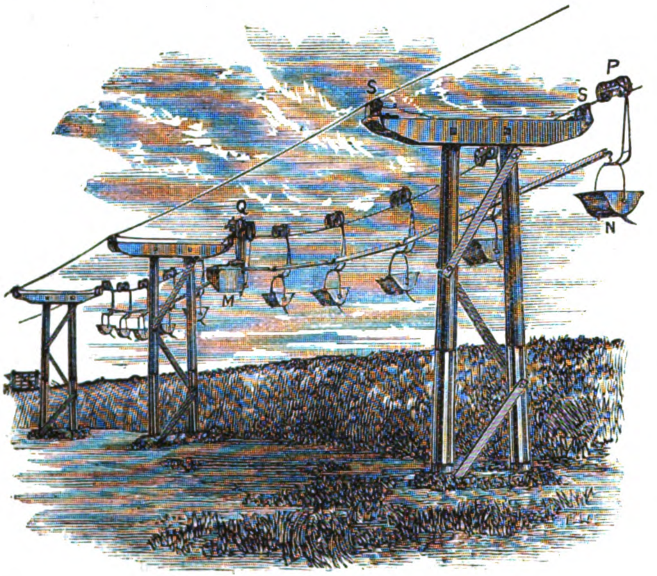

Fig. 9.

mediate parts flexible. Imagine these rods as being each 66ft. long and about 18ft. above the ground, supported on rough timber posts, here going across a river, there over houses, rising and falling and curving about as the ground and obstructions require it to do; imagine also these flexible rods as being 8ft. apart everywhere, and their aggregate length a number of miles, then with these buckets weighing nearly 400lb. each, you have a real telpher line. [Model of Cross-Over Parallel Telpher Line shown working.]

To assist your imagination I will now throw on the screen views taken from three photographs of the Glynde line. The first (Fig. 9) gives a view of the train just before it crosses the river, and you see the river embankment behind the posts. Observe the rough construction of the posts, the straightness of the steel rods before and behind the train, and their sag or dip underneath the train. M is the locomotive which pushes five skeps and pulls five others. It was up this steep incline that we started running on our opening day, when so many engineering authorities were present, and it is this part of the line which is shown crowded with spectators in the engraving of the *Graphic* newspaper.

In this second view (Fig. 10) we see the river itself, there being a descent on both sides of the portion now in view. The line rises here to give the headway necessary over a small navigable river, and the temporary bridge erected by us crosses the river in front of the engine house A.

In the third view (Fig. 11) the nearest post is the one in front of the engine house, and we look towards the clay field from which the skeps are coming loaded.

In this fourth view (Fig. 12) we have the stiff curve at the railway, where the skeps discharge their load of clay into the

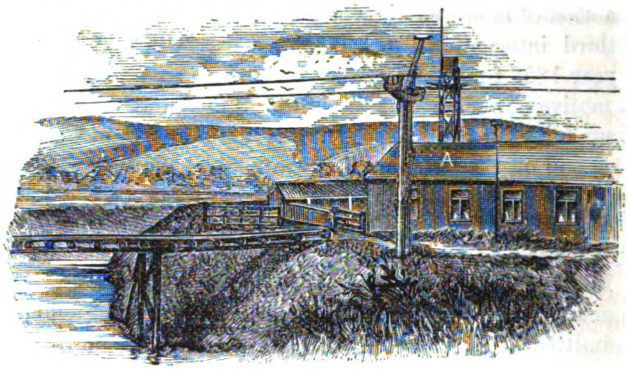

Fig. 10.

railway waggon (see Fig. 17). Some of the supports here are different from the others, being older ones used in some of our earlier experiments. The motion of the train over this curve has a beautiful appearance from the railway bridge.

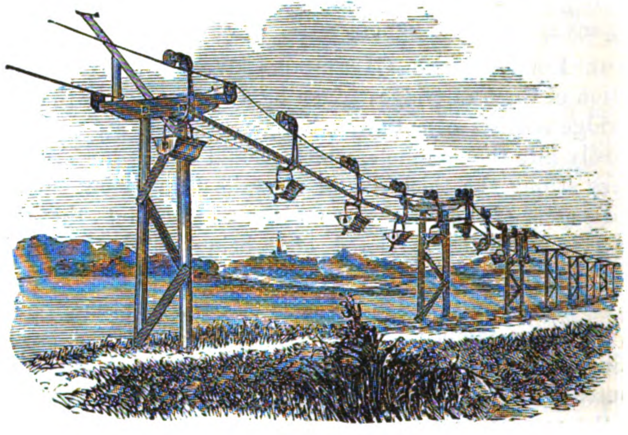

Fig. 11.

In this map (Fig. 13) A is the clay field, where there is a stiff end; B is at the railway siding; C, C shows the flexible part of the line, there being only one stiff part at the curve D; E is the engine house.

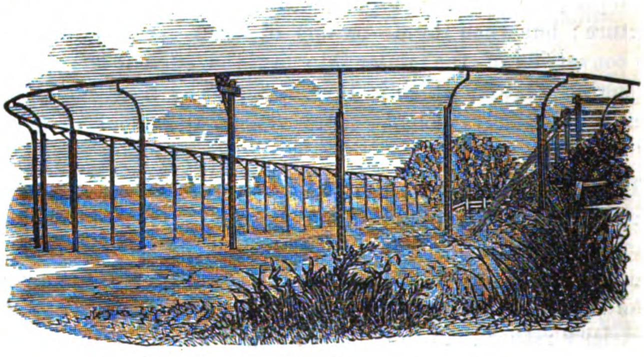

Fig. 12.

Returning to the model. When I send a current you see these two trains proceeding steadily round and round, each of them propelled by its little locomotive placed in the centre of each train. Observe that we have a block system. One of the trains moves more slowly than the other, which is continually trying to run into the first, and is always being pulled up when it comes within too short a distance of the front one. [Absolute Block shown in action.]

* Lecture delivered at the London Institution, 28th January.

In the construction of an ordinary railway one of the greatest expenses consists in obtaining permission from Parliament to buy land compulsorily; another is the price of the land itself; further, the railway when it does not follow, and it very seldom does, the surface of the ground, must have great embankments made for it, and deep cuttings and tunnels, not to mention that the cost of a railway bridge over a river or a ravine would sometimes swallow up all the possible profits on a short line of ordinary railway. Now, for a Telpher Line the land need not be bought, only way-leave being required; neither embankments nor cuttings are necessary, the uses to which the fields have been put need not be changed, and the crossing of a river or ravine is as easy and inexpensive as carrying the line over ordinary ground.

I remember once lying on the heather, resting in a certain dale in Derbyshire. It was soon after the Telpherage Company was started, and I saw a very long heavy goods train coming out from a tunnel in the mountain on one side of the dale, moving slowly over a railway embankment, which was about a mile long, and passing into the mountain on the other side of the dale.

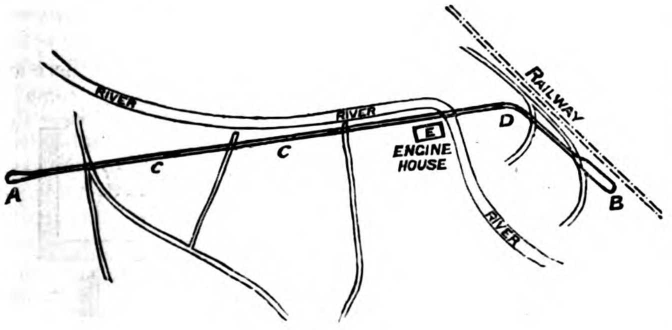

Fig. 13.

When I considered that each of the waggons moving before me might contain 15 to 25 tons of material, and the great number of waggons in a train, and contrasted it with what I knew that a single telpher train was likely to be able to carry, I was for some time very sad in thinking on the prospects of telpherage. But after I had rested there a whole hour, and found that that one goods train was not followed by any others, that for the conveyance of about one train in two hours that costly railway had been built, which was fitted to carry 100 times as much, I felt that perhaps a very cheap line, every part of which was constantly in use by a continuous stream of material passing over it, might really have been very much more economical than the railway I was looking at.

When we consider that electricity furnishes the means of conveying to this little locomotive from a great distance the power required to drive it, that it needs no coals and carries no water, that it need not be much heavier than any one of the ten carriages which it propels, and when we also consider that although each of the numerous trains running on such a line receives its power from the same source, which may be a dynamo machine driven by a steam engine, or driven by a water-wheel or a water-fall, which is several miles away from any part of the line, yet these trains do not interfere with one another excepting when there is danger of a collision, and the interference is then of a very decided character, it will be seen that the idea was one which was certain to be regarded when fully developed as likely to be of tremendous importance in the history of civilisation. As the idea gradually developed we saw that telpherage had no chance of competing with ordinary railways; but we also saw that it was not possible by any ordinary railway system to compete with horses and carts, when the quantity of stuff to be carried was comparatively small, because twenty little steam locomotives, each of one horse-power, would be decidedly uneconomical, even if they could be worked without separate drivers, whereas with telpherage it was quite feasible to have a single train representing the load drawn by a strong horse, and each of our little locomotives might be driven with a wonderful amount of economy. It was known to us, as to other electrical engineers, exactly what was the waste in conveying electric power, and it was seen that our rod might be very light, and therefore cheap, and the whole permanent way cheap if the loads could be subdivided into units of from 2 to 3 cwts. each, so that a weight of 30 cwts. could be spread over a considerable length of line. We saw also that it was possible to develop the system in another direction, and by using stiff girders to carry heavier loads as quickly as we pleased.

When the experiments at Weston and elsewhere were concluded, we proceeded to erect a Telpher Line to take clay a distance of nearly one mile to the Glynde Railway Station, for the Sussex Portland Cement Company (Limited). The designs were made under Prof. Jenkin's superintendence by the staff of the company, but unfortunately in June last the inventor of the Cross-Over System died; and I, whose only claim to credit in this system of Telpherage may be said to consist in having been made by Prof. Jenkin one of his two partners in the enterprise, had the great advantage of being asked by the directors of the company to succeed him as the engineer of the line. Although I had at once to take charge of such design work as had still to be completed by the staff of the company, it was not until the end of July that I was able to settle down at Glynde to superintend the erection of the line. I have been very ably assisted by Mr. Brewtnall, Mr. Crackanthorp, and Mr. Anderson; but the erection of a first working line of such a character as this tried to the utmost my patience and ingenuity. I did certainly introduce modifications into the scheme, but my great desire was to follow as closely as possible the plans of Prof. Jenkin, and although I must confess that I should have preferred to see the development of an Ayrton and Perry system of telpherage, I was all the more intent to construct the Glynde line exactly as I thought the designer himself would have constructed it. I had sometimes difficulty to find the point of view from which he would have looked at some of the problems before me; but I think that his plans were as little changed as they would have been had he lived to carry them out.

If you look at this model and at this map (Fig. 13) you will have no difficulty in understanding how the Glynde line is worked. The steel rod, $\frac{3}{4}$in. in diameter and 66ft. long, has its ends turned sound, and fastened with nuts to these cast-iron saddles (S, Fig. 9) and shown in detail in Fig. 14. Every

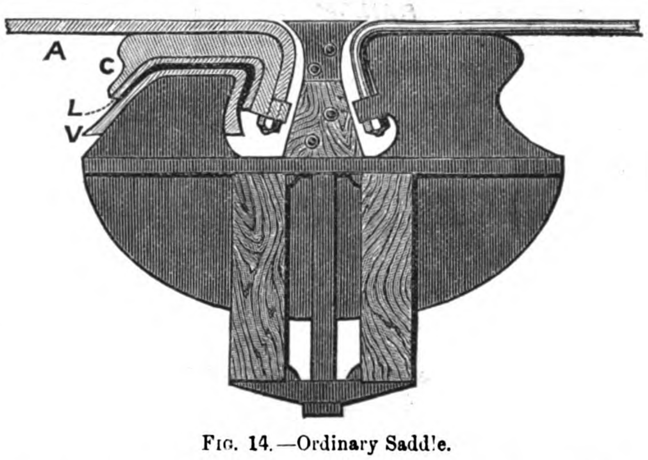

Fig. 14.—Ordinary Saddle.

alternate rod is insulated, and the rod A passes not over the cast-iron saddle itself, but over a cast-steel cap C, which is insulated from the saddle S by an insulator of vulcanite V, and in order that the tension in the rods may be very considerable without fear of the vulcanite cracking or getting broken, melted lead is run in between the vulcanite and the steel and between the cast-iron and the vulcanite, so that the force acting on the vulcanite acts over a wide area of soft lead L. The lead, which was, I believe, suggested by Mr. Charles Wood as preferable to Portland cement, has worked admirably; and since the line was erected we have not yet found that there has been any breakdown in insulation anywhere. The shape of the buckets used you

Digitized by Google

will gather partly from the model and partly from the diagram of the real bucket, a side view of which is shown in Fig. 15, and an end view in Fig. 16. At the railway siding the buckets pass over the middle of the railway waggons, as shown in Fig. 17, and the buckets are, one by one, *automatically* tipped and their load of clay discharged into the railway

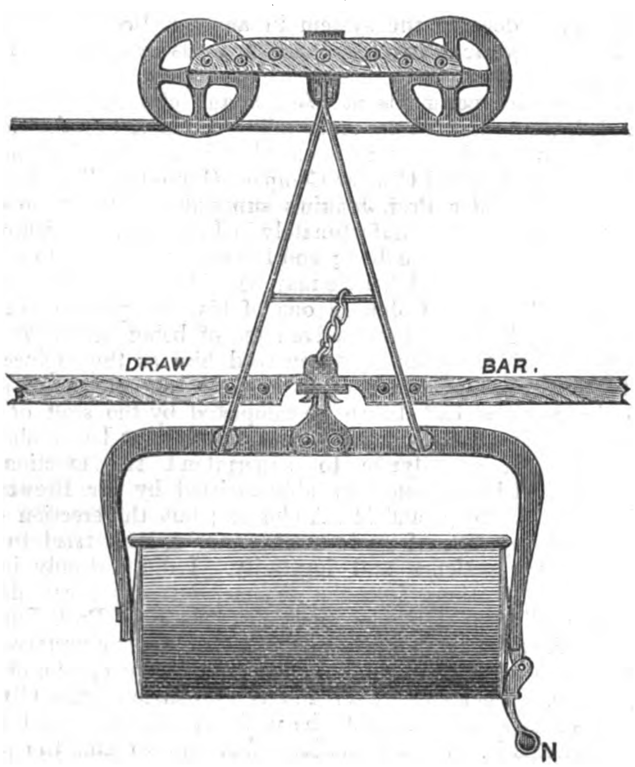

Fig. 15.—Ordinary Bucket (side view).

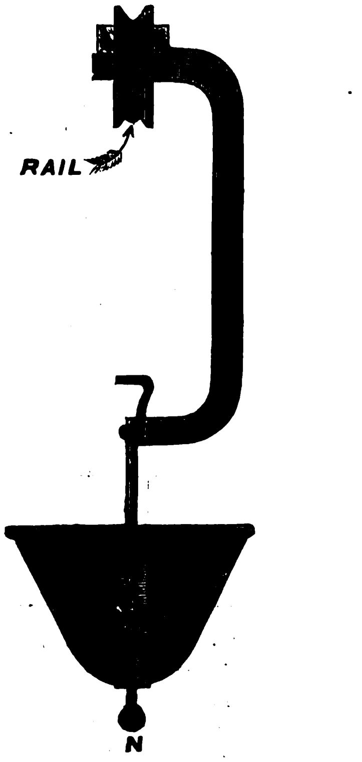

Fig. 16.—Ordinary Bucket (end view).

waggon by the handle N (Figs. 9, 15, and 16), attached to each bucket striking against a buffer, which is made to project from a post at the railway waggon into which the clay is to be emptied.

The old form of skeps experimented with at Weston was copied from those which are used in wire-rope tramways; but it was found that when the pull on the draw bar was suddenly altered these old skeps had a tendency to rear up, and there was a danger of their falling off the line. In the drawing before you of the skep and attachment (Fig. 15), used at Glynde, you will notice that the draw bars are so placed as to produce no tendency to rear when the skeps are suddenly started or stopped, and I believe that in no single instance during three or four months' work has such an accident occurred. You will see that we can hang any load from the hanger, such as a bag, or parcels, or logs of wood by bands instead of the bucket, and in the model we have illustrated this by re-

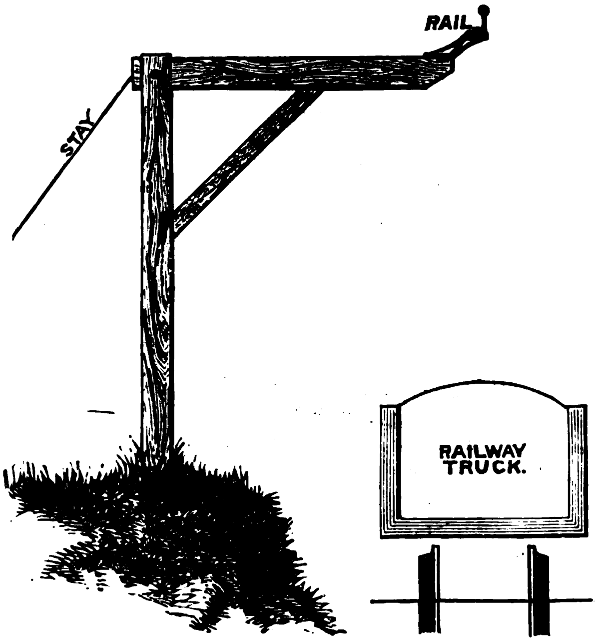

Fig 17.

placing some of the buckets with miniature logs of wood, sacks of shot, &c.

(To be continued.)

LITERATURE.

Dynamo-Electric Machinery. By Prof. Silvanus P. Thompson. [E. and F. N. Spon.]

This is a second and enlarged edition of the book published by the author in the autumn of 1884. Since that time the science and practice of dynamo-electric machinery has advanced with rapid strides, and to keep pace with this development Prof. Thompson has considerably increased the volume of his book, adding over 100 pages letterpress, and nearly the same number of illustrations to the original edition. The general arrangement of the work has, however, not been altered, and as we have already reviewed these in a former number, we shall confine our remarks to that which is new in the present edition.

In Chapter VII., which deals with the types of machines having closed coil armatures, descriptions have been added of the new Gramme armature for large current, of the vertical pattern (1881) Gramme dynamo with salient poles as distinguished from the original horizontal type with consequent poles, of a portable 4-pole Gramme dynamo (type of 1885), of the Breguet type of Gramme machine which, in external appearance, closely resembles Crompton's latest design of Gramme's vertical heavy current machine (type of 1884), of Hochhausen's dynamo, of Kapp's slow-speed dynamo, of the Phœnix dynamo, of M'Tighe's dynamo, of the "Manchester" dynamo, and of the new Siemens vertical dynamo (type of 1885), which also resembles Crompton's design very closely. When criticising the latter the author expresses astonishment that the pole pieces are made considerably thinner than the cores of the magnet, a feature which is in direct opposition to his recommendation on p. 110, where he says:—"If pole pieces are

Digitized by Google

used they should be massive and of the softest iron, for reasons similar to those urged above." Now a general rule like that here quoted is apt to be misleading. In some machines, as for instance in the "Manchester" dynamo, massive pole pieces are an unavoidable feature of the general design, and, as such, a necessity; but in some other types no excess of mass is required, and, if applied, may do more harm than good by facilitating an external leak of lines of force. The functions of a pole piece are two—first, to conduct the lines from the magnet core, where they originate, to the surface of the armature, where they do their work; secondly, to reduce the magnetic resistance of the air-space, which object is attained by expanding the pole piece as far as is possible without producing a serious leak of lines. The cross-sectional area of the pole piece at any point is therefore governed by the number of lines which pass at that point, and it is evident that if the field magnets are of the double horseshoe pattern, as in the Siemens or Crompton machines, the centre of the pole piece has not to carry any lines, and might therefore be made as thin as is compatible with mechanical strength. In single horseshoe magnets the area of the pole piece at the centre—that is on a line at right angles to the diameter of commutation—need only be half the area of the magnet core, because half the total number of lines only have to pass that point. In Chapter VIII. dynamos with open coil armatures are described at great length, and the new "Brush" armature core has been added to the original excellent description of the "Brush" dynamo. The Thomson-Houston dynamo is also very fully treated, and the changes of current through the three armature coils during one revolution are very clearly explained. It would, however, have been well if the author had gone a little beyond a mere description, and had shown what part self-induction plays in this machine, especially during the time the brushes are shifted for the purpose of regulating the current. The student would certainly desire to know how it is that an armature producing an electromotive force of several thousand volts is not burned up by a process of regulation which necessitates a periodic short-circuiting of the coils when in a strong part of the field. Chapter XI. is entirely new, and a very welcome addition. It treats of dynamos for electro-plating and electro-metallurgy. As yet there are only very few manufacturers who make machines specially for that purpose, and general information of the requirements of this class of work is obtainable only with great difficulty. The reader will find in Prof. Thompson's book most of the data which are necessary to guide him in the choice or in the design of a dynamo for electro-deposition. Those relating to copper are so generally useful that we make no apology for reproducing them here:—

Current	1	ampere	deposits	·000326	grams	per second
„	1	„	„	·01957	„	per minute
„	1	„	„	1·1739	„	per hour
„	851·8	„	„	1	kilogram	per hour
„	386·4	„	„	1	lb.	per hour

A new chapter (XIX.) has also been added on the coupling of two or more dynamos in one circuit. The author justly ascribes to M. Gramme the merit of having pointed out how two series dynamos may be coupled in parallel, but when speaking of the coupling of several compound machines the reader receives the impression that this was first done by Mr. W. M. Mordey, and is, in fact, a new discovery. Such an impression would certainly be erroneous, for in an installation erected by Messrs. Crompton and Co., at Berechurch Hall, in 1882, four compound machines were coupled precisely in the manner described by the author. As regards the coupling of alternate current dynamos, the reader will find in Chapter XIX. a most interesting and clear description of the various phenomena which present themselves, and of the experiments carried out at various times by Wilde, Hopkinson, and Adams. The chapters treating of the "Dynamo as a Motor," of "Theory of Motors," and of "Electric Transmission of Energy" remain as they were. We trust that in a future edition they may receive the same attention as those on dynamos. As they stand they are of little practical use, as too much stress is laid on the question of electrical efficiency quite irrespective of the commercial efficiency. It would also be well to finally abandon the figure 746 as representing the number of watts corresponding to one horse-power. We know from Lord Rayleigh's determination of the ohm and volt that the exact figure, neglecting fractions, should be 736, and think it high time that the correction should be made in all new books. Speaking of the government of motors when supplied with a constant current the author states that a constant speed at variable loads can be obtained by any of the following three combinations:—

(*a*) Magneto motor with shunt regulating coils.
(*b*) Series motor with shunt regulating coils.
(*c*) Series motor with long shunt regulating coils.

All these are based upon the critical condition, as regards speed and external resistance, if the motor be used as a dynamo. In basing his theory on the critical condition the author has evidently overlooked the fact that, although a dynamo has a critical speed at which it will begin to magnetise and produce a current, a motor has no critical speed, because its field is produced by a current from an external source, and that all theories based upon the assumption that a motor will develop counter electromotive force only after the critical speed has been exceeded must lead to wrong results. It is questionable whether the problem of governing motors which are supplied with a constant current can be solved at all by compound winding; in all probability it will be found that something more is required in the shape of some external regulating apparatus. Whatever be the scientific aspect of the question, the broad fact remains that, whereas motors have been made which regulate fairly well when supplied with a constant E.M.F., nobody has, as far as we know, yet succeeded in constructing a self-regulating motor when the condition of supply is a constant current. We hope in a future edition Prof. Thompson will treat the question more exhaustively.

The appendices have been considerably increased in number and also in interest. The latest theories of other writers on dynamo machines are given, as well as some experimental evidence and data from actual practice. An excellent description of the different electric governors in use will also be found here. Appendix XI. contains some statistics of recent dynamos, and is therefore of great practical value. We feel indebted to the author for having given this information, but we sincerely wish it were fuller. It is probably not his fault that the list is very short; makers are, as a rule, very unwilling to let authors have full information, and Prof. Thompson has done the best he could with the material accessible to him.

The book, as a whole, will be found extremely useful to the practical student. It has all the merits of the former edition, and in addition the merit of being brought as nearly up to date, as regards dynamos, as the rapid progress in this branch of applied science will permit. If we have ventured to criticise some parts of it, and especially the part concerning motors, it is because we wish to see in a future edition the whole problem of motors treated more exhaustively, and because we feel convinced that the author would, if he chose, be fully equal to the task.

ELECTRIC HEADLIGHTS.—Recent experience in Russia appears to show, says *Nature*, that financial considerations are not alone unfavourable to the system of electric headlights for railway engines. On the railway between St. Petersburg and Moscow several locomotives were fitted with electric lamps. For a time they gave great satisfaction, lighting the way more than a kilometre in front. But the *employés* began to complain of the contrast between the lighted and the unlighted surfaces painfully affecting the eyes; and doctors ere long reported that there had been several cases of grave injury to the eyes in this way. Hence the lamps were abandoned. The directors have not, however, given up the idea of better illumination of the line; and they now contemplate placing the electric lamps so as to illuminate about a kilometre on either side of the station.

TWO ELECTRIC LIGHTING COMPANIES.

Of the electric lighting undertakings which have survived the storms and wreckage of the past four years, two important ones, the ANGLO-AMERICAN BRUSH CORPORATION and the MAXIM-WESTON COMPANY, have recently held meetings, at which information was given not wholly unsatisfactory. There remain besides, several companies and private firms engaged in the business as prosperously as ever; and some other corporate concerns which have started more recently on different lines, profiting by the experience of their predecessors, seem to have an encouraging future before them. But of the countless host which entered the field of operations in the heyday of its promise, scarcely any have retained their identity or escaped annihilation except the companies referred to. But when we have said this we have said the worst; for the very fact that they retain any vitality at all under the extremely adverse circumstances they had to contend against is proof not merely of the merits of the system they have severally been promoting—which is a matter affecting chiefly the pockets of their shareholders—but also that the business of electric lighting is not wholly discredited, which is a matter that more generally concerns the British public. We all know perfectly well what have been the causes of the many failures, so complete and disastrous; that some few adventures have escaped the general fate is a thing almost to be wondered at, and is on that account all the more a subject for hearty congratulation.

The step which the MAXIM-WESTON COMPANY have now taken by again striking off their unrepresented capital in order to enable them to pay a dividend is one for the shareholders alone. At first sight the process looks like throwing the biscuits overboard to lighten the boat; but if in reality what once represented stored provisions prove to be nothing but empty tubs, the sooner they are cast adrift the better. It is represented that a satisfactory dividend has been earned during the year on legitimate business worked by the existing capital, and to this the shareholders have preferred a claim. Both in their immediate interests and for their future chances of enhancing the market value of what remains of the original investment the reduction of the nominal capital to its actual dimensions, though a questionable operation at best, is the course that seems wisest in their eyes. With a valuable system such as the MAXIM-WESTON COMPANY undoubtedly possess, their operations ought now to be remunerative; and if, as is alleged, considerable profits have been made in recent months notwithstanding the amount of plant thrown on the market by companies in liquidation, the shareholders may confidently look with renewed hope to the results of fresh contracts for the current year.

With the BRUSH ELECTRIC LIGHTING CORPORATION affairs seem to be even more reassuring. The business meeting of this company on the 10th inst. revealed that besides some absorption of minor undertakings, obviously to the advantage of all parties, the remunerative work carried out during the past year was considerably over that of the preceding year; while work which at first had been undertaken and kept on at a loss is now beginning to yield a profit. The Annual Report was itself highly gratifying, and the Chairman's speech at the meeting still more so. He is in complete possession of the facts on which his estimate is based; and his confidence in the future prospects of the undertaking over which he presides was apparently shared by those who listened to him. Some changes have been made in the *personnel* of the management which betoken no falling off in energy and vigilance. Exception might very well be taken to the line of business taken up conspicuously by this corporation for purposes of advertisement rather than gain in its earlier career; but it must be confessed that those who were responsible for it may now retort that it has paid in the long-run. The BRUSH COMPANY is foremost at all the great exhibitions—though it has not secured the Folkestone installation as it reckoned upon—and is the chief competitor for street lighting almost everywhere. It has virtually secured the lighting of the City of London on an extended scale, and at prices which, while not so high as to discourage invitations from other localities, are sufficiently so to enable the company to earn a profit. With its foreign business relations we are not so much interested, though they are extremely gratifying to the shareholders; but it is satisfactory to note that an English company is going to take to Berlin an article of consumption more genuine and less dangerous than the cutlery and bayonets which have lately been shipped to us from that quarter. If for no other reason we wish for this that the Brush Electric Light may inflict on the German capital an honourable revenge for British wrongs.

Both the companies we have referred to are counting upon a speedy repeal of the obnoxious clauses in the Electric Lighting Act. But for that malignant piece of legislation electric lighting industry would by this time have been in a position

Digitized by Google

far more promising and probably even flourishing. It is said that the late Government were willing to extend the confiscation clause from twenty-one to forty years. We are glad that the Directors of these Companies are holding out for an entire abolition of this provision. It is vicious in principle, and ought to be fought out on commercial grounds, if on no other. We cannot expect for electric lighting privileges which are granted to no other industrial undertakings; but we have a right to ask for the same privileges, and to protest against new political doctrines of questionable soundness and unquestionable immorality being applied to us because we happen to be the latest comers on whom an experiment can be tried. LORD SALISBURY'S declarations on this point were statesmanlike and fair all round; whether we sit on his side in politics or not it is surely a matter of the deepest interest to capitalists of all parties that the doctrine of ransom shall not be applied to industrial enterprise generally, as it certainly will be if the prospective seizure of electric lighting property should prove successful. We are glad to learn that this question is to be brought by LORD RAYLEIGH before the House of Lords, where it will have a chance of being honestly dealt with; and by the Chairman of the MAXIM-WESTON COMPANY in the House of Commons. If the objectionable clauses of the Act, one relating to the form of lamp, and the other to the confiscation of property, but especially the latter, could be got rid of, we should have no fears for the future of electric lighting; and the present financial condition of the two companies whose affairs we have been discussing goes a great way to support us in this confidence.

STREET RIOTS AND THE TELEGRAPHS.

On that part of Mr. Childers' Committee's Report relating to the employment of the telegraph in cases of public disturbances we venture to remark that London has never yet been in a state of siege like that pre-supposed by a scheme of the kind suggested. It was hardly to be expected that a civil force would take precautions such as could enter the minds of none but military men, and for an occasion when nothing worse was anticipated than a scrimmage between two hostile meetings where there was plenty of room to fight it out. The fact is, the diversion westwards of the worst elements in the crowd was a surprise to everybody, including probably the instigators who are now on their trial at Bow-street. If riots of similar seriousness are as infrequent in the future as they have been in the past, any arrangement for utilising the telegraph or telephone in cases of emergency would soon become a dead letter and altogether illusory. A signal for "clearing the line to Scotland-yard" is all very well from Lord Wolseley's point of view; but in reality it would drop out of memory through never being used. Of course, if we are to expect a regular recurrence of these disorders it may be as well to organise a street telegraph to Police Depots, just as we have done to the Fire Brigades. Short of this we do not see the utility of conferring powers which would be inoperative unless, as in the case of fires, frequently exercised. The Committee also make a great blunder in supposing that telegraphs designed for ordinary traffic and for long distances can be instantaneously used with advantage for short distances, such as those mentioned in the Report. There should be no delusion on this point. A mounted policeman will beat the telegraph easily for any distance under four miles. It was the absence of mounted patrols that led to all the mischief, and their presence at future demonstrations will adequately prevent any rioting without the help of the telegraph.

CORRESPONDENCE.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am obliged by your publishing my letter of the 15th inst., and also for your note appended to it. It is now manifestly the duty of "Hamlet" in the interest of science to give in your columns the following information :—

First. What kind of electrical apparatus was used?

Second. How was the electricity conveyed to the boy's body?

Third. What is the name and address of the man, seeing "Hamlet" says "he knew the man."

By "Hamlet's" giving the above information he will open a door for faith in his story.—Yours, &c.

JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, February 20, 1886.

P S.—I forgot to state that there were two electric boys publicly exhibited in this city; one of them was admittedly electrified by external means, the other, I maintain, was not electrified by external means.

TELEPHONIC RECEIVERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you or any of your correspondents kindly acquaint me through the medium of *The Electrician* with the nature of the composition used in the formation of the cylinder in the Edison receiver. I believe there is a type which does not require the application of moisture; of this, I would specially feel obliged for some information.—Yours, &c.,

Feb. 20, 1886. J. S. H.

DIRECT AND COUNTER ELECTROMOTIVE FORCES REPRESENTED BY AN HYPERBOLA.*

BY H. S. CARHART.

In the usual discussions respecting the relations between the electromotive force (E.M.F.) of the generator, the counter E.M.F. resulting from the electromagnetic reactions taking place in the motor, and the rate at which energy is absorbed by the latter in the electrical transmission of power, it is implicitly assumed that E is constant. Thus the equation, representing the division of the whole electrical energy spent in the circuit in unit time into heat and mechanical work, viz.:

$$C E = C^2 + W_{,}$$

is differentiated so as to obtain the first differential coefficient of $W_{,}$ with respect to C, R and E being constants. Hence $\frac{d W_{,}}{d C} = E - 2 C R = 0$ for a maximum, the second differential coefficient being negative. C is therefore equal to $\frac{E}{2 R}$, or the current is reduced to half the value it would have with the motor at rest, by the reduction of the effective E.M.F. to one half.

If, however, we take the equation expressing the electrical energy absorbed by the motor per second as the product of the counter E.M.F. and the current, we have, as is well known,

$$\frac{E_{,}(E - E_{,})}{R} = W_{,} \text{ or } E_{,}(E - E_{,}) = R W_{,} \quad . \quad . \quad . \quad (1)$$

From this it appears that if R and $W_{,}$ and constants, $E_{,}(E - E_{,})$ is also a constant. But when the product of two factors is a constant, their sum is a minimum when they are equal to each other. It follows that the sum of $E_{,}$ and $E - E_{,}$, or E, is a minimum, when $E_{,} = E - E_{,}$ or when $E_{,} = \frac{1}{2}E$. By substitution in equation (1) $E_{,} = \sqrt{R W_{,}}$.

* American *Journal of Science*, February, 1885.

Digitized by Google

With an assumed amount of work spent upon the motor per second and a given resistance R, E has a minimum value equal to twice $E_{\prime}$. This correspond's with Jacobi's law of maximum rate of working, or greatest electrical activity and constant E.M.F. Evidently the conditions of greatest activity and constant E.M.F. of the generator are identical with those of constant energy absorbed by the motor and minimum E.M.F. of the generator.

Equation (1) gives

$$E_{\prime}^2 - E E_{\prime} = - R W_{\prime} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

an equation of the second degree and therefore of a conic section. On applying the proper criterion it readily appears that the locus of this equation is an hyperbola. For the purpose of a graphical representation of the continuous relation between E and $E_{\prime}$, let us assume R $W_{\prime}$ equal to 225; minimum E will then equal 30 units.

Solving equation (2) for $E_{\prime}$ and substituting in the result successive different values of E as the independent variable, we obtain corresponding values of $E_{\prime}$ which satisfy the equation. Each assumed value of E gives two plus values of $E_{\prime}$. The hyperbola I is thus plotted, making the assumed values of E abscissæ and the corresponding ones of $E_{\prime}$ ordinates. $E_{\prime}$ is considered essentially positive.

By a comparison with the most general equation of a conic section, the constants of this particular one may be determined.

Thus, independently of the assumed value of R$W_{\prime}$, $e^2 = 4 \pm \sqrt{8}$ and $e = 1{\cdot}0824$, the other value of e making n imaginary. Also, $\cos a = \pm \frac{1}{e}$ and $a = 22° \; 30'$, the minus value of the cosine not being admissible because then m would become negative. But all values of E are positive, and hence m cannot be negative.

Since the cosine of the angle between the transverse axis of an hyperbola and its asymptotes is the reciprocal of e, it follows that the asymptotes of this curve are the axis of X and the diagonal O G, the angle between them being 45°. The character of the curve is thus entirely determined without knowing the value of R$W_{\prime}$.

Assuming now R$W_{\prime}$ equal to 225, the co-ordinates of the focus are $m = 32{\cdot}96$ and $n = 13{\cdot}65$.

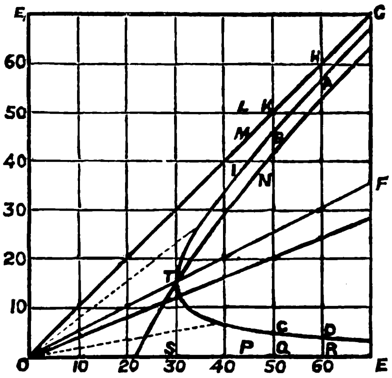
It is evident also from the properties of the hyperbola that m and n in this case equal A and B respectively. The perpendicular distance of the directrix from the origin is 30·45.

A number of inferences can be drawn directly from the curve by inspection. It is seen that E is a minimum when it is double $E_{\prime}$. At this point the hyperbola is tangent to an ordinate; the point of tangency will travel along the line O F, away from the origin or towards it according as the assumed value of R$W_{\prime}$ increases or diminishes. O F is therefore the line of minimum E, and its equation is $E_{\prime} = \frac{1}{2} E$.

The electrical efficiency at any point of the curve, being the quotient of $E_{\prime}$ by E, is the tangent of the angle which a line drawn from the point to the origin makes with the X-axis. The efficiency of T is the tangent of the angle T O E, or one-half. The electrical efficiency increases from zero, when $E_{\prime}$ is zero and E is infinite, to unity, when $E_{\prime}$ equals E and both are infinite; the angle, whose tangent is the measure of the efficiency, is then the angle between the asymptotes, or 45°, and the tangent of 45° is unity. The limits of the efficiency correspond to the points where the curve touches the asymptotes.

It is also evident that near the point where E is a minimnm $E_{\prime}$ increases most rapidly. That is, near the point where the efficiency is one half it has its greatest increments. Beyond an electrical efficiency of about 75 per cent. the direct and counter electromotive forces increase in nearly the same ratio, and the efficiency, therefore, increases very slowly.

The diagram shows further that $E_{\prime}$ and C pass through corresponding series of values, but in the inverse order. The current is proportional to $E - E_{\prime}$, the resistance being constant; and since the intercepts of a secant between an hyberbola and its asymptotes are equal, that is, A H equals D R for instance, when the counter E.M.F. passes through the series of values represented by the ordinates D R, C Q, T S, B Q, A R in succession, the current will be proportional to A R, B Q, T S, C Q, D R in succession. With the condition that the motor absorbs a constant amount of energy per second, the current is a maximum when the counter E.M.F. and the electrical efficiency are a minimum; and it diminishes continuously as the efficiency increases.



E and $E_{\prime}$ denote direct and counter electromotive forces; C current and R resistance in circuit connecting generator and motor; W the total electrical energy contributed by the generator, and $W_{\prime}$ the electrical energy absorbed by the motor in unit time; c the eccentricity; A and B the semi-axes; m and n the co-ordinates of the focus of the hyperbola; a the angle between the axis of X and the axis of the conic section.

If, now, the constant chosen is not the rate at which energy is absorbed by the motor, but the electrical energy contributed by the generator per second, we then have the equation

$$C E = \frac{E(E - E_{\prime})}{R} = W, \text{ or } E^2 - E E_{\prime} = W R \quad . \quad (3)$$

This is again an equation of the second degree, and its locus is the hyperbola I I. Its axis makes an angle of 157° 30′ with the axis of X, and its asymptotes are O G and the axis of Y. Its eccentricity is 2·613, the second value obtained from the equation $e^2 = 4 \pm \sqrt{8}$, the other value being the eccentricity of hyperbola I.

In this case the two machines and the conductor joining them form a system the only condition laid down being the constancy of R W. Hence the relation between E and $E_{\prime}$ may be found either when the motor is driven by the current and furnishes counter E.M.F., or when it is driven by mechanical means so as to contribute to the direct E.M.F. If the motor is actuated by the current, then E has its minimum value when $E_{\prime} = 0$, or at the point where the hyperbola crosses the axis of X; but if the motor dynamo contributes E.M.F. in the same direction as that of the other machine, then E may diminish still further, even to zero in the limit. In this case R W represents still the energy furnished by the generator, but not the total electrical activity per second. The part of the hyperbola lying below the axis of X corresponds to values of E and $E_{\prime}$ obtained when the motor is driven mechanically so as to furnish direct E.M.F.

In the first curve any assumed value of E greater than the minimum gives rise to two values of $E_{\prime}$, both positive. In the equation of the second curve the substitution of a positive value of $E_{\prime}$ gives two values of E, one positive and the other negative, indicating another branch to the curve. This other branch represents the relation between E and $E_{\prime}$ when the part played by each machine is reversed, the motor becoming the generator, and the generator becoming the motor by being driven electrically.

In curve two the efficiency is measured in the same way as before. Again it is seen to increase as the electromotive forces increase. The current, represented by the intercepts of the ordinates between the hyperbola and its asymptote O G, decreases as the efficiency increases. The same was true in the other case.

It remains only to point out that Jacobi's law of maximum rate of working applies only under the condition of a constant E.M.F. in the electric supply. This will be evident upon careful inspection of the diagram. The energy spent upon the motor per second is represented by $E_{\prime}(E - E_{\prime})$; the electrical energy supplied by the source per second by $E(E - E_{\prime})$.

Digitized by Google

The first expression is the product of the two parts into which the line denoting E is divided at any point by curve I. Since O G bisects the angle between the two rectangular axes, the ordinate of any point of this line equals the abscissa of the points of the hyperbola through which it passes. Thus K Q equals O Q or E, the direct E.M.F. corresponding to the points B and C of the curve. Hence B K equals $E - E_{,}$; and the product of B K and B Q, or the area of the rectangle B M P Q, is the constant R $W_{,}$ of the equation of this hyperbola. The area of all such rectangles is the same for this curve. In a similar way the area of K L P Q is the rate at which electrical energy is supplied to the circuit; and the difference between the two rectangles, or the square K L M B, is the heat waste per second at this point of the curve.

Now, while the area of the first class of rectangles is the same for all points of the curve, that of the second and of the squares diminishes as $E_{,}$ and the efficiency increase from point to point along the curve in the direction D, C, T, B, A. If the same analysis is applied to curve I I it will be found that the area of the rectangle expressing the electrical work spent upon the motor per second increases, the rectangles denoting the rate at which energy is supplied by the generator all equal R W, and the area of the square representing the waste in heat diminishes from point to point, as E, $E_{,}$ and the efficiency increase. We may therefore distinguish three cases, R being constant in each case :—

First, when E is constant.
Then $W_{,}$ is a maximum when $E_{,}$ is half E by Jacobi's law.
The electrical efficiency increases with $E_{,}$.
The current diminishes as $E_{,}$ increases.
W diminishes from a maximum to zero when the efficiency is unity.

Second, When $W_{,}$ is a constant.
Then E is a minimum when $E_{,}$ is half E.
The electrical efficiency increases with $E_{,}$.
The current diminishes as $E_{,}$ increases.
W diminishes from infinity to $W_{,}$ when the efficiency is unity. These are the limits.

Third, When W is a constant.
Then $W_{,}$ is a maximum only when the efficiency is unity, in which case E and $E_{,}$ are infinite.
E has a minimum value of $\sqrt{RW}$ when $E_{,}$ is zero.
(The case of the motor driven mechanically is not included.)
The electrical efficiency increases with $E_{,}$.
The current decreases as $E_{,}$ increases.

Jacobi's law applies only to the first case. When a battery is to be employed to run an electric motor, then E is the proper term to consider constant; but if it is required that the motor furnish a definite amount of power, then the graphical illustration of hyperbola, I, shows that E has a minimum value and points out some of the conditions of high efficiency.

DYNAMO TESTS.*

(Continued from page 254.)

It was intended to determine by experiment the specific heat of the specimens of the iron used in the calorimeter, but circumstances made this impossible. The value used,

·112,

is taken from determinations by Bystrom, Weinhold, Regnault, and Bede, reduced to 30deg. C. The values given by these different experimenters agree very well, and it seems probable that the mean does not differ from the specific heat of the iron used in the calorimeter by more than one or two per cent. at the most—an error that enters as about one-tenth in the result.

The weighings were made with a scale beam by Fairbanks. Both the weights and graduation had been tested. The results obtained are given in Table A following.

* From the *Journal* of the Franklin Institute.

TABLE A.

Correction for weighing in air	1·38
Water equivalent, corrected	1362·00

Temperature Observations.—The thermometers used were those by Green, already described. The time the mercury crossed each half degree was observed, and was taken as the mean of the times of crossing the tenths below and above the division, and the division itself. The times were noted by a chronometer.

The following table gives the temperature observations and the dynamometer readings—the latter were taken each minute:

Calorimeter Observations for Checking Dynamometer, June 27.

The corrections to be applied to the thermometer readings are for the part of the stem in the air, and for radiation. The first of these is somewhat indefinite, as a portion of the stem is heated by conduction from the calorimeter. The whole correction, however, is only about one-third per cent., and its value is probably correct within twenty or thirty per cent., so the error in the result from this cause can hardly be much over $\frac{1}{10}$th per cent.

But the most important correction, and the one in which there seems the greatest possibility of error, is the coefficient of radiation. This is usually determined by slowly stirring the calorimeter, and noting its difference of temperature from the air and rate of cooling, correcting for the heat developed in stirring. But with a single thin blade, and no arrangement for causing circulation, this method was impracticable. In some experiments that were tried, the water was not thoroughly mixed, and the cool water falling and warm water coming to the top, made the values obtained worthless.

Digitized by Google

Under these circumstances, it became necessary to calculate the radiation from the experiment for the determination of the mechanical equivalent.

The method of calculation was as follows:—The observations were divided into intervals of 4·5deg. C., as shown in the following table, and the corresponding intervals of time were reduced to the same rate of doing work, the same value of the specific heat of water, and the same value for the stem correction of the thermometer. The remaining difference in the intervals is assumed to be due to radiation.

Gives radiation ·00258° per degree per minute.

* These are the ratios of each succeeding interval to the first interval.

The differences of these corrected intervals from the first interval were plotted, the excess of the mean temperatures of the intervals over that of the air being taken as abscissæ, and the above differences as ordinates. A straight line was drawn through the points thus found. The radiation was calculated by taking the difference of the ordinates for an interval of 4°, and from this value (which is the loss of time due to radiation, in an interval of about 5·55 minutes, the difference of temperature being 4°) the coefficient of radiation was easily found.

In drawing a straight line through the points, we have assumed the coefficient of radiation to be constant when the excess of temperature over that of the air varies, instead of increasing with the excess. Within the rather narrow limits of temperature used, however, the value found represents very nearly the radiation for the mean interval. In calculating the experiment by the second method, the value of the radiation found above was corrected to the greater difference of temperature between the calorimeter and air, by increasing it in the ratio shown by the experiments of McFarlane and Rowland.

This method of calculating the radiation, while not so accurate as the method usually employed, has the advantage that the conditions of observation are accurately those of the experiment to which the radiation is applied.

It will be seen that the errors likely to affect the radiation coefficient are errors of observation, in the relative values of the specific heat of water at the different temperatures, and in the ratios of the stem corrections.

As for errors of observation, the dynamometer readings for the intervals were the mean of five observations, and, although the jar interfered somewhat with the readings of the thermometer, yet the table shows that there were no very great errors, and the method of observation allowed the readings to be to some extent corrected by those on either side.

The ratios of the values of the specific heat of water for the different intervals were calculated from Rowland's values of the mechanical equivalent for the mean temperatures of the intervals. Fortunately the correction was small, and probably accurately given.

Whatever the absolute value of the stem correction might have been, there could be little error in the relative values for the different intervals.

The result obtained was :—

Excess of cal. over air, 4° C.	coefficient of radiation, ·00258
8° C.	·00262

On applying the above values to the observation by the first method, we obtain :—

Mean rise of temperature, per minute (uncorrected)	·809814
Mean correction for radiation,	+ ·017790
Mean correction for stem,	+ ·003034
Mean correction to absolute temperature,	− ·001350
Mean rise, per minute (corrected)	·822288
Water equivalent of calorimeter,	1362 0 pounds.
Heat units developed, per minute,	1119·9562
Mean reading scale beam,	663·9
Friction reading scale beam,	13·72
Difference reading scale beam,	650·18
Mean revolutions,	720·1
Work in foot pounds = product × 3·3 × 1·0025	15489048
Mechanical equivalent for 1° C.,	1383·01 ft. lbs.
Mechanical equivalent for 1° F.,	768·34 ft. lbs.

Unfortunately, however, the construction of the calorimeter made the results of this experiment untrustworthy. The blades were kept apart by pieces of 4-in. pipe, ⅛ in. thick, fitting over the shaft between them. In the space between the shaft and pipe were about five pounds of water not in circulation with the mass in the calorimeter. The shaft being jacketed with this layer of water must have gained heat but slowly. The result was that the heat units calculated were too great, and the mechanical equivalent too small. It is also probable that this effect would make the coefficient of radiation calculated from this experiment slightly too large.

We can only say of this experiment, then, that the value is

768·3 + an indeterminate correction.

Second Method.—In this method water was made to flow continuously through the calorimeter. The engine was run

until the temperature of the exit water ceased to rise, and then observations of the entrance and exit temperatures and of the dynamometer were taken each minute, and the exit water weighed every four minutes. The weighings were made by two of Fairbanks' platform scales that had been tested with standard weights. The observations lasted one and one-half hours. The heat units were calculated for each interval of four minutes, as shown in the table, and their sum taken for the whole interval. The scale reading and number of revolutions of the dynamometer were averaged for the time of the experiment, the work being calculated from the means (Philadelphia time).

When the experiment was finished, the two cocks on the calorimeter were closed, and the engine stopped. The temperature of the water was then found to be 39°. The time occupied in stopping was about four minutes, equivalent to two minutes on full load. From the data of the previous experiment, the rise of temperature would be about ·85° C. per minute, and therefore the average temperature of the calorimeter during the second experiment was about 37·3°.

(To be continued.)

DUNDEE NATURALISTS' SOCIETY.

On Saturday last the members of this Society gave a *conversazione* in the University College, Dundee. During the course of the proceedings, Mr. Thomas Reid, who had charge of the engineering department in the absence of Prof. Ewing, gave a short address in the engineering lecture room on the storage of electrical energy. He pointed out the causes which necessitate some means of storage, explaining the conversion of energy which takes place in charging and discharging the batteries, the application to lighting, and the driving of tramcars, &c. In the department of mathematics and natural history a number of very interesting experiments were made during the course of the evening. These included the lifting of a 28lb. weight by a train of wheels connected with a small Griscom motor; the effect of the electric current on a large electro-magnet; the lighting of a small tank at the will of the visitor by electric lamps burning under water, and the apparently still appearance of a rapidly turning disc with coloured sections when viewed by the electric spark from a Wimshurst machine. Experiments in light and sound took place in some of the smaller rooms. In the electrical engineering laboratory there was a fine display of apparatus. The practical application of electricity in the transmission of power to a distance was illustrated by means of a turning-lathe driven by an electromotor, the current being supplied from a dynamo driven by a gas engine in the workshops, and conducted by wires to the motor. The drawing office, which was shown as in general use, was lighted by 10 candle-power incandescent lamps, one to each table, suspended from the roof by a method designed by Mr. Reid, which allows the lamp freedom of movement in every direction over the table, thus avoiding shadows. The lamps are supplied with current from secondary batteries. The instruments designed by Prof. Ewing for measuring earth movements on Ben Nevis were exhibited in the corridor, and carefully inspected.

THEORY AND APPLICATION OF THE TELEPHONE.

A lecture on this subject was recently delivered in the Burgh School, Kirkcaldy, by Mr. Townsend, district manager of the National Telephone Company for Fifeshire. The lecture was illustrated by apparatus and experiments. The lecturer began by referring to the early means of communication, and gave a short descriptive sketch of the origin and development of the telegraph. He then said the idea of transmitting the tones of the human voice from one place to another by artificial means is not of recent date. We are told that the Chinese, that wonderful race of people in the east, claim to have invented the telephone, and they do so on the strength of a book written by one of their ancient philosophers. The Persians said that the telephone had been for ages the toys of their children, and it has been found that the telephone of the Persians was identical with what is now called the "mechanical telephone." Two small cylindrical boxes are connected together by means of a tight string, and when speech is uttered into one of the boxes it is reproduced in the other. Its mechanical difficulties, however, prevent it being brought into practical use, and it therefore cannot be compared with the electrical telephone. The electrical telephone was invented by one Phillip Reis, a teacher of natural science in Germany, in 1861; but he was not successful in bringing his instrument before the public, and it was not till 1874, nearly twenty-four years after, that the subject received the serious consideration of scientists, and which has resulted in the perfection of his most wonderful instrument, which is destined some day to have the most civilising influence which it is possible for any invention to exert. In 1876 Alex. Graham Bell, a native of Edinburgh, then resident in America, and Professor of Vocal Physiology in the University of Boston, so improved upon it as to make it a practical success. This instrument, which Mr. Bell devised and sent to the Philadelphia Exhibition in 1876, caused a great sensation amongst scientific men, and Sir W. Thomson, who was present, proclaimed it "the most interesting of scientific inventions made in the history of science." The outcome of this perfection has been the establishing of what are called telephone exchanges, and now there is not a city or town of any importance but has, or is going to have, its telephone exchange, and to-day, out of the half-dozen towns in Scotland where the telephone is already established, Kirkcaldy is one of the most promising. One special advantage of the telephone is its great utility in cases of fire. Most large cities have their fire appliances on a large scale, but in comparatively small towns like Kirkcaldy no such system is required. The lecturer then described a fire alarm system as fitted up by the National Telephone Company in Inverness, where it had been of immense advantage. Loud sounding bells were placed in each fireman's house, and connected by wire with an instrument at the police office, which was under the control of the officer there. When a fire occurred in any part of the town a signal was given to the officer at the police office, either by telephone or otherwise, who immediately turns a handle attached to the fire instrument, which at once sets all the bells in the firemen's houses ringing, who know to come at once to the fire station. By this means the brigade can be called out in five or six minutes.

SOME POINTS IN ELECTRICAL DISTRIBUTION.

BY PROF. GEORGE FORBES, M.A., F.R.S.E.

(Concluded from page 298.)

SECONDARY GENERATORS.

I now come to speak of secondary generators, and since the principles which regulate their action are rather novel, it may be well if I spend a little more time in describing their action than I would otherwise do in a lecture treating chiefly of the manner of laying main conductors.

Everyone knows the principle of the induction coil. It consists of a core of iron surrounded by a coil of insulated wire called the primary coil, and by another one of insulated wire called the secondary coil. The secondary usually contains a large number of turns and finer wire than the primary. The current in the primary is alternately made and broken by a simple automatic means. This magnetises and demagnetises the iron core. This is equivalent to introducing and withdrawing a magnet into and out of the secondary coil and sets up currents in the secondary coil.

The electromotive force created in each turn of the secondary coil is measured by the number of magnetisations per second, and by the strength of the magnetisation. The latter is generally proportional to the number of turns in the primary, and to the current flowing through it. Thus the electromotive force in the secondary coil depends (1) on the number of turns in the primary; (2), on the number of turns in the secondary; (3), on the strength of the current in the primary; and (4), on the number of makes and breaks in the primary current. Thus by having a large number of turns in the secondary coil, and a small number in the primary, a very high electromotive force can be obtained from a small battery connected with the primary. If, on the other hand, a high tension interrupted current were sent through the fine wire coil we could get a large current from the thick wire coil.

Now, to feed a number of glow lamps in parallel, we require a large current, but this requires a large conductor. Here it was proposed to use a high tension alternate current (which acts just like an interrupted current) by a thin conductor from the works to the place of consumption, and there to transform it into a current of large quantity.

Then, again, another idea was thrown out. This was to carry the alternate current by a thin conductor round a large district, and at intervals to pass it through the first coil of induction coils, using the second coil to supply the lamps. Thus we should have a high tension current disconnected from the service conductors, and furnishing them all with a low tension current.

Induction coils used in this way have been called secondary generators or transformers. The perfection of manufacture of such apparatus consists in getting a maximum of induction and a minimum of heating. This has been admirably accomplished in the generators of Messrs. Gaulard and Gibbs. Instead of wire, the coils are made of copper discs, or flat rings split at one point, and with ears projecting outwards at the split. These discs alternately belong to the primary and secondary circuit, and successive discs of each circuit have the ears soldered together in such an order as to make up a spiral. The iron core is, of course, made of iron.

Although the even discs belong to the primary and the odd ones to the secondary, it does not follow that alternate discs should be coupled together. We may couple the 1st, 5th, 9th, &c., together, and also the 3rd, 7th, 11th, &c., so as to form two secondary circuits, which may be combined in parallel. The number of possible modifications of this sort is very great.

When the primary coil is magnetising and demagnetising the iron core, the latter sets up a counter electromotive force in the coil, and thus the current is largely diminished. But when there is no external resistance in

Digitized by Google

the secondary coil, that coil being short circuited, then any magnetisation and demagnetisation of the core starts a current in the secondary coil, opposite in direction to that in the primary and almost equal to it. Thus the iron cannot get much magnetised, for it is surrounded by two opposing currents almost equal in amount. In this case, therefore, the primary has little or no counter electromotive force opposing it, and consequently it flows more freely. This explains a thing which often puzzles the beginner, viz., that with a constant electromotive force in the dynamo the current in the primary is stronger when the secondary circuit is closed than when it is opened.

Very little energy is expended in magnetising and demagnetising iron wires. Thus there is really no loss of energy in the transformation, except that due to the heating of the conductors of which the coils are constructed, which is equal to the square of the current multiplied by the resistance. The loss of energy, which could not be accounted for, has been shown by Prof. Ferraris to be less than 1 per cent., and the practical efficiency of the generator amounts to as much as 95 per cent.

The theory of the secondary generators is very like that of the alternate current dynamo, if the reversals of magnetism of the armature were given by reversing the currents in the field magnets instead of by mechanical motion.

Coming now to distribution by secondary generators we find we must use the same principles as in direct distribution.

Parallel Distribution.—Let us take this case first. To do this economically we might lead two thin wires over the district and couple secondary generators to them. The condition of being able to have constant electric pressure in the lamps is that the electric pressure at the terminals of the primary should be constant. Here we meet the same difficulty as was experienced in direct supply. Consider three generators—1, 2, 3, Fig. 1. If the lamps are all on in all three cases then the pressure

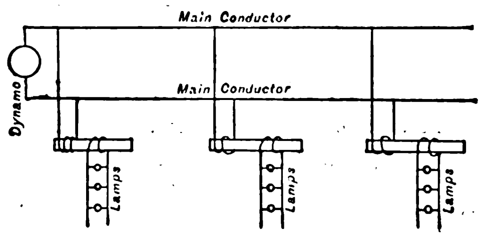

Fig. 1.—Secondary Generators in Parallel.

for No. 3 is less than for No. 2, and that again is less than for No. 1. Suppose you try to rectify this by using lamps of lower pressure at the far station. In this case suppose the lamps in No. 2 are extinguished, then the pressure in No. 3 will go up and tend to injure the lamps. If you try to correct this at the central station you will lower the pressure of No. 1 till perhaps it only burns red. This difficulty is exactly the same as in the direct service. The remedy is of the same kind. You must use the generators as distributing boxes (see my Cantor Lectures, 1885), with separate wires from the engine to each generator, each one being fed with a different pressure from the engine house. Fig. 2 shows this arrangement.

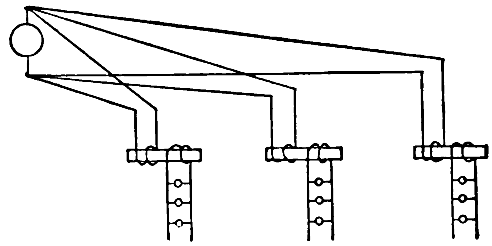

Fig. 2.—Distributing Boxes replaced by Secondary Generators.

There is no objection to it except (1) that you must use a large number of conductors, and (2) you introduce the full pressure of the high tension current into each house.

Finally, we come to distribution by generators in series. Here we have the best effect. A single wire (Fig. 3) goes round the circuit; if a double

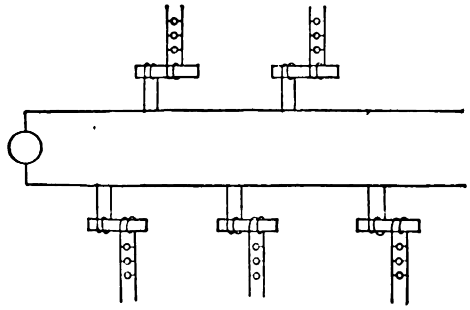

Fig. 3.—Secondary Generators in Series.

wire is used to prevent affecting telephones, it is half the weight, and generators are alternately put on one wire and the other all round the district, and each pair of wires ends at a point far from the station. Suppose we use 10,000 volts, we may have 100 generators in series, each using 100 volts, or we may make any other arrangement. If it were done as I say, then following out the data of my Cantor Lectures, a wire of one square inch section will carry current enough for 100,000 lamps each consuming 60 watts.

In this arrangement we must send a constant current through the circuit. This is actually done by the introduction of resistances. It ought to be done either by an electric governor on the steam engine or by compound winding the alternate current machine, a matter about which there is no difficulty at all.

But how are we to attain to constant electric pressure in the lamps when we have got our constant current? This is a problem which has puzzled many people, and many have come to the conclusion that it is impossible to do it without mechanism. This used to be done by automatically introducing the iron core farther or less far into the coils. It is now done without any relative movement of the parts. This is the last triumph which has been added to a series of laborious experiments which year by year have brought us nearer to a solution of our difficulties. I am not at liberty to explain the *modus operandi*, but I have seen it at work, and it is very satisfactory.

The theory of secondary generators has been so little studied, except by specialists, that I have thought it might be advantageous to many if I added to this paper the formulæ which represent the electric current and pressure as depending upon the resistances and mutual induction of the various parts. These data will be found in the appendix published on next page.

I do not think it would be consistent with the objects of this paper to describe the specific differences between different kinds of secondary generators, or to attempt to give reasons for choosing one of these forms rather than another. I would merely draw attention to the brilliant experiments on self-induction by Prof. Hughes, described in his introductory address as president to the Society of Telegraph-Engineers and of Electricians. Prof. Hughes has discovered a new and hitherto unnoticed source of waste of energy in self-induction, to remedy which it is essential to have the coils of the secondary generator made of discs.

I should also like before leaving the subject to dispel a growing error from the minds of some electricians. In speaking of different secondary generators, some persons are in the habit of speaking of one inventor's generator being used on a parallel system, another on a series system. This distinction is quite illusory. A generator made on any system is equally suitable for all kinds of distribution, and if an inventor states that his generator is only suited for one system of distribution, he displays his ignorance, and shows that he has yet much to learn before he can say he understands the theory of secondary generators.

Last year, when speaking in my Cantor Lectures, I said that the Grosvenor Gallery installation would be followed with interest by engineers. I considered that it was a new test. Up to that time the method had been applied only to light districts where the number of lamps was constant. It was not proved that the method was suitable to the cases where lamps might at any moment be extinguished. Two things were necessary for this—regulation of the current from the dynamo, and automatic regulation of the electric pressure in the secondary circuit. Neither of these had then been accomplished in a manner which satisfied me, and I certainly considered it was a very bold step on the part of Sir Coutts Lindsay to adopt a system which was then so imperfect.

I am satisfied now that self-regulation of the secondary circuit is sufficiently perfect for practical purposes, even when the generators are in series; and I have pointed out to Messrs. Goulard and Gibbs a further development which, in my opinion, will make their system even more perfect. The one weak point in the Grosvenor Gallery installation is the regulation of the current from the dynamo. Out of the four or five different methods by means of which this can be done, the worst has been applied up to this time, viz., hand regulation. The result is a frequent flicker in the lights. Still, when we consider that seven miles of route have been covered by the wires of this small association, and that on the whole great satisfaction is expressed by the users of the light, I must say that Sir Coutts Lindsay and his friends are to be congratulated on the great steps they have made towards success.

In conclusion, I wish briefly to allude to the present condition of electric lighting, and the prospects of economical distribution from central stations.

I have always maintained that there were three causes which retarded the progress of electric lighting:—(1) Financial speculation; (2) the Electric Lighting Act of 1882; and (3) the unsuitability of the schemes of electrical distribution propounded by the contractors. I will say a few words on each in turn.

From the year 1881 to 1883 this country was the scene of a most senseless speculation, started by clever men of business, who took advantage of the interest in electric lighting caused by the Paris and Crystal Palace Exhibitions, and supported by dupes whose ignorance of electrical matters was only equalled by their want of common sense as business men. These men combined to purchase for large sums the right to use the apparatus of some particular manufacturing firm in a special locality. They never asked any competent person whether this firm's apparatus was better or worse than that upon which there were no royalties to pay. Those who were not clever enough to get out of the affair before the bubble burst were the sufferers, and the consequence was a panic in connection with electric lighting which has hardly yet subsided.

With matured knowledge confidence is again being restored, because the public learn from competent and disinterested persons that economical electric lighting can be accomplished without the necessity for paying the heavy royalties formerly demanded.

I trust that the warning of 1882-3 will not be lost on financiers, and that they will not be misled by untried but tempting schemes unsupported by capable men of science.

Digitized by Google

The next cause which has deterred electric lighting is the Act of 1882. This is an Act to give undertakers the right to break up streets in order to lay conductors, under certain conditions. It is these conditions which are so unjust. Some of our legislators, looking at the monopolies which exist in gas supply, are afraid that electric lighters will raise another monopoly. Consequently they determined to hamper the electric lighting industry with conditions different to those imposed upon gas, and more stringent. They succeeded well, for they laid down such conditions that no sane man would invest in such a speculation. You would have thought it natural, I doubt not, that if the gas monopoly was truly so very irksome, the encouragement of a rival illuminant would have been the best cure for the evil, whereas our legislators acted as if they were parties interested in maintaining the gas monopoly, for they imposed such restrictions as rendered it impossible for electricity to be supplied to the public. Let me name one of their wise provisions. At the end of 21 years the local authority can, if they please, buy from the company supplying electricity the whole of their plant at the price of old material, without paying a farthing for goodwill or future profits, or past expenses in experimental and unprofitable work.

If, then, a company, after 21 years, were just making headway, and paying a dividend of 5 per cent. on their capital, the corporation would buy them up for perhaps a third of that capital, and get 15 per cent. But the case is even worse if the company is not yet earning a fair dividend, for then the corporation may hang over the company like a usurer over his victim, and each seven years it has the right to purchase the plant or not, and on the same terms as before.

Now, I agree with those who contend that electricity should be allowed to compete with gas under the same disabilities, and with the same advantages. This is not doubling a monopoly; it is splitting it into two, and destroying the monopoly, by allowing competition. If our legislators are not trying to uphold the gas monopoly they must take this view. In any case the public have shown that they will not submit to be deprived by legislation of this illuminant. The Board of Trade, I hear, have perceived their error, and are prepared to yield a little; but if they do not enable us to have electricity supplied to us, we, the public, must force their hand.

Still electric lighting is not quite dependent on this Act. Local authorities have no penalties, and I would strongly urge them to take the matter up, for we have now arrived at a stage when it is safe and profitable to establish electric lighting on a large scale.

Again, you must remember that the disabilities of the Act apply only to those who lay their conductors underground and wish to break up the street. Sir Coutts Lindsay has taught us how to defy the Electric Lighting Act by passing the wires overhead. Those wires do not suffer like telegraph wires in snow storms, for the electric current melts the snow.

The third cause, which deterred the progress of electric lighting, was the unsuitability of schemes of distribution which were proposed. I was impressed with this weak point at an early date. Sir William Thomson was the first to touch on the matter when he announced his law of the economical size of conductors. But the engineer had no tables to guide him as to the safety of these sizes of conductors in the matter of heating. I first attacked this problem in order to clear the way for scientific methods of dealing with distribution. In a paper read before the Society of Telegraph-Engineers and of Electricians, in 1883, I computed from the facts well known to physicists, the heating of different sized conductors with different currents, whether the conductors were bare, insulated, or buried. I had already, in a communication to the British Association in 1882, shown by experimental evidence, that the generally accepted laws required modification when we dealt with small wires.

The way being thus cleared, I attacked the problem of distribution generally, studying the various schemes which had been proposed or put in practice. My conclusions were published in the Cantor Lectures in 1885, and the most useful result was to announce a series of definite rules which must be attended to in order to provide an economical distribution. Since then some progress has been made, and the present paper will, I hope, bring the subject pretty well up to date.

The work which I undertook has been laborious, but it has been a very humble effort. I have brought forward hardly a single fact which could not have been foreseen by the competent engineer. But I think I have saved others from wasting their energy in repeating much of the work, which is laborious; and I also trust that the outcome is a set of rules to guide those engineers whose purely scientific knowledge may be a little defective from falling into the gross errors which have been so apparent in nearly all attempts at lighting by electricity on a large scale which have been made in the past.

I now close the subject for a time, and if the labour I have bestowed upon it leads in any slight measure to establishing one department of electrical engineering on a sound scientific basis, I shall feel that in the work I have undertaken I have been of some little use to my generation.

Appendix.

The following formulæ give the currents and electromotive forces, on the assumption that the magnetism of the core varies as the sum of the currents in the two coils.

The E.M.F. of the dynamo is assumed as being—E sin. mt

Then the primary current $= \mathrm{I} \sin. (mt+\gamma)$

secondary current $= \mathrm{I}' \sin. (mt+\gamma')$

$$\mathrm{I}^2 = \mathrm{E}^2 \frac{\mathrm{C}^2 + r'^2}{r^2 r'^2 + (r+r')^2 \mathrm{C}}$$

$$\mathrm{I}'^2 = \mathrm{E}^2 \frac{\mathrm{C}^2}{r^2 r'^2 + (r+r')^2 \mathrm{C}^2}$$

Where C is a constant;

r = resistance of primary circuit;

r' = ,, secondary circuit.

Also the potentials at primary terminals $= v$;

and ,, ,, secondary terminals $= v'$;

where $v = \mathrm{V} \sin. (mt+\phi)$

$v' = \mathrm{V} \sin. (mt+\phi')$

$$\mathrm{V}^2 = \mathrm{E}^2 \frac{\rho^2 r'^2 + (\rho + r')^2 \mathrm{C}^2}{r^2 r'^2 + (r+r')^2 \mathrm{C}^3}$$

$$\mathrm{V}'^2 = \mathrm{E}^2 \frac{(r'+\rho')^2 \mathrm{C}^2}{r^2 r'^2 + (r+r')^2 \mathrm{C}^2}$$

ρ and ρ' being the resistances of the primary and secondary coils.

Discussion.

The Chairman said he had listened with great interest to Prof. Forbes, and thought that his paper pointed out the way to the electric lighting of the future. There were many authorities there that night on electric lighting, and he thought they could not do better than to take theoretical principles first, and invite Prof. Hughes to give them his ideas on the subject.

Prof. Hughes, F.R.S., said in his latest researches he had found that the maximum induction in iron took place when the iron was in the round form. If it was flattened, so that the contiguous portions of the current became separated from each other, the current was very weak; it had not one-tenth of its previous capacity. In the case of copper wire flattened, the reduction in the self-induction was about 50 per cent. Taking iron wire and passing a current through it, if you wished to have a secondary current parallel to it, the self-induction prevented the current acting on the secondary coil; in fact, the force of the electric current was used up in doing internal work. By flattening it, it reacted on another wire to its full force, so that the energy which would have been used in self-induction was transformed into the secondary current. He had not the slightest doubt that if this method were adopted, enormously more power could be obtained from the secondary coil. When two wires were flattened, the portions contiguous to each other did not react on each other with the same strength, but reacted on any portion near; consequently, when there was another flattened sheet superposed, you had it in the nearest possible proximity. It was very remarkable that the same results at which he had arrived theoretically should have been wo.ked out experimentally by Messrs. Gaulard and Gibbs, and they had arrived at the best possible conditions he could conceive for constructing a secondary coil. He had only one fault to find with it; the generator itself seemed perfect, but it required intermittent currents, and, therefore, it seemed to him there must be a loss in the line. He had been much interested in the paper, and hoped Prof. Forbes would continue his investigations on this subject, which he had made peculiarly his own.

M. Gaulard (who spoke in French) said he was glad to say they had conquered all the difficulties which had stood in their way. The results of their later experiments had been eminently satisfactory. Their apparatus was constructed with two parallel circuits, forming spirals in the same direction. In order to obtain in the secondary circuit a variable electromotive force, they had contrived to unite in parallel and inverse directions the two circuits, and they had found that if in these conditions they sent through them an alternating current, the difference of potential at the ends of the spirals was directly proportioned to the resistance in the leads. If, on the other hand, they interposed in one of the connections a resistance, they found that the difference of potential at the two ends of the secondary circuit was, to a certain extent, directly proportioned to that resistance. From these observations it followed that if the leads consist of two parallel wires, and currents in opposite directions are sent through, not only no phenomenon of induction on the outer external circuit can appear, but no self-induction on these two leads can exist any more. He then detailed some experiments recently carried out by his firm, which proved conclusively the absolute non-existence of self-induction. He thought they might claim to have solved the problem of the transmission of force by electricity.

Prof. Hughes expressed himself quite satisfied with M. Gaulard's explanation. He was not aware that parallel circuits were used.

Mr. Gisbert Kapp, while having nothing to say on the subject of the distribution of electricity, said he would venture to add one more item to the list of improvements in machinery and apparatus. If they were to distribute electricity for the purpose of domestic lighting it was a matter of vital importance that a breakdown should never occur. The best way to prevent a breakdown was to drive at moderate speeds. The present tendency was now in this direction, and they were endeavouring to reduce the speed of their dynamos by making use of stronger fields and better methods of construction. He thought that with reduction of speed the chances of a break down were enormously diminished.

Mr. Drake recounted the advantages possessed by secondary batteries for general lighting purposes. In regard to the secondary generators, he thought that not only would any irregularity of the engine be transmitted to them, but that the variations due to inequality of consumption of different points of the circuit would also be noticeable. As to an indicator for cutting out any number of cells, he thought it was really not worth the trouble.

Mr. Shoolbred said that in regard to the condition of secondary cells it was stated that a hygrometer gave some solution to the question. He should be glad to know Mr. Drake's experience in this direction.

Mr. Drake was understood to say that the available space in the cell was of too limited a nature. The hygrometer required to be floated, and

Digitized by Google

this would entail an increased bulk of acid. Such, at all events, was his opinion.

Mr. SHOOLBRED: Then you are not practically acquainted with this question?

Mr. DRAKE: No, not practically.

Mr. SHOOLBRED then remarked that to the best of his belief Mr. Preece had obtained some gratifying results with the hygrometer in testing the condition of secondary batteries.

Mr. MORDEY then described an automatic regulator for maintaining a constant current in an electric light circuit. As to the secondary generators, he would ask Prof. Forbes if there was any advantage in using them in parallel circuits. Another point upon which he was not quite clear was the actual loss of energy in the core due to the rapid magnetisation and demagnetisation. There must be great difficulty in eliminating the effect of molecular action. In ordinary dynamos, where reversals of polarity were not very rapid, this difficulty was not felt, but in secondary generators, where the reversals amounted to several thousands per minute, it would seem possible to measure the loss of which he spoke.

M. GAULARD said that the loss consumed a small portion of the total energy, but had no mischievous effect whatever.

The CHAIRMAN said that as a matter of fact the electric light industry was not rushing on so fast as they could wish, but it must be remembered that two or three years ago they were in absolute danger. False steps were made, and now some of those who had been foremost in the movement had gone. Prof. Forbes, in his Cantor Lectures and in his paper that night, had shown them the results of much care and thought. They might now be said to be in a more stable position as regards this matter than they had ever been before. When with storage batteries they could get 70 or 80 per cent., it became evident that great progress had been made in the construction of this apparatus. In regard to secondary generators, he thought that the successful experiment made by Sir Coutts Lindsay and the experiment made some time ago by MM. Gaulard and Gibbs in the lighting of the Edgware-road Station and a portion of the Notting Hill-gate District were also evidence of progress. The system was a good one then, and it was now a better one by far.

Prof. FORBES, replying to the questions which had been raised, said that there was but little left for him to answer. Mr. Kapp had pointed out the importance of decreasing the speed of dynamos. He congratulated Mr. Kapp upon decreasing the speed of his dynamos, but he congratulated him still more upon increasing the magnetising induction. There were, it was true, fewer chances of a breakdown with his machine; but at what a cost had this been bought? It was a grand machine, weakened by slow speed—a giant crippled. For central stations its slow speed was advisable, and the only way to get a proper effect was by increasing the size. In regard to Mr. Drake's remark on secondary batteries, he thought it would be a serious drawback if they could not be made without attendance. Mr. Drake had suggested the idea of the master cells to him (Prof. Forbes). Mr. Mordey had asked what advantage could accrue from using secondary generators. There was this advantage, that with the primary circuit in series and the secondary circuit with the discs in parallel it was possible to have a current of something like 10,000 volts in the primary circuit and 100 volts in the secondary circuit. Any desired variation could be made. The loss of energy in magnetisation and demagnetisation was, as M. Gibbs had told them, an extremely minute quantity, and when iron wire was used could not be detected.

The usual vote of thanks concluded the proceedings.

LEGAL.

The United Telephone Company v. Bassano and Slater.

In the Court of Appeal on Wednesday, before Lords Justices Cotton, Bowen, and Fry, an application was made by the plaintiffs in this action to dismiss for want of prosecution an appeal presented by the defendants from the judgment of Mr. Justice North, on August 12 last, restraining the defendants from infringing the plaintiffs' patent of July 30, 1877, for the Edison transmitter for telephones. The trial of the action, on the 13th of July last, was reported in *The Electrician*. On the 12th of August Mr. Justice North gave judgment as above stated, and also ordered the defendants to deliver up certain instruments which were in their possession. The learned judge, however, postponed stating his reasons for his judgment, and he has not yet stated them. On September 23 last the defendants served notice of appeal. On December 4 a receiving order in bankruptcy was made against the defendants on their own petition, and in consequence of this the appeal could not be brought on in its proper turn. The plaintiffs on the 19th inst. gave notice of motion that the appeal might be dismissed for want of prosecution.

Mr. ASTON, Q.C., and Mr. MICKLEM, for the plaintiffs, now moved accordingly.

Mr. CLAUDE PLUMPTRE, for the bankrupts and the official receiver, urged that until the learned judge had stated his reasons for his judgment it was impossible for the official receiver or the bankrupts to be properly advised as to the prosecution of the appeal. The official receiver would have a *locus standi* by reason of the order for the delivery up of the instruments.

Mr. ASTON replied.

Lord Justice COTTON said that the application was of a somewhat novel character. If the official receiver was carrying on the business of the bankrupts he would be interested in the injunction. And, notwithstanding the bankruptcy, the bankrupts were also interested in it, because it prevented them from carrying on their business by the work of their own hands, and if they committed a breach of it they would be liable to be sent to prison. The Court had ascertained from Mr. Justice North that he would state his reasons within a short time, and they thought that the proper order to make would be this—that if the bankrupts did not within a fortnight after Mr. Justice North had stated his reasons give security to the amount of £100 for the costs of the appeal, or the official receiver did not within the same time make himself a party to the action, the appeal should, without any further order, be dismissed without costs. If within the fortnight the bankrupts should give the security, but the official receiver should not make himself a party, the appeal would proceed as that of the bankrupts alone. On the other hand, if within the fortnight the official receiver should make himself a party, but the bankrupts should not give the security, the appeal would proceed as that of the official receiver alone.

COMPANIES' MEETINGS.

The Maxim-Weston Electric Company (Limited).

The fifth annual ordinary general meeting of the shareholders of this Company was held on the 19th inst. at the City Terminus Hotel, Cannon-street, Mr. Hugh Watt, M.P., presiding.

Mr. JOHN WRIGHT (the acting secretary) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said it was now a year since he had had the pleasure of addressing the shareholders in general meeting. Since then they had found it necessary to meet on two separate occasions, and he thought he need not refer to the object of those meetings beyond stating the fact that immediately afterwards they secured the sanction of the Court to the resolutions which had then been submitted, passed, and confirmed by the shareholders. They secured that without the necessity of adding the word "reduced" to the title of the Company, as was sometimes insisted on. On the last occasion, just a year ago, when he addressed them, he ventured to enter *in extenso* into the past history of the Company. At present he did not think it necessary or desirable that he should do so. He trusted that as long as they held the position they now did they would learn what lessons they could from the past, and endeavour to utilise them for the advantage of the Company in the future, and he did not believe it would be either wholesome or desirable to go just now into the early and unfortunate history of the Company. He did not think he need say that the financial position of the Company to day was stronger than it had ever been. The cash reserve at the bankers and on deposit was sufficient to prove the fact, and, in view of their improved condition, he thought the Directors were warranted in submitting a recommendation as to the payment of a dividend. He ventured at an extraordinary meeting, after the business for which the meeting was convened—the only business which could legally be transacted at that meeting—had been closed, to submit a short statement as to the position of the Company, the contracts which had been carried out or were in progress—a short *résumé* of their proceedings, in fact, up to that date. This naturally left him very little to say to-day. The proposal that a suggestion should be made from the other side of the table with regard to the amount of dividend which they were entitled to, and ought to pay, led to the Board making the recommendation which they would do, namely, to pay a dividend of 7½ per cent. upon the present amount of capital. As he supposed he might assume that most of the hon. proprietors whom he had the pleasure of addressing were business men, it was quite unnecessary for him to go into the general question of trade depression. They were all, he was afraid, only too familiar with that subject. It must, therefore, he thought, be to some extent gratifying to the shareholders of the Company that, passing through such a crucial period as they had done last year, the Directors were able to come before them with a substantial profit, after paying all legitimate and working expenses. In connection with another company he saw the other day that a noble lord ventured to state what must be encouraging to all investors in electric lighting enterprises—namely, the fact that electric lighting generally was improving. He (the speaker) had much pleasure in endorsing this opinion. It was not only improving, but they had inquiries from all parts of the world for installations. They had orders from nearly every colony, and had found them a more lucrative field than the home markets, containing, as they did, such a plethora of dynamos and other plant of almost every manufacture. The directors had, therefore, occupied their attention during the past year to a large extent with colonial and foreign trade, and during the last two months had made several of the largest shipments of electric lighting plant upon order that had ever been made, he supposed, from this or almost any country. During the last twelve months he was happy to say that, though their books did not show a largely increased value of plant sold to that of the previous year, they turned out in weight—that was in machines, lamps, &c.—a very much larger amount than in the preceding twelve months. The reduced sale price of the plant was owing to the amount of competition to which they had been subjected. Last year, in speaking to them he ventured to express the hope that they might be able to secure continued good prices and a larger volume of business. This, however, did not turn out to be quite the case, and he had no hesitation in confessing that the position of the Company to-day, and the amount of business they had been able to transact, were not up to his expectations. He did not know at that time that other companies who were on the verge of liquidation, and who had since unfortunately gone into liquidation, had such a large amount of plant on hand, the result being that of course the liquidators of those companies in winding up their affairs had to submit to auction an enormous amount of material. That naturally depressed very much the enterprise for the past year. At the same time he had pleasure in stating with regard to the patents held by this Company to date, they were still in the forefront, and he did not think any better lamp had yet been discovered, although they had from day to

Digitized by Google

day and from month to month been kept upon the tenterhooks of expectation of something coming out which would entirely eclipse the Maxim-Weston. So far, nothing of the kind had happened. They had continually gone on experimenting with, and improving upon, their patents, and partly with a view to that they were on the eve of taking a larger factory, where they would be able to manufacture not only what they were at present doing, their own dynamos, but all the plant of the Company, excepting only incandescent lamps. With regard to these he had concluded such an arrangement with the American Company as would meet their requirements, for he did not think it would be possible for them to go to the expense of laying down special plant for incandescent lighting, and the carrying of it out for the same price to which he had been able to squeeze down the American Company. He might also say, as he had referred to the present company in America, that so far that company had met them very fairly. The only difficulty they experienced during the last few months had been the inability of the American Company to supply them with sufficient despatch with the plant that had been required. This was owing entirely to the enormous development of the business in the United States of America, where there were £2,000,000 or £3,000,000 profitably employed in the manufactures and in the installations of sub-companies of the American Company throughout the Union. This he thought was a sufficient guarantee that their plant was all that it was promised to be when the present Directors took it over, subject to such improvements as they had made. During the present year he hoped they would be able to considerably improve their arc lamp plant. Their efforts hitherto had been mainly directed to endeavour, by means of experiments, to secure better results—that was to say, to enable them, through the same dynamo, to run a larger percentage of lamps, which of course proportionately cheapened the machine. In that way they had been able to a great extent to maintain the price of their various machines by securing, through winding and otherwise better results in the number of lamps. He hoped during this year they would be able, by undertaking the manufacture of this plant, to save something like 20 to 30 per cent. upon the present cost price of machines to them. This was a very material matter, because during the last two months he had been negotiating with almost every country in Europe, over and above the colonies, with the view of increasing their business. The result of those negotiations in a great many cases had been to prove that the prices charged them by the American Company virtually put them out of the market in competing with rivals on the Continent. He was in hopes, by means of larger premises and the improved results which he thought they would obtain within the next three months in connection with the arc lamp, to be able to compete at a good profit with their Continental opponents, whose material was cheaper, whose iron and labour were cheaper, and whose expenses in connection with manufacture were not nearly so high as they were in England. If they could manage to compete in countries like Germany it was all, he thought, they could hope to attain with regard to the cost price of their plant. He might mention that they had not secured the premises referred to in the report, but after a great deal of trouble and inquiry on their part they hoped to save about £200 a year in the rental of the premises they were trying to acquire, and which would afford accommodation to the extent of 8,000 or 10,000 cubic feet. Their system, he was happy to say, was growing in favour, and the Maxim-Weston installation had given the greatest satisfaction. The last installation completed had been in connection with the Post Office. He was gratified to say that, after numerous experiments, first of all directed to secure a non-flickering light by means of a gas engine, they had succeeded—he thought he might say, in all humility, the first time in the history of electric lighting companies. Their next object was, by a subdivision of the light, to obtain the greatest and most varied results at the lowest cost, for this really, after all said and done, was the great desideratum in regard to electric lighting which they were all hoping to attain in their competition with the greater power, gas. In connection with the Post Office department and the savings' bank department, they had to contend with the difficulty of switching on and off from one room to another, and if they managed this in the case of 36 different circuits from the same machine, they would effect an economy varying from 30 up to 60 per cent. They had no data to go upon; but had simply to wrack their own brains, and find out, by means of a switch-board, what would answer all purposes to arrange from three machines a switch of 36 circuits. With the manager of the works, who was a man second to none in his profession, after some two months' time they had designed a switch-board, which the officials of the Post Office, including one of the best known electricians of the day, Mr. W. H. Preece, told him was entirely successful. They were met by the chief men connected with the postal department to investigate this installation. It was the first run, and, of course, the first run was not often the best, but Mr. Tough was so satisfied with the switch-board that they allowed the officials to be present at the test trial. The result was entirely successful, and after two or three hours' running the Post Office authorities were pleased to express their entire satisfaction with, and to pass the installation. He might mention that they had entered into an agreement with the Post Office to run it for two years at a very handsome rental, thereby in a great measure guaranteeing the efficiency and the durability of their plant, a point they naturally set a good deal upon with regard to the future.

A SHAREHOLDER: Are they incandescent?

The CHAIRMAN said that the installation was incandescent. There were at present 700 lamps running. They found that with the engines they used, three 40 horse-power Ottos—the largest gas engines in use—their machines required very much less power than those of any other system. They discovered, for instance, that two machines could be driven by the same engine, and would give them a maximum of 500 lamps. Consequently, the postal authorities, as soon as the details of the installation had been completed, intended, he thought he might say it in all confidence, to duplicate the installation. The only difficulty at present was with regard to a tenant whom the Post Office had arranged to buy out, and thus increase their basement accommodation. When that was done he believed he might safely say that the Post Office would give them a duplicate contract. That installation was the largest they had ever undertaken, and after the success which had attended it, in enabling them to switch off from thirty-six different rooms on to any of three machines, they were prepared to say that they could carry out lighting of the most varied character. They had done their best in the matter of increasing their agents, some of whom had got for the Company a considerable amount of business during the last few months. Whether it was from the fact that the repute of the Company was going up he did not know, but they had had applications from the first electrical agents throughout England and Scotland, with the object of representing the Company in their districts. Hitherto agents had been very much disposed to want all the profit to themselves. He had no objection to give an agent a fair commission, but he objected to allow to him the entire profit in view of the fact that this Company had expended about £140,000 in connection with their patents. He would now shortly review the report and balance-sheet, which he might mention he and his colleagues had endeavoured to draw up in as lucid a form as they could. The first paragraph referred to the fact that during the last two years no sum had been laid aside for bad and doubtful debts and other contingencies such as were referred to in Clause 75 of the Articles of Association. He wished to refer to this specifically, inasmuch as the Directors did not wish to utilise the fund they now had for any purpose unknown to the shareholders, and he might mention that in taking larger premises they would have to spend a good amount in putting up new fixtures and so on, which came within the meaning of the clause referred to. The Directors therefore decided to set aside the sum of £3,606 to the credit of a general reserve fund. As far as the present Board was concerned he was happy to say that during the last two years and nine months he did not think they had contracted £600 worth of bad debts. This, he thought, said something for the Board, because it was one thing to sell plant and quite another to get the money for it. They could have done a much larger business had they been content to take a certain number of risks which would have hardly been judicious with the comparatively circumscribed funds at the disposal of the Company. After setting aside the sum mentioned to reserve, the total balance at the credit of profit and loss account amounted to £5,284. At the last meeting the shareholders thought it proper to veto a proposal of his—which he made in perfect good faith—to declare a dividend. He had now no wish to dispute the wisdom of that decision; but to-day it enabled the Directors to recommend a dividend so much in excess of what it would have been in their power to do if they had not carried forward so large a balance last year. The Company was now in a position not only to warrant but to entitle them to pay a dividend, as the Directors proposed, of 7½ per cent. Of course the recommendation was entirely amenable to the decision of the shareholders, inasmuch as the payment and the amount of a dividend rested entirely with them. He need not dwell upon the next clause of the report, which referred to their having obtained the sanction of the Court to the reduction of capital, by which patents' account had been reduced to £35,000, which included outlays during the past year in connection with the new patents. The plant and machinery at the factory had been valued by himself, with the assistance of the work's manager, and he could vouch for the fact that it was all new, and in good saleable condition. Owing to the growth and requirements of the business, as he had said, they were looking out for larger premises, which would effect a saving of two or three thousand pounds to the Company in the event of their having to turn out a greater number of machines than they had done during the current year. They had encountered very great difficulties in connection with some of their staff. The electricians, however, were men who, he was happy to say, had been with the Company since he took the management of it, and they continued to give great satisfaction, and were, he believed, contented with their position. The *employés* were also of the opinion, he might say, that the Maxim-Weston patents were about the best in the market, and that the Company must in time attain a leading position. They had done considerably more business last year, although the profits were not much in excess of what they were a year before, owing to their having had to reduce their prices rather than lose orders from customers from whom the money was sure. As soon as the present Government got fairly settled down to business, and the perpetual question of Ireland was disposed of, he hoped to be able to induce the President of the Board of Trade to consider some suggestions which he (the speaker) hoped to have the pleasure of submitting to that gentleman. He did not quite anticipate, as did the chairman of another company, that electric lighting would immediately employ thousands of workpeople in this country, or that the profits from it would amount to millions of money. As a business man, he could not see how companies at present doing a small business relatively to the enormous capital invested by the public in connection with the electric lighting enterprise could all of a sudden be inflated like balloons and begin to make millions of money. He anticipated no such result. He had never been a pessimist, but he did not like to indulge in too glowing an account of the future of the electric light. It was like that of all other enterprises, uncertain; but, as far as they could see at present, the future of this Company might be assumed to bring to them a gradual development of business and steadily improved dividends. He did not think he had much to add with regard to the balance-sheet. The first item he had already explained. The second item—"machinery and stock at factory £12,285"—was put at a sum considerably under the sale price of to-day. The shares in the Electric Sun Lamp and Power Company (Limited) would, he believed, realise about the sum named. With regard to debtors, as he had explained at previous meetings, over a third of the amount was due by the British and Colonial Governments, and as

Digitized by Google

for the remainder, as far as they could make out, they were entitled to assume that it would be all realised. He had no anxiety with regard to the item. Cash at bankers and on deposit required no comment. Coming to profit and loss account, the expenses for the year amounted *in toto* to £3,630. Last year they stood at about £1,300 less. The excess had been mainly owing to an increase in their staff, and to travelling expenses, which had been somewhat heavy in consequence of their going about opening up new fields of enterprise, which he trusted would be valuable for the future, and the other ordinary charges. The amount to be carried forward, after the payment of the dividend, would be about £600. He concluded by formally moving the adoption of the report and accounts.

Mr. LOUIS SWABY said he had much pleasure in seconding the motion. Some three years ago, when the present Directors took over the management of the Company, they had no idea of the difficulties that they had to contend against. Even if they had failed to bring the Company to a successful position he would have considered it no disgrace; but he was happy to say that they had not failed, and he fully believed that the future of the enterprise was an exceedingly bright one. He was pleased to say that one of those difficulties was gradually passing away—he wished he could say that it had disappeared altogether—he referred to what he might call unfair competition. They had sometimes to allow contracts to go past them which other people were found willing to execute at a loss, but which this Company would not undertake except at a reasonable profit. He believed such work was called "exhibition work"—in other words, work done for the sake of advertisement. If this Company had gone in for exhibition work they must have very soon gone into liquidation, and from what he read in the newspapers he thought that other companies were coming to the conclusion that to do business for such a purpose was not a paying game. He did not think it would be right for him to sit down without giving credit where it was due, and he was sure his colleague, Mr. Brown, would bear him out in what he was about to say, by frankly stating that the success of the Maxim-Weston Company was wholly due to the efforts of the Chairman, who had had no light work in bringing the Company to its present position.

Mr. GRIFFITH asked if there had been or was to be any fresh issue of shares. If so, he thought that the present shareholders, who had stood by the Company so long, ought to have the first refusal of the new issue.

Mr. JACKSON wished to know whether it was necessary according to the Articles of Association to add annually something to the reserve fund?

A SHAREHOLDER suggested that it might be advisable in the interests of the Company to establish their works a little way out of London, where premises and labour might be obtained considerably cheaper than in the metropolis.

Another SHAREHOLDER drew attention to the large item which figured in the accounts as claims upon debtors, and desired to know whether any of the sum had been paid off. He thought that more details should be given as to the expenditure.

The CHAIRMAN, in reply, said that if it were the wish of the shareholders that a more detailed statement should be given, the Board would be only too happy to accede to the request in future. He did not wish to draw any analogy between the expenses of this and other companies, but it did not seem to him that the amount which had been spent in the conduct of so extensive a business, involving the payment of some thirty or forty workpeople, was a very large one. As to the debtors, he thought he had explained that the Company's business was transacted all over the world, and they must therefore perceive that in was impossible to receive from and execute orders for distant places without incurring a delay of at least six months in many cases before they could receive the money for them. He was happy, however, to say that they had received a considerable sum since the end of last year, and he hoped that before a month was passed to receive £3,000 more. Of course, in connection with Government contracts, they must be all aware that supplies were voted only once a year, so that he did not think that any Government contract could be undertaken without their having to wait nine or ten months before they received the money for it. He had the assurance of the chief officials of the Post Office that the Company would be paid, on account of the installation in connection with that department, over £2,000, being the balance remaining due to the Company, within three or four weeks. With regard to increased capital, he was happy to be able to inform the hon. proprietor that there had been no fresh issue. The Directors had no power to make one. A resolution passed on the 16th of May, 1884, was to the effect that no further issue of shares, beyond the 250,000 shares, could be made without the sanction of a resolution of the shareholders passed at a general meeting of the Company duly convened for the purpose. The present meeting, therefore, could not deal with the question even if it were raised, and certainly the Board could not deal with it. He was much obliged to the gentleman for the suggestion that they might, with profit to themselves, establish their works out of London. But he (the Chairman) thought that his own proposal to get new and cheaper premises in London was a better one. The Directors had duly considered the subject, and they had come to the conclusion that if they could secure the works for which they were now in treaty they could not do better in the interests of the Company. As to the wages of their *employés*, he thought they would compare favourably with those of any workpeople connected with any mechanical enterprise in the kingdom. The books of the Company were open to every shareholder. The Board had nothing to conceal, and if any of them would ask for information he would be at all times ready to furnish it. The reserve fund had been set aside purely for the objects he had named. There was nothing binding in the articles with regard to reserves. He knew very well that such a fund made a company sound very well for stock-broking purposes, of which he personally knew nothing. At the same time the Directors saw their way to declare what he ventured to think was a substantial dividend, and to reserve something to meet the contingent charges to which he had referred. He regarded it, moreover, as a prudent step to lay aside money in the event of their not being able to pay next year the same dividend that they did now. He personally believed, however, that they would be in a position to divide a much larger sum, which shareholders like himself in a Company which had been unfortunate at first and unfortunate in its procedure for more than a year, until the present Board took office, had a right to expect. He concluded by putting the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. BROWN, the dividend recommended by the Board of 7½ per cent. was declared.

The retiring Directors, Messrs. Watt and Swaby, were afterwards re-elected on the motion of Mr. GRIFFITH, seconded by Mr. JACKSON.

A resolution, proposed by Mr. GRAY and seconded by Mr. HILLIARD, fixing the remuneration of the Directors at £500, was subsequently passed, as was also a vote of thanks to the Chairman, which terminated the proceedings.

Swan United Electric Light Company (Limited).

The adjourned general meeting of the shareholders of this Company was held at the Cannon-street Hotel on the 23rd inst., under the presidency of Mr. F. R. Leyland.

The SECRETARY (Major S. Flood Page) read the notice convening the meeting, which intimated that it would be necessary to adjourn again.

The CHAIRMAN said he was sorry, in the unavoidable absence of the Chairman of the Company, to have to move a resolution for further adjourning the meeting. The negotiations which they had been having with the foreign companies were not yet settled, and, therefore, they thought it would be injudicious to hold their general meeting at present. They thought that the negotiations should first be settled either one way or the other. It was for that purpose that they proposed that the meeting for the consideration of the accounts and other matters should stand over until the 23rd of March. He concluded by moving a resolution to that effect.

Mr. W. C. QUILTER, M.P., in seconding the motion, observed that he did not think it was necessary for him to say anything more to convince the shareholders of the advisability of not having any discussion on the affairs of the Company during the continuation of the negotiations referred to, which must be more or less of a delicate character.

The CHAIRMAN put the motion, which was at once carried unanimously, and the proceedings then terminated.

NOTES.

APPROPRIATE.—A suggested word for "telegraphic address" is "telenym."

BOOKS RECEIVED.—"Manuale Teorico-Pratico dell' Elettricista," by P. Meardi, and others, Milan. The *Elettricita* Press.

THE TELEGRAPH IN SENEGAL.—According to *L'Akhbar* the telegraph line between Bakel and Matam is practically finished.

TOWN LIGHTING.—An installation of the electric light is now being put down in Salon, a small town in the department of the Bouches-du-Rhone.

THE ELECTRIC LIGHT IN BOSTON, U.S.A.—The mechanical engineering laboratory of the Institute of Technology is now lighted by incandescent lamps.

THE TELEGRAPH BATTALION.—A detachment of the Telegraph Battalion of Royal Engineers has been placed under orders for proceeding to Egypt.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, amounted to £48,814, against £61,784 in the corresponding period of 1885.

THE TELEPHONE IN BELGIUM.—The adjudication of the concession for the establishment and exploitation of the telephone system in the town of Malines has been postponed until the 31st inst.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of February amounted to £1,576, against £1,442 in the corresponding period of last year.

THE VAN RYSSELBERGHE SYSTEM.—It is reported that the Administration of Telegraphs in Switzerland have decided to adopt the Van Rysselberghe system of telephony on the line between Bâle and Zurich.

THE TELEPHONE IN BRISBANE.—The rapid increase in the number of telephones required throughout Brisbane has caused the Government to introduce the system of aërial cables patented by Siemens Brothers.

NEW SOUTH WALES MINISTRY.—The Agent-General for New South Wales has received a telegram from Sydney informing him of the formation of a new Ministry. The Hon. F. B. Suttor is the new Postmaster-General.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February amounted to £33,688, and to £40,114 in the corresponding period of 1885.

THE TELEGRAPH IN SOUTH AFRICA.—The use of the telegraph for the remittance of money is rapidly spreading. In 1884, 3,050 orders were issued for £18,139; in 1885, the number was 6,713, and the amount £40,182.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended Feb. 26, were £2,662, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

LONG DISTANCE TELEPHONY.—The experiments recently carried out with the Maiche apparatus between Paris and Troyes, a distance of about ninety-nine miles, are said to have yielded very satisfactory results. The trials will be repeated at an early date.

NEW PERIODICAL.—We have received the first number of a new monthly periodical called "Worthy Workers." It is at present on rather a small scale, but as the subject suggested by the title is a somewhat extensive one, we may hope to see this remedied later on.

TASMANIA.—The following are the submarine cable receipts for December:—Paid in Tasmania, £438, 13s. 5d.; paid elsewhere, £331. 4s. 4d.; total, £769. 17s. 9d. The number of messages during that time was 5,048, being the largest number yet despatched in a month.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 28th Feb. are £2,483, as compared with £2,515 in the corresponding period of 1885. The November receipts, estimated at £3,935, realised £3,996.

A NEW LABORATORY OF PHYSICS.—The old Tour St. Jacques la Boucherie, Paris, celebrated in connection with Pascal's experiments on atmospheric pressure, is now the site of a Laboratory of Physics. The inauguration took place on January 13. The tower was lighted by incandescent lamps.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of February was 3,402, estimated to produce £2,750, against 3,225 messages, producing £2,730, in the corresponding month of last year. The traffic receipts for the month of November, estimated at £2,250, realised £2,313.

THE ELECTRIC BLASTING COMPANY.—We are informed that this company has just successfully started a set of apparatus of G. B. Walker, Esq., at Wharncliffe Silkstone Colliery, near Barnsley, and has received an order for four sets of apparatus for blasting all shots fired in Harris' Navigation Colliery, Treharris, one of the largest collieries in Wales.

THE ELECTRIC LIGHT FOR WARSHIPS.—The "Collingwood" has been fitted with the electric light on the principle carried out on the "Impérieuse." She has no less than 420 lamps, the largest number of any ship in the service; and as the trials on board the "Impérieuse" proved so satisfactory, the trial of the lighting of the "Collingwood" is to be proceeded with forthwith.

POST OFFICE TELEGRAMS.—In the House of Commons on Monday night, Mr. H. H. Fowler, replying to Mr. E. D. Gray, said there was no regulation to the effect that when a telegram was sent from a local post-office to an address in the same town the name of the town should be inserted. At Belfast and Cork this insertion had been insisted upon, but instructions to the contrary had been given.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, S.W., on Thursday, the 11th inst., at 8 p.m., when the following papers will be read:—"Economy in Electrical Conductors," "Note on Magnetic Resistance," by Profs. W. E. Ayrton, F.R.S., and John Perry, F.R.S., members.

SIR H. D. WOLFF'S MISSION.—In the House of Commons last week Mr. Bradlaugh asked the Under-Secretary of State for Foreign Affairs to state the total amount of actual payments for telegrams to and from Sir H. D. Wolff, distinguishing those to and from Turkey and to and from Egypt. Mr. Bryce said the total cost of telegrams sent to Sir. H. D. Wolff was £772, and of telegrams received from him £3,192.

THE ELECTRIC LIGHT IN MANCHESTER.—The lamps, &c., at the new offices of the Lancashire and Yorkshire Railway Company, Manchester, are 1,300 in number, supplied from 4 shunt normal Wolverhampton dynamos. A set of accumulators is also provided to keep 120 lamps alight for three hours after engines are stopped, or for a greater length of time if

Digitized by Google

necessary. The lamps, we believe, are Woodhouse and Rawson's.

THE ELECTRIC LIGHT AND THE HOUSE OF LORDS.—In the House of Lords on Tuesday night Lord Limerick moved that a report of the evidence taken before a Select Committee with reference to the ventilation of the House be laid upon the table and printed. Lord Milltown suggested that the electric light should be introduced, as the machinery used for ventilating could be utilised for the electric light. The motion was agreed to.

TELEPHONE IN FRANCE.—In France, at the end of December, 1884, there were 3,534 subscribers to a telephone system which embraced nearly 4,000 miles of underground wires and about 33 5 miles of overhead wires. At the end of December, 1885, the number of subscribers was 3,983, the underground wires 4,320, while the overhead wires remained practically the same; thus the extension has been, as far as the lines are concerned, in the direction of underground wires.

A NOVEL IDEA.—One of the latest inventions with which America is to be credited is an automatic device for setting up type by electricity. By means of this apparatus and a synchronous telegraph the merry compositor in his hour of luxury or of debility may set up his copy at the office from the sanctitude of his domestic hearthstone. We commend this machine to the notice of foremen printers who yearn for quietude, and " comps. " who suffer from *l'embarras de richesse.*

SOME INTERESTING STATISTICS.—In America the amount of capital sunk in the electric light business is said to amount to 70,000,000 dollars. About 25,000 incandescent and 12,000 arc lamps are installed yearly. In the manufacture of glow lamps over six tons of mercury and 700 air pumps are now in use. The city of New York pays about threepence per hour for each lamp of 2,000 candle-power. To supply the arc lamps in the United States 300,000 carbons are manufactured daily.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—We are informed that the directors of this company declared, on the 3rd inst., an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended 31st December, 1885, and payable on the 25th inst. The books of this company will be closed from the 18th to the 24th inst., both days inclusive.—The traffic receipts of this company for the week ended 26th ult. amounted to £3,478.

THE BOISSELOT TELEPHONE. — According to our foreign contemporaries this telephone is characterised by several novel points of construction. The magnet is of charcoal iron, curved in a manner which is said to give great force in a small volume, and actuates a number of coils wound upon small Maiche armatures fixed at the bottom of the metallic case which encloses them. The coils, being independent, are said to possess great mobility and to be susceptible to very exact regulation.

BALL AT THE ELYSEE.—Advices from Paris state that the recent ball at the Elysée was, as usual, very crowded. More than four thousand persons attended. An incident of the evening was a glazier making his way into the State Rooms. He was able to do this because an usher fancied that he was employed to look after the electric fittings for the lamps in the chief ball room. The glazier strolled hither and thither, and then asked to see M. Grévy, with whom he said he had an appointment.

THE ASSOCIATED CHAMBERS OF COMMERCE AND THE TELEPHONE.—At the twenty-sixth annual meeting of these Chambers, held recently, the following resolution, proposed by the Hull Chamber, was passed:—"That in re-affirming the resolution of last year, the Executive Council appoint a deputation to wait upon the Postmaster-General to urge the necessity of a material reduction in the rental charges of telephonic instruments supplied to various towns in the United Kingdom."

MIDDLETON-IN-TEESDALE.—It is said a gentleman in this district has devised a method whereby the greater part of the valley of the Tees could be illuminated by means of the electric light. He proposes to utilise the High Force and the Caldron Snout for the requisite power, the vast water-pressure there, in his opinion, being at present totally wasted. The machinery to be erected at the waterfalls in question would be of such a character as not to disfigure the scenery. His plans and drawings are nearly completed, and, when ready, will be submitted to the public.

TELEGRAMS TO THE ROYAL COURTS OF JUSTICE.—The superintendent has issued the following notice respecting the transmission of telegrams to the Royal Courts of Justice, viz.:—Telegrams will be issued direct to the office No. 605 in the Royal Courts of Justice, and will be delivered therefrom by a messenger into the rooms indicated. The surname, number of room, and "Courts Justice" will be the recognised address for all town messages, "London" being added if sent from a country district. No title, initials, or christian name will be necessary, except only the latter where two officers of the same name occupy one room.

THE PICCADILLY RESTAURANT.—By the opening of the new Piccadilly Restaurant, an addition has been made to the already large number of sumptuous houses of entertainment at the West-end of the town. The building is situated upon the broad new open space at the beginning of the new thoroughfare from the eastern end of Piccadilly to New Oxford-street, and is at the south-west angle of the large block of solid masonry of which the new Pavilion Music Hall forms an important portion. The decorations are in the Italian style, and the whole building is lighted by the beautiful little glow lamps or incandescent electric lights.

TABLE LAMPS.—The Woodhouse and Rawson Electric Supply Company write to inform us that they have introduced an inexpensive, but artistic, table lamp. This is designed to meet the requirements of those who wish to use incandescent electric lamps for studies, lecture tables, &c., or for exhibiting and explaining the nature of the electric light without having to incur the expense attached to ordinary installations. They are made in three different styles, either polished or nickelled, brass and green bronze. A neatly designed switch is placed in a position similar to that occupied by the regulator of an oil lamp. Two terminals are placed in the base of the lamp, so that the connections, which can be readily made, are not obtrusive.

ROYAL INSTITUTION.—At the general monthly meeting of the members held on Monday last, Mr. Warren de la Rue, D.C.L, F.R.S., vice-president, in the chair, Sir U. Kay-Shuttleworth, Bart., M.P.; Sir W. Thomson, F.R.S.; Dr. John Abercrombie, Messrs. W. H. Barlow, A. Carpmael, H. Doetsch, J. P. Fearfield, R. Gent-Davis, M.P.; J. Hopkinson, F.R.S.; J. Inglis, G. Palmer, S. P. Thompson, and W. Tomlinson, Major E. Cecil Johnson, Mrs. T. C. Leitch, and Mrs. S. S. Joshua, were elected members, and seven candidates for membership were proposed for election. The following alteration in the lecture arrangements was also announced:—Prof. Dewar, F.R.S., four lectures on Electro-Chemistry, in place of Prof. Tyndall, F.R.S., on Light.

Digitized by Google

ELECTRIC LIGHTING.—In the House of Lords on Tuesday night a Bill to amend the Electric Lighting Act was introduced by Lord Rayleigh, and read a first time.—In the House of Commons on the same night, in reply to Mr. Northcote, Mr. Mundella said:—"I am not prepared at this moment to state exactly what course will be taken with the one Bill and two provisional orders which this session seek authority, among other things, to amend the Electric Lighting Act, 1882. I may say, however, that the Government could not permit any amendment of the general law to be effected by means of a private Bill or a provisional order. The whole question is under the consideration of the Government, and will, if possible, be dealt with during the present session."

THE TELEGRAPH AT SCOTLAND-YARD.—In an article on Scotland-yard the *Daily News* says:—In addition to the communications regularly kept up by documents and printed sheets passing to and fro between each superintendent's office and Scotland-yard, the telegraph of course plays an important part in the keeping of all corners of the great system in touch with each other. Every policeman who rises above the rank of a constable is required to become a practical telegraphist, able to communicate through the Wheatstone instrument with Scotland-yard—where there is quite a considerable telegraph office—from any divisional or subdivisional station. Either by the telegraph or by telephone this executive department of Scotland-yard is also in communication with all the principal public buildings and establishments throughout London.

THE USE OF THE TELEPHONE.—At a recent meeting of the Manchester Board of Guardians, information was telephoned from the workhouse that the labourers on the farm were marching in a body, 150 strong, to the guardians' meeting. Police were summoned by telephone from the Town Hall, and when the labourers arrived the authorities were fully prepared for any demonstration. The Board sent out the workhouse governor with an offer to receive a deputation if the others would go away, and this was agreed to. The deputation asked that the men who were in receipt of relief should not be required to be at the farm until ten in the morning, so that they might have an opportunity of looking for employment. This arrangement the Board assented to, and the deputation having rejoined their colleagues and reported the result, the demonstration terminated peaceably.

NEW COMPANY.—The Railway Electric Lighting Company has been formed to acquire and develop the patents and business of the Railway Electrical Contractors, for lighting railway carriages by electricity generated by the momentum of the train, and stored in accumulators. The capital is £130,000, in shares of £5 each, of which 20,000 shares are now offered to the public. Patents have been secured for France, Belgium, Italy, Germany, Austria-Hungary, and the United States. The directorate is a strong one. We should be pleased, however, to be clearer upon the particular manner in which it is proposed to utilise the *momentum* of the train; and it suggests itself to us that as a matter of possibility *motion*, and not momentum, is utilised, and if this is so, it becomes a question as to whether there are not other patents which may claim priority on the face of the prospectus before us.

INTERIOR ARC LIGHTING.—At a concert given by the Blackheath Conservatoire of Music, at the Rink Hall, Blackheath, on the 23rd ult., the room was brilliantly illuminated by two Brockie-Pell arc lamps, which ran without a flicker for four and a-half hours, and gave the utmost satisfaction. The lamps, which were connected up in parallel, were fed by a current of 22 amperes, from a Holmes-Burke battery of 56 cells of the ordinary size, and the same battery, without being recharged, was again used on the following day for four hours at the new Art Club, Blackheath, to supply a current to the above-named lamps at a private concert. We are informed that at a recent trial before an eminent electrical authority, 40 of these cells ran a Brockie-Pell lamp of 2,000 c.-p., taking 12 amperes, for seventeen and a-half hours continuously with a single charge. We believe this to be by far the best result as yet obtained in electric lighting by any primary battery.

EARTHQUAKES.—A report comes from St. John, Antigua, to the effect that on January 20th, several shocks of earthquake were felt. The first at 1:20 lasted a longer time than any, and was sharp, but those at 1:40 and 5:55 were slight. The one at 5:15 was much stronger. It was thought they came from the south-east and travelled to the north-west. On New Year's Eve an earthquake was felt in the central parts of Norway, particularly at Elverum and Löiten, where the houses shook. Another shock was felt in the province of Christiansand, at about 4 a.m. on January 16, followed by vivid flashes of lightning. In several houses the doors sprang open, and furniture, &c., was moved. A girl was thrown out of bed in one place. The barometer was very low at the time, but remained the same as on the previous day.—A slight shock of earthquake was felt at Moorshedabad on the afternoon of February 1st, at 3:20. A simultaneous shock was felt in Calcutta.

THE PATENT OFFICE.—In consequence of the change of Government it has become necessary to consider what steps ought to be taken with regard to the Departmental Committee which was appointed by the late President of the Board of Trade, Mr. Stanhope, to inquire into the present constitution and working of the Patent Office. The committee consisted originally of three members, viz.:—Baron H. D. Worms, M.P. (the then Secretary to the Board of Trade), Sir Farrar Herschell (the now Lord Chancellor), and Lord Crawford and Balcarres, and it has been decided that the most expedient course will now be for the Lord Chancellor, in conjunction with the present President of the Board of Trade, to appoint a new committee. They have accordingly appointed a new committee, which will be presided over by the Lord Chancellor as chairman, and will consist of the following members:—The Lord Chancellor, Lord Crawford and Balcarres, Baron H. de Worms, M.P., Sir B. Samulson, Bart, M.P., Sir R. E. Webster, Q.C., M.P., and Mr. C. T. D. Acland, M.P.

THE ELECTRIC LIGHT FOR HOSPITALS.—At the last meeting of the St. Saviour's Board of Guardians a report was received from the Building Committee stating that, after carefully considering the tabulated statement of tenders that had been received for lighting the infirmary at Champion-hill with electric light, and conferring with Mr. Jarvis, the architect, on the probable cost of lighting that establishment with gas, resolved that the tenders for electric lighting be no further considered, and recommended that Messrs. Jarvis and Son should be instructed to prepare specifications and drawings for the laying down and fixing of all the appliances and fittings required for lighting the new infirmary with gas. The Chairman said the majority of the committee were of opinion that they should have gas to begin with. If in the course of a few years the electric light was perfected it might be introduced with perhaps good effect. Mr. Cooksey maintained that the the electric light was an unqualified success, and urged its use on sanitary grounds. After some discussion the report was adopted.

THE TELEGRAPH CABLE AS AN ANTI-MONOPOLIST.—It may not be generally known that the telegraph cables laid in foreign waters and along foreign coasts have brought about in many cases an extraordinary change in the trade of the

Digitized by Google

localities at which they touch. On the South East African Coast, for instance, a few years ago, one or two mercantile houses held absolute sway, monopolising the whole, or nearly the whole, of the trade; for other and smaller people, Banyans principally, were unable to keep touch of the markets, or to buy on a sufficiently large scale for speculative purposes. But when steamers began to run and cables were laid these gentry began to find out that by the expenditure of a trifling sum they could obtain quotations and forward their orders by telegraph. By watching the local markets carefully and taking advantage of favourable opportunities they competed with and defeated the monopolists. The drastic measures frequently resorted to by local officials, whose interests were dependent upon the continuance of the monopoly, were no longer possible, for Lisbon was within reach, and justice could be obtained within an appreciable time. In the old days delays were endless and remedy practically unattainable.

SCIENCE AND DEMOCRACY.—It is with fee lings of gratification, not unmingled with dismay, that we find our estimate of Sir Henry Sumner Maine's forebodings relating to the future of Science under Democratic institutions, discussed in our leading article of February 19th, entirely borne out by his rejoinder to Mr. Godkin in this month's *Nineteenth Century.* Sir Henry singles out the passage we ourselves had quoted from the American's reply, with the remark that the admissions are "so candid as to leave me in doubt whether the writer seriously dissents from the argument which at first sight he appears to be criticising;" and sums up Mr. Godkin's case as follows: "The gist of all this may fairly be said to be that the American people refuse all submission to intellectual authority, unless it either is, or is seconded by, the authority of persons who have made a fortune in business." After what Mr. Godkin tells us of the relations of science to the multitude in the United States, Sir Henry Maine concludes with a prediction which bodes ill for the future of science: "For the honour of human nature there is one reason why this method of bringing over a sovereign multitude to a scientific opinion will never succeed. The combination of lying, cowardice and hypocrisy which the process of persuasion involves is utterly inconsistent with the possession of the highest intellectual faculties."

HINTS FOR SCOTLAND-YARD.—Mr. Wilfrid King, secretary of the Exchange Telegraph Company, writes to the *St. James's Gazette* as follows:—"Sir: Referring to the articles under the above heading in your issue of Saturday last, I venture to point out that the system of street fire and police signals recommended therein was introduced into this country in 1872 by the Exchange Telegraph Company, and was duly submitted to the fire and police departments. It was adopted by the Metropolitan Board of Works, for the Metropolitan Fire Brigade, in 1877; and has since been of the greatest service in telegraphing calls to fires. It was declined by the Police Commissioners, although we offered to supply signalling post and apparatus at all the 'fixed points' at cost price plus a nominal royalty. The system, with the latest improvements of the company, is neither costly to establish nor maintain; it is not unsightly, and does not require experts to work it. In the case of the Fire Brigade, the lines were erected and are maintained by the Postal Telegraph Department, and the same might be done for the police, so that underground wires may be available. Had this system been so used by the police on the 8th ult. a 'call' from a signalling-post in Pall-mall, when the first window was broken, would have stopped further damage, and have thus covered the cost of the entire system to the State."

THE ELECTRIC LIGHT AND THE DALTON LOCAL BOARD.—At the last monthly meeting of this Board the Clerk reported, on behalf of the Electric Lighting Committee, that in accordance with the Board's resolution, Messrs. Menzies and Co. had been requested to state the grounds upon which they valued the second hand engine and boiler specified by their tender at £300, and read Messrs. Menzies' reply thereto, with details of estimate showing the amount specified. Numerous other letters, received since the last meeting of the committee from engineers and also from firms in relation to the supply of plant for electric lighting purposes, were read. Resolved that the Clerk request Messrs. Menzies' engineer (Mr. McWhirter) to furnish the date upon which he made, as stated by him, an inspection of the engine and boiler specified in the original tender, and to state if more than one inspection was so made. Read letter of 13th February from the Board of Trade stating that it would be necessary before depositing patterns that the Local Board should state the system of lighting proposed to be adopted:—(*a*) For incandescent lighting; (*b*) for arc lighting. Specifying full details as to efficiency in, and safety of supply. Read letter of 13th February from the Local Government Board, stating that a local inquiry would be held upon the Board's application for sanction to loan.—The report was, after a long discussion, adopted.

STEAM POWER FOR ELECTRIC LIGHTING AT THE COLONIAL AND INDIAN EXHIBITION.—Messrs. Davey, Paxman, and Co., engineers, Colchester, who supplied the whole of the steam power for driving the electric light machinery at the last three exhibitions at Kensington, have been retained for the same purpose for the whole of the indoor lighting at the approaching Colonial and Indian Exhibition. The steam power required amounts to 1,200 indicated horse-power, and will be supplied by nine sets of engines, comprising six types, namely, one compound semi-fixed engine, whose boiler has 670 square feet of heating surface, and working at a pressure of 120lb. per square inch; two sets of compound horizontal engines, three sets of vertical compound high-speed engines, all of different sizes; one compound horizontal girder engine, two pairs horizontal simple engines. The steam will be supplied to the semi-fixed engine by its own boiler, while that for the other eight will be generated in five boilers, at 120lb. pressure for the compound engines, and in six boilers at 90lb. pressure for the simple types, twelve boilers in all. Although 1,200 is the power estimated for, the engines and boilers supplied will, without any difficulty, give considerably more than this. As the firm supplying them have had such extensive experience in exhibition lighting, there is every reason to feel confident that the eminent success of their machinery at the last three exhibitions will characterise it this summer. We hope to give illustrations of the above next week.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.—At the first annual meeting of this Association, held recently at Baltimore, the President, during the course of his address, said the greatest problem that can now occupy the mind of the electrician is the generation of electricity directly by decomposition of the hydrocarbons, &c., without the intervention of the dynamo. The solution of this problem will simplify the production at the coal fields, &c., and the discovery will reward the one who makes it with untold wealth and honour. There is an immense field for activity in perfecting and applying thermopiles, accumulators, potential transformers, Geissler tubes, incandescent lamps, arc lamps, semi-incandescent lamps, meters, gas engines, &c., to electric light purposes. The engineer who applies himself to these subjects has a

Digitized by Google

mine of wealth before him. Let him remember that electric lighting as a business did not exist ten years ago, and let him also recollect that the gas lighting is the largest manufacturing industry in the world, and that electric light will be welcomed in every place wherever gas has poisoned and blinded with its fume and flicker. At the close of the address, which was very cordially received, Dr. Moses made a few statements of a historical nature as to the fact that Pacinotti made his first machine as a motor, when the idea flashed across his mind that he would make it a generator—as shown by the attachment of a pulley and axles. It was strange that Pacinotti, with his thorough grasp of principles, as exhibited in the dynamo, had not arrived at the idea of its reversibility.

The Edinburgh International Exhibition.—One of the features of this exhibition will be a display of different systems of electric lighting. No fewer than 27 dynamos will be required to produce the necessary current, and these will be driven by 10 engines of the highest class, indicating 900 horse-power. Mr. Richard Millar, Glasgow, who is agent for Messrs. Thomson, Houston, and Company, holds the contract for lighting the permanent buildings, as well as the main entrance to the exhibition. The former are to be illuminated by 52 arc lamps, which should be amply sufficient to throw light into every corner. Down the central corridor of the temporary buildings, Messrs. King, Brown, and Co. are fitting up 1,444 lamps, which we believe to be the largest installation of electric lighting by means of incandescent lamps carried out by any company in the kingdom. To give an idea of the illumination of this portion of the exhibition, comparison may be made with the middle court at the Inventions Exhibition last year. In Edinburgh the court is 750ft. long, and with its 1,444 lamps, it will have one candle-power for every square foot flooring. The lamps are being fixed on the spearheads of the semi-circular roof. The centre spearhead carries three lamps, while the four on either side carry two. The whole system will be controlled from a massive coupling switch, by means of which the lamps will be instantaneously lighted or extinguished. Nearly all the wires have already been fitted up, so that there is no doubt that with ordinary care the installation will be completed in good time. The quaint buildings comprising "Old Edinburgh" are also to be lighted with incandescent lamps. This work has been entrusted to the Anglo-American Brush Light Company, who are preparing to fit in the wires for 250 lamps.

New South Wales.—Mr. J. Farnell, telegraph construction overseer at Tamworth, and son of Mr. J. S. Farnell, late Minister for Lands, has committed suicide. He bought a revolver, and went into the Coolabans Hotel. Soon afterwards a report was heard, and on a servant entering the room he found Mr. Farnell sitting on the floor against the sofa, with a five-chambered revolver by his side and a pool of blood on the carpet. A doctor was quickly in attendance, but found life extinct.—In regard to intercolonial cable messages, a contemporary says:—"It is not a little singular that, while the work which Mr. Burns set his hand to brought the Ministry to grief, the work which Mr. D. O'Connor, the Postmaster-General in the late Ministry, set himself to perform would have been of incalculable benefit to the traders and the press in the several colonies, as it was designed to cheapen the cost of intercolonial telegrams. It may be explained that the present subsidy of £7,500 a-year—of which New Zealand pays £5,000 and New South Wales £2,500—will expire in February next, and that the idea is to obtain a considerable reduction of rates in consideration of the continuance of the subsidy for a further term of five or ten years. Under the present tariff a message of ten words or under costs 7s., and every additional word 9d., no concession being made as regards press messages. It is to Mr. O'Connor's credit that, while in office, he succeeded in arranging —subject to the concurrence of the company's representatives at home, and of the New Zealand Government—that the tariff shall be as follows:—Ordinary messages, 6d. per word for every word contained in the message, no minimum charge being fixed; press messages, 3d. per word. The company was desirous of coupling the concession in regard to press messages with a stipulation that there should be a press guarantee of three times the number of words, but Mr. O'Connor did not see his way to agree to this stipulation. It is understood that the New Zealand Government strongly objects to continue the subsidy for more than the next five years, so that this objection may necessitate further communications with the directors in London."

City and Guilds of London Institute.—The following is the syllabus of a course of six lectures "On Some of the Industrial Applications of Electricity," by Prof. Ayrton, F.R.S., at the Central Institution, Exhibition-road, S.W., to be given from 5 p.m. to 6 p.m. on Friday afternoons, on the below-mentioned dates:—March 12th, "Electric Lighting": The lighting of houses, streets, trains, ships, lighthouses, and large areas with arc and incandescent lamps. Cost of electric lighting compared with that of gas or oil. Construction and regulation of arc lamps. Current potential difference, electromotive force, resistance and electric power. Mode of measuring electric power. Cost of a watt hour. Candle-power and efficiency of lamps. Mode of measuring. Life of incandescent lamps. Most economical potential difference to use with incandescent lamps. March 19th, "Electricity as a Motive Power": Construction and action of an electro-motor. Starting, stopping, and reversing. Power and efficiency of a motor. Mode of measuring. Effect of the speed on the power and efficiency. Action of an electro-motor compared with that of a dynamo. Governing of motors to run at constant speeds. Alternate current motors. Practical examples of machinery driven by electro-motors. March 26th, "Electric Storage of Energy": Accumulators, power, weight, and efficiency. Mode of measuring. Life of accumulators. Use of accumulators as regulators. Use as converters of electric power supplied with high potential difference and small current into power supplied with low potential difference and large current. April 2nd, "Electric Transmission of Power": Waste of power in the conductors. Advantages and disadvantages of the parallel system of supplying electric power. Economy effected by the use of the series, or the parallel series system. Most economical size of conductors. Heating of conductors. Uniform potential difference or uniform current along the mains. Use of accumulators, secondary generators, and motor-dynamos, in electric transmission of power. Utilisation of natural sources of power. Practical results already obtained with electric transmission. Comparison of electric with hydraulic and wire rope transmission of power. April 9th, "Electric Meters": Principles employed in constructing meters to measure current electromotive force, resistance, and power. Direct reading meters. Common faults in existing meters. Meters to record the total quantity of electricity, or the total amount of electric energy. Equitable modes of regulating the price of electric energy. April 16th, "Electric Locomotion": Tramcars carrying a store of electric energy. Electric launches. Methods of conveying electric power to moving vehicles. Electric, steam, horse, and wire-rope traction. Absolute blocking with electric railways. Telpherage. Probable future developments in the applications of electricity.

Digitized by Google

TELPHERAGE.*

BY PROFESSOR JOHN PERRY, F.R.S.

(Continued from page 308.)

In place of this hanger we may substitute a seat, of which a side view is seen in Fig. 18, and an end view in Fig. 19.

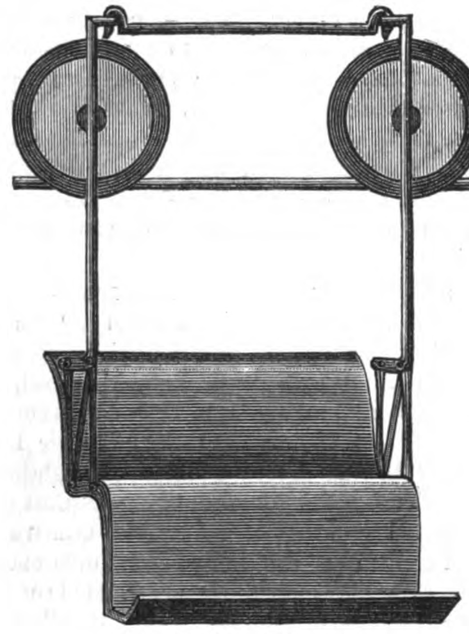

FIG. 18.—Seat (side view).

Two passengers can seat in it, and its weight is then nearly the same as that of each of the ten skeps when loaded, hence 20 passengers represent the load drawn by one locomotive. For passenger lines, however, it would probably be found more convenient to use a stiff rail rather than this flexible rod. Each skep weighs 101lbs., and when filled with clay its contents weigh about 250lbs. You will see that the hangers and buckets are insulated from the line, the cross-piece which connects the wheels being made of wood, so that the buckets may

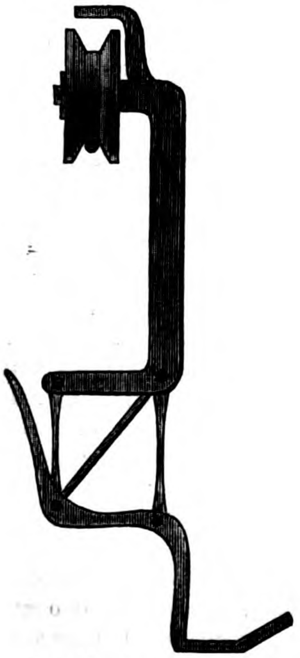

FIG. 19.—Seat (end view).

be handled without any shock being felt. Hence, should a dangerously high potential be used in working a telpher line, no danger need be feared from touching the buckets.

* Lecture delivered at the London Institution, 28th January.

This ingenious system of *single-wheeled skeps* (Fig. 20) we owe to the suggestion of Mr. Horace Darwin, of Cambridge, and the experiments of Mr. Gordon Wigan. A train of these single-wheeled skeps is now running before you in the model, and you will observe that while the friction has been greatly reduced, and the flexibility of the train increased so as to enable it to go more easily round curves, yet the practical handling of the skeps is as easily effected as the handling of the double-wheeled skeps. It is probable, therefore, that this is one of the improvements which we shall shortly introduce in telpherage. Mr. Wigan found that in the single-wheel skeps used at Weston there was a tendency for the wheels to alter continually in their distances apart, and that when a train was reversed in its motion it tended to buckle up, especially on curves. He found, however, that by putting the draw-bars, or rather the *draw-pins*, P, near the steel rod on which the skep wheel runs, the load in the bucket had an exceedingly great steadying action. His experiments were purely qualitative, and he contented himself by finding, from experiments made with the model train, a point of attachment for the draw-bars which gave good running. This point lies so close to the line that, owing to the necessary clearance in *underline* draw-bars, it was preferred to place them over the line and over the wheels. The problem, which is to be worked out by calculation and possibly by further experiments,

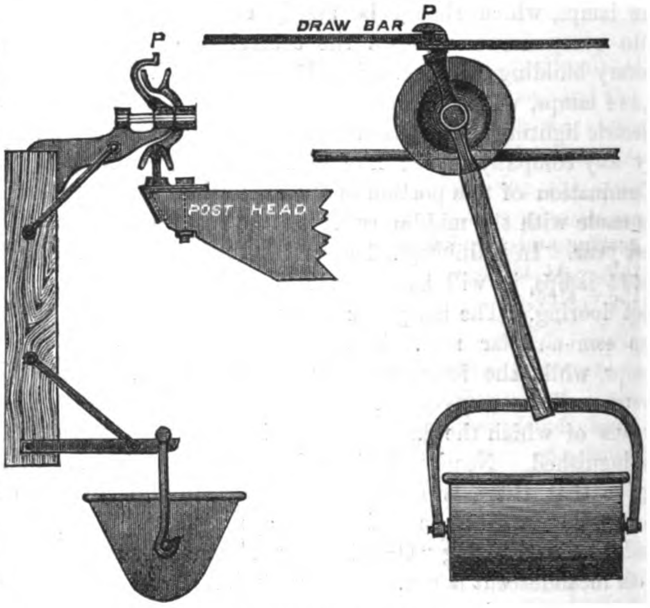

FIG. 20.—Single-wheeled Skep.

is to give the load such a leverage at the draw-pins as to prevent tilting and buckling, and yet not such a leverage as to prevent the swing of the load in the vertical plane under the line from acting as a *gravity buffer*, a matter much insisted on for all skeps by Prof. Fleeming Jenkin, and again well demonstrated by the experiments made for me by Mr. Wigan on traction in a line passing through the centres of the wheels, which mode of traction gives, of course, a practically rigid train. In this case the least obstruction on the line threw the train off, but when the draw-bars were placed so as to allow of a gravity buffer action, Mr. Wigan found that the model train would, on a straight part of the line, actually hop over a pencil rather than run off the line.

These single-wheeled skeps are very much cheaper than the the others, and they move with much less friction. Finding the one-wheeled skeps to run so well Mr. Wigan even suggested and tried a *one-wheeled locomotive*, and it, too, answered admirably on the model, so that we have every hope of producing a full-size cheap locomotive with only one wheel.

The "*Tandem Locomotive*," which is the type used at Glynde, is shown in Figs. 21 and 22, and a specimen of it is propelling one of the three trains in the model before you. This locomotive is very much simpler in character than the Telpher Locomotive shown in Fig. 3, and used with the Fitzroy street

Digitized by Google

model, Figs. 4 and 5, and also much simpler than the locomotives described by Prof. Jenkin in his lecture delivered to the Society of Arts in 1884. A vast amount of ingenuity has been expended by Prof. Jenkin and the staff of the company in elaborating methods by which the rod or rail might be gripped very tightly between the wheels of the locomotive, and for driving these wheels from the motor. In this slide which I now throw on the screen, you will see some of the forms whose description is the most important part of Prof. Jenkin's paper to which I have referred. We find, however, that with the present very simple form of locomotive, shown in Figs. 21 and 22, we can

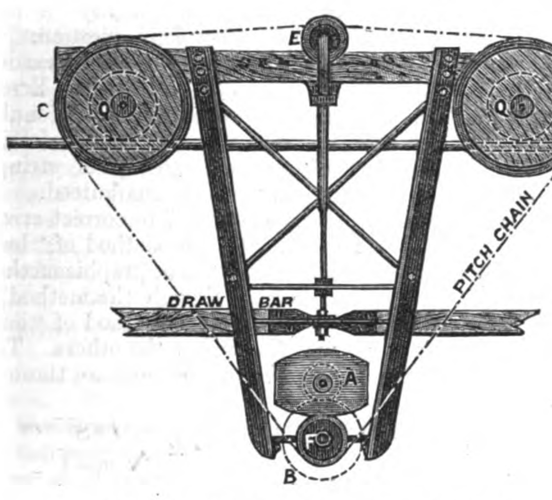

Fig. 21.—Tandem Locomotive (side view).

go quite readily up inclines which are as steep as 1 in 13, and we are therefore reserving the more elaborate forms of friction-gearing and grip-locomotives for such lines as are steeper than this. At Glynde, gradients have been introduced here and there, steeper than were absolutely necessary, and they enable us to see how readily a train may be drawn up an inclined part of the line.

Figs. 21 and 22 show that the frame of a locomotive now in use is made as light as possible consistently with stiffness and strength. It is suspended by two wheels Q (Figs. 9, 21 and 22), which have india rubber tyres fastened with cement to the iron underneath them, and which are also gripped at the sides. The speed of 1,600 or 1,700 revolutions

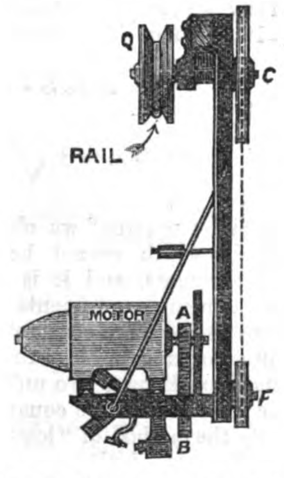

Fig. 22.—Tandem Locomotive (end view).

per minute of the motor is reduced by a pair of spur wheels at A and B to about five hundred, and on this second spindle there is a chain wheel F. (Fig. 22), so that a chain going round this wheel, and round two chain wheels at C, C, causes the two driving wheels of the locomotive to rotate. E is a little wheel which tightens the chain. Experience shows that the weight of the locomotive, which is not much greater than that of one of the loaded skeps, is sufficient, with these india rubber tyres, to produce a sufficient grip on the line for the propulsion of the train.

It is quite true that the pair of india rubber tyres will last only a fortnight in the wet season of the year; but we find that even on the wettest days the locomotive will perform its work quite well. In dry weather the life of the india rubber tyre is of course very much longer. Should the rod on which the train runs be kept quite dry, I have no doubt that this simple form of locomotive would be sufficient for as steep a gradient as even 1 in 10. We have only tried one plan for artifically drying the line, by scraping the line with a piece of india rubber carried in front of the locomotive. As, however, the locomotive performs its work quite well without any such artificial drying, we prefer to leave the line in its natural state. Of the three kinds of material which we have used to make the tyres of—metals, leather, and india rubber—the india rubber has been signally the best.

Some of you may be astonished to find that this small locomotive running on the model can exert a pull and push sufficiently great for the propulsion of trains on this flexible line. In the real telpher line, when the locomotive is climbing to a post, we are particularly struck with its propelling power, even when we are told that only one mechanical horse-power is required to be exerted by the locomotive. In fact, our eye deceives us, and we imagine that the propelling power on a flexible line like this, where the rods sag down very much when the trains pass over them, and become quite straight to the eye after the trains have passed, must be much greater than it would be on a rigid rod. But this is not the case, careful experiments having shown that the propelling power on such a flexible line when the train is made to cover one or two or more spans completely, and not any fraction of a span, is pretty much the same as on a stiff line, because there is always the same amount of weight descending on the flexible line as there is ascending to a posthead, so that the weight of one part of the train balances that of the remainder all the time.

The motor now in use at Glynde is of the Reckenzaun type. As the bad insulation of the motors in telpherage may be regarded as the only weak point of the whole system, we are directing attention now, with the help of Mr. Reckenzaun and Mr. Immisch, to obtaining the best form of moter, which can be left to work by itself for a long time without breaking down in insulation or requiring the adjustment of the brushes, and which shall, like the other moving parts in telpherage, require but very little attention in oiling. We find that unless motors, as they have hitherto been made, are closed up very much more completely than it is possible to cover them on a telpher locomotive the insulation is very likely to suffer in damp weather when a train is not running. Luckily, however, if a small current which is insufficient to work the line is maintained for a short time through the motors before the day's work commences, the evil effects may be got rid of. Each of the motors at Glynde receives a power of about 1,500 watts, or about two horse-power, and as the potential is about 200 volts everywhere on the line, each motor receives about 8 amperes when a train is running at about $4\frac{1}{2}$ miles per hour. We have not observed that the constant reversals of the current that occur as the locomotive passed over the post heads has produced any evil effect on the dynamo machine, which is a Crompton shunt machine of the Gramme type, capable of giving out steadily a current of 24 amperes at a potential of 200 volts.

The engine which drives our dynamo machine is of a simple agricultural type, and is at present regulated by what is known as a Willans governor; but this method of governing will probably in future give place either to a less costly and more efficient arrangement, such as that of compound winding of the dynamo which is now well known, or we shall use no governors at all, as the trains themselves are governed to run at the same speed up or down an incline. The governor on the engine is supposed to maintain the potential at the poles of the dynamo steadily at 200 volts, admitting more or less steam to the engine for this purpose, and at the part of the line most distant from the engine house we do not find that at Glynde there is a much greater falling off in

Digitized by Google

potential than from 10 to 12 volts, so that the loss in transmitting power to the farthest end of the line is not more than about one-tenth of a horse-power.

(To be continued.)

EFFICIENCY OF THE EDISON-HOPKINSON DYNAMO.

A number of gentlemen, at the invitation of Messrs. Mather and Platt, of the Salford Iron Works, Manchester, gathered together at the works of the firm on Saturday, February 27th, to witness some experiments with the Edison-Hopkinson dynamos. The immediate cause of these experiments was a suggestion of Dr. John Hopkinson, made during the discussion of Mr. G. Kapp's paper, read before the Institution of Civil Engineers, to the effect that measurements relating to the efficiency of dynamos were not nearly so accurate as they might be. When Faraday was asked to witness an experiment, he wished to know beforehand what he was expected "to see." The following paragraphs from a circular distributed to the visitors by Messrs. Mather and Platt will answer the question, "What went ye to see?":—"Up to the present time the method adopted for determining the efficiency of conversion from mechanical to electrical energy by dynamo machines has consisted in a direct measurement of the power transmitted to the dynamo through the driving belt by a transmission dynamometer, and the determination of the electrical power developed outside the machine. The latter portion of the experiment presents no difficulties, and even when large powers are dealt with a high degree of accuracy is easily attainable; but all who have used a transmission dynamometer know that it is exceedingly difficult to obtain accurate results, even when the utmost precautions are taken, and the difficulty is vastly increased when large powers have to be dealt with. If the power transmitted amounts to 50 horse-power or upwards, probably few experimenters would undertake to guarantee the accuracy of the observation within limits of even 2 or 3 per cent.; and the determination of the efficiency will be erroneous precisely in proportion to the error in the dynamometer. Probably, therefore, no efficiency experiments hitherto made on a large scale can be regarded as having any certainty of accuracy within at least 3 per cent."

As we have said, "Dr. John Hopkinson suggested an entirely new method by which the efficiency of conversion can be determined with great ease, and which is not open to the above objection. The method also throws light upon other points of great interest, and especially on the much-discussed question as to the relation between the dynamo when used as a generator and motor respectively.

"Let two dynamos, approximately equal in dimensions and power, have their shafts coupled by a suitable coupling, which may serve also as a driving pulley; and let the electrical connections between the dynamos be made so that the one drives the other as a motor. If the combination be driven by a belt passing over the coupling pulley, the power required to be transmitted by the belt is the waste in the two dynamos and the connections between them. Moreover, by suitably varying the magnetic field of one of the dynamos, the power passing internally between the two machines can be adjusted as desired. If, then, the electrical power given out by the generator is measured, and also the power transmitted by the belt, the efficiency of the combination can be at once determined. The beauty and advantage of the arrangement lies in the fact that the measurement, which presents experimental difficulties, is of a small quantity, viz., the power transmitted by the belt. Consequently, even a considerable error in the determination has but a small effect on the ultimate result. On the other hand, the measurement of the large quantity involved—viz., the electrical power passing between the two machines can, without difficulty, be made with great accuracy. Assume, for example, that the generator dynamo gives 50 horse-power, and the motor provides 40 horse power of this amount; then the driving belt has to supply 10 horse-power only, and an error of 3 per cent. in the measurement of this quantity would cause an error of only 0·6 per cent. in the final result. The method thus obviates entirely the objections to other methods formerly employed, and has, at the same time, the advantage that the actual mechanical power transmitted to the machines is small, and therefore more readily dealt with by the dynamometer. In fact, an error of ½ per cent. may be considered as the extreme limit, if ordinary precautions are taken."

Before stating the actual results of the experiments, it may be interesting to some of our younger readers, and those who have had little experience of "exact" work, to refer to some of the methods usually employed to eliminate errors. It is seldom that an experiment furnishes at once the information required, and generally more or less laborious calculations have to be made if any pretension to accuracy is in question. In reading from a scale, and especially in many electrical measurements, a mistake of one degree may easily be made. Errors of observation may be, and generally are, eliminated by multiplying observations. But, when we have to deal with defective apparatus, such as friction of pulleys, rigidity of strings, radiation, the absolute accuracy can never be guaranteed.

The three methods most usually employed to correct errors of observation are (1) the graphic, (2) the method of "least squares," and (3) the method of "means." The graphic method is coming more and more into vogue, though the method of "means" is by far the most general, while the method of "least squares" is perhaps not so well known as the others. The following formulæ, using the method of means, are those to obtain:—

Mean error of a single observation $= \pm \sqrt{\frac{S}{n-1}}$

Probable „ „ „ $= \pm \frac{2}{3}\sqrt{\frac{S}{n-1}}$

Mean error of result $= \pm \sqrt{\frac{S}{n(n-1)}}$

Probable „ „ $= \pm \frac{2}{3}\sqrt{\frac{S}{n(n-1)}}$

where S = the sum of the squares of the deviations of the result of each observation from the arithmetical means.

Take an example of some readings from an ammeter. Thus if $C = 119·5$, $C_1 = 119·7$, $C_2 = 119$, $C_3 = 120$; the most probable value of

$$C = \frac{119·5 + 119·7 + 119 + 120}{4} = 119·8$$

Then

$$(119·8 - 119·5)^2 = ·3^2 = ·09$$
$$(119·8 - 119·7)^2 = ·1^2 = ·01$$
$$(119·8 - 119·0)^2 = ·8^2 = ·64$$
$$(119·8 - 120·0)^2 = -·2^2 = ·04$$

Here S = ·78

and using the formula we get—

$$\text{Mean error of observation} = \pm \sqrt{\frac{·78}{3}} = \pm ·54$$

and so on.

In the method of "least squares" we obtain equations containing the magnitude which cannot be directly observed together with other constants, and it is necessary in using this method to make as many experiments as will furnish data for as many equations as there are constants to be determined. This, of course, is in accordance with ordinary algebraic work, where, as every schoolboy knows, two unknowns require two equations, and three unknowns three equations, in all his ordinary calculations. By the method of "least squares" a value is calculated such that the sum of the squares of the differences between it and the observed values has the smallest possible value. In the usage of the method of "least squares," a graphic method is frequently used for the interpretation of experimental results, from the study of which "interpolation formulæ" are deduced.

With the graphic method, a series of points are obtained the position of which is determined by ordinates and abscissæ. Usually the points obtained experimentally do not form any regular curve, but so that a curve may be drawn with half the ordinates of the points terminating on one side the curve and

Digitized by Google

half on the other, the curve showing where the points should come if no errors of observation intervened. To interpret some of these curves requires a knowledge of the calculus.

We have thus briefly referred to the difficulties in the way of exact measurements, and the methods usually employed in minimising the errors. Exactness, again, depends largely upon the simplicity of the operations and the values of the quantities to be measured. The measurements in a draper's shop, for example, are approximate only, and although it is not important to obtain great accuracy in measuring a yard of calico, the error in very large quantities may be appreciable and of importance.

Dr. Hopkinson's suggestion with regard to dynamos was, as we have seen, in the direction of simplicity and smaller quantities to be measured. In fact, he measures the small resultant instead of the whole of the forces. The most elementary school books tell us that the resultant of two forces is nil when the forces are equal and opposite, and that the resultant of two forces acting in the same or opposite directions is the algebraic sum of the forces. Thus, if they act in the same direction, the resultant will be the sum of the two; if they act in opposite directions, it will be the difference of the two, and while the forces may themselves be very large, this difference may be comparatively small, and the measurement of the difference will lead to a much smaller observational error than the measurement of the forces themselves. This elementary proposition embodies the suggestion of Dr. Hopkinson, who, as we have seen, couples the shafts of two approximately equal dynamos, and makes the connections so that the power required to drive the generator is partly returned by the power given out by the motor. If the two machines were absolutely equal in all respects, and the apparatus such that no loss of any kind took place, the power absorbed by the generator would be given out by the motor, and no work would be required from the engine. The experiment witnessed on Saturday may be thus briefly described. Power

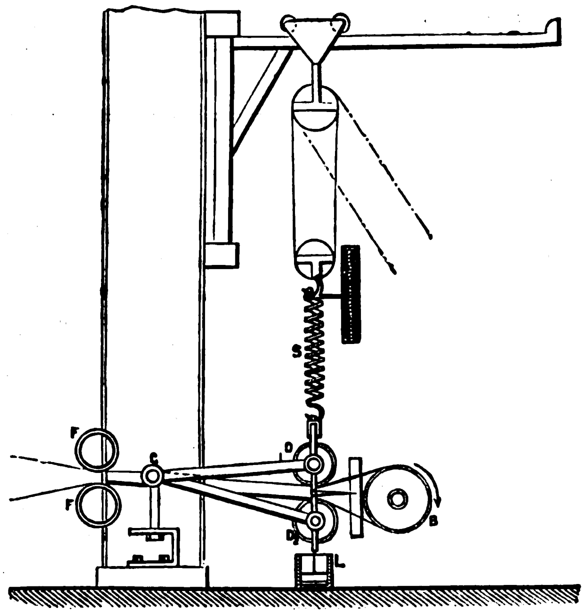

Fig. 1.

was obtained from an engine to drive a dynamo acting as a generator. The current thus obtained was used to actuate a motor, and the motor developed mechanical energy which was returned to, or, so to speak, assisted, the engine. When driving the generator alone the engine would be required to do certain work, but when the connections were made to the motor the amount of work required from the engine was greatly lessened.

The two machines experimented with were of the well-known Edison-Hopkinson type, with all the latest improvements introduced by Dr. John Hopkinson and Messrs. Mather and Platt. The dynamos are similar in all their dimensions and winding, and are each intended for a normal output of 110 volts, and 320 amperes, at a speed of 780 revolutions per minute. They are both shunt-wound only, and have solid wrought-iron magnet cores and field pieces. The commutators are of copper, insulated with mica, with 40 bars. The general arrangement of the dynamometer is shown in Fig 1. It is of the Hefner-Aleneck type. In the figure, B shows the driven coupling of the dynamos; D, D the guide pulleys of the dynamometer turning about the fulcrum C, and supported by springs, the tension of which is read by a pointer against a fixed scale, when the index of the dynamometer is brought to its fiducial mark. L is a dashpot, F F are guide pulleys, bringing the belt parallel with the dynamometer. The potential between the terminals of the generator was measured by a Thomson graded galvanometer, previously carefully standardised by a Clark cell, and the current by passing it through a known resistance; the difference of potential between the ends of the resistance being determined by Poggendorf's method by direct comparison with the Clark standard cell.

The resistance of the armatures and magnets of the two machines is as follows:—

Generator......	Armature............	0 009947	ohm.
	Magnets	16·93	„
Motor	Armature............	0·009947	„
	Magnets	16·44	„

During the experiments made with these machines a current of 521 amperes was passed through the two armatures in order to test their mechanical strength, this current being nearly double that for which the machines are designed. They were found to carry this current with perfect ease without any sparking at the brushes or displacement of the wires of the armature. Such a current maintained for any length of time would lead to undue heating of the armature, but the fact is of importance as showing that a momentary short-circuiting of the machine would not result in serious mechanical damage to the armature, and especially that, when the machines are used for transmission of power, for a short time they are capable of giving about double the output required of them for regular working. In connection with locomotive power this is a matter of considerable importance, as frequently on a short incline or in starting the cars a far greater tractive force is required than during normal working.

The dynamos above described and tested, it may be mentioned, are intended for the new tobacco manufactory of Messrs. W. D. and H. O. Wills, of Bristol.

We had hoped to have ready a perspective view of the dynamos and dynamometer as arranged for the experiments, but some delay occurred, and the photographs were not ready in time to be engraved for this issue, so that we shall defer the results of the actual experiments to next week, merely saying that the figures obtained showed an efficiency of 90 per cent.

(To be continued.)

Electricity and Mining.—A few days ago a party of gentlemen interested in mines assembled at the Granville Deep Pit, Upper Hanley, to witness some experiments in blasting with a safety cartridge, of which Mr. Miles Settle claims to be the patentee. The patentee claims for his cartridge that, when exploded, the flame is so protected, and after the act of explosion extinguished, that it does not communicate with the outer air, and that therefore, in the presence of inflammable gas, it is absolutely safe. The cartridge, which has often been described, is 18in. long, and contains dynamite or tonite floating in water, enclosed in an oilskin bag. One cartridge was carefully placed in each hole, and a tamping of soft clay put next. After that the holes were stemmed and rammed in the usual way, the electric wire being left in in contact with the percussion at the head of each cartridge. The party then retired a distance of ten yards to the battery, and all lights were removed. The whole was fired simultaneously, and brought away about fifty tons of coal. In this seam the face comes away with very little dust, and on this occasion there was almost none. In the absolute darkness no flame from the electric spark or the explosion of the dynamite was visible, and the result of the experiment was pronounced to be entirely satisfactory.

ELECTRIC DISTRIBUTION.

The Electric Lighting Companies whose business prospects were discussed in our last week's leader have other reasons for congratulation beyond those dwelt upon in their several Reports. Any of the shareholders who were present at the meeting of the Society of Arts on the 17th ult., when Prof. FORBES read a paper on some points in Electrical Distribution, will understand what we mean when we say that the legal and the financial obstacles to the progress of the new illuminant have not been the only or chief causes of failure. It is true that the hindrances just specified have been great, and in any case might have proved insurmountable. Prof. FORBES dwelt with sufficient emphasis upon these, giving it as his opinion that no sane man will invest his money in speculations hampered by the conditions imposed under the Electric Lighting Act of 1882; and he added something to the stock of argument against that measure by pointing out the very questionable conduct of statesmen who, while professing to guard against the creation of fresh monopolies, enacted a measure which was certain to leave the old monopolies in undisputed possession. "If (said he) the gas monopoly was truly so very irksome, the encouragement of a rival illuminant would have been the best cure for the evil; whereas our legislators acted as if they were parties interested in maintaining the gas monopoly, for they imposed such restrictions as rendered it impossible for electricity to be supplied to the general public;" and he urged, as we ourselves have repeatedly done, that electricity should be allowed to compete with gas under precisely similar disabilities and with equal advantages. "This is not doubling a monopoly; it is splitting it into two, and destroying the monopoly by admitting open competition." As to the financial difficulties which have beset the undertakings from the very beginning, they are hit off to a nicety in his reply to American critics who have questioned the soundness of Prof. FORBES' scientific calculations, because they do not confirm the extravagant promises of Company prospectus mongers. Singling out a sample by way of illustration, and examining it under the light of ascertained facts, he significantly observed that "this manipulation of figures may suit American financiers, but it is *not* electrical engineering."

With equal candour, however, the lecturer admitted that there had been faults on the part of the profession just named. Electrical engineers had not conducted the work with which they had been charged as carefully and conscientiously as they ought; and they had especially erred in grudging the necessary amount of forethought and calculation in preliminary arrangements, so as to secure the best results by the most economical means—a want of caution the more reprehensible seeing that existing data were imperfect and the whole business novel. It is in these respects that promoters may now find grounds for encouragement in the clear and concise account of the rapid progress scientific workers have made in supplying trustworthy bases for future operations, as well as in the marked improvements rendered available by practical experimenters. In respect to the former very little need be said. It is hardly an exaggeration to say that the whole energy of the scientific world has latterly been concentrated upon the phenomena of electricity; and it is certain that our exact knowledge of this subject has increased beyond all precedent under the impulse which a promising industry has created. As to practical inventions, they have more than kept pace with theoretical speculation. It is difficult to separate the two, and it is perhaps useless to attempt it; but, to name only a few improvements which are likely to stand the test of practice, there is the important step recently taken to regulate the glow lamp by altering the length of the filament; then there is the improved shunt, which promises to relieve us of the inconvenience of a breakage by introducing a resistance not too great to seriously affect the ordinary circuit. The construction of the lamps are vastly superior to what they were even a year ago, and the same may be asserted of dynamos all round. The automatic cut-out, and the electric current meter are also now in a condition to satisfy the requirements of any electric lighting Act, or the stringent regulations of insurance companies. Altogether, we agree with Prof. FORBES that the facilities now at the disposal of the engineer for designing satisfactory schemes of electric lighting, and which have been added to his store during the past year, are very abundant.

Improvements in secondary batteries which promise to become an almost indispensable factor in every electric light installation of the future have been not less numerous and important. Indeed, it was to the consideration of these adjuncts to the electric generator that the lecturer devoted a great part of his discourse on the distribution of electricity. The economical advantage of employing secondary batteries is obvious, notwithstanding the first loss of energy; but until recently the attempts to employ them in dis-

tributing stored electrical energy over wide areas have wholly or partially failed, for want of an indicator, to inform us of the condition of the cells, and because the personal inspection of an attendant was constantly necessary. These storage cells are now constructed so as to last for a considerable period. But what is wanted more particularly is that they should take current from the dynamo only when they require it. Something is required in the nature of a switch to act with the state of charge. Fortunately more than one device is now on trial which promise a satisfactory solution of the difficulty; and even without it there are many installations on such a scale as would warrant the employment of attendants to examine the condition of the cells at frequent intervals. Practical experience has demonstrated the useful fact that secondary batteries can be employed with economical advantage in large districts, while in small areas a direct service is the cheapest.

Of the new form of appliance called transformers, patented by Messrs. GAULARD and GIBBS, although we cannot speak of it with such positiveness, we are disposed to regard it with even greater hopefulness. By one of those common, but none the less strange, coincidences M. GAULARD has devised by actual experiment a remarkably perfect secondary generator on principles the true nature of which were being simultaneously elucidated through the insight and dexterity of Prof. HUGHES. It is in reality an induction coil; but constructed on lines which the induction balance has shown to be theoretically perfect. The loss of energy in charging it is quite inconsiderable; and if its serviceableness in other respects answers to the predictions of its friends, there will be no objection to it on the score of waste. The bearing of these inventions on the problem of electrical distribution will be seen if we quote a sentence from Prof. FORBES' lecture, "Suppose we use 10,000 volts, we may have 100 generators in series, each using 100 volts, or we may make any other arrangement. If it were done as I say, then a wire of one square inch section will carry current enough for 100,000 lamps, each consuming 60 watts." Moreover, any desired variation in the circuits could be attained with the greatest facility; and, according to M. GAULARD, if the leads in this arrangement consist of two parallel wires, and currents in opposite directions are sent through, not only no induction on the external circuit will appear, but no self-induction on the two leads can arise.

CORRESPONDENCE.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is not my custom to reply to reviews of any of my works, but the writer of the friendly notice of my "Dynamo-electric Machinery" in your last issue has fallen into two mistakes which concern not so much my work as the general scientific questions involved. As he is not alone in his misapprehension, I think it may be well for me to send you a brief correction of the points.

First, he says (p. 309) "It would also be well to finally abandon the figure 746 as representing the number of watts corresponding to 1 horse-power. We know from Lord Rayleigh's determination of the ohm and of the volt that the exact figure, neglecting fractions, should be 736, and think it high time that the correction should be made in all new books." Now, whatever Lord Rayleigh may or may not have done, his work has not altered the definition either of the horse-power, the watt, the ampere, the ohm, or the volt. All he has done has been to show that the B.A. unit of resistance was less than one ohm, and that the B.A. unit of E.M.F. was less than one volt. The watt is *not* the product of one ampere into one B.A. unit of E.M.F.: a watt is *not* equal to the rate of expenditure of energy when one ampere flows through one B.A. unit of resistance. The watt has been settled once and for all as the product of one ampere into one volt, and is therefore equal to ten million ergs per second. No other definition has ever been even suggested. The horse-power is defined as equal to 33,000 foot-pounds per minute (at London). No alteration in this value has been suggested by Lord Rayleigh, or in consequence of his work. These being the definitions, there can be no question as to the essential correctness of the figure 746. I give the calculation in full:—

1 volt $= 10^8$ absolute units of E.M.F. (C.G.S. system)
1 ampere $= 10^{-1}$ " " of current (" ")
1 watt $= 1$ volt-ampere $= 10^7$ ergs per second
1 H.-P. $= 33{,}000$ foot-pounds per minute (at London)
$= 550$ foot-pounds per second (at London).

So far, these are definitions about which there can be no dispute.

1 foot $= 30{\cdot}4797$ centimetres
1 pound $= 453{\cdot}59$ gramme
gravity $= 981$ "centims-per second-per second" (at London)
Hence, weight of 1 pound (at London) $= 453{\cdot}59 \times 981$ dynes
" " " $= 444972$ "
Whence
1 foot-pound (at London) $= 444972 \times 30{\cdot}4797$ ergs
" " $= 13{,}562{,}601$ "

Therefore,

$$1 \text{ horse-power} = 550 \frac{\text{foot-pounds}}{\text{sec.}} = 550 \times 13562601 \frac{\text{ergs}}{\text{sec}}$$

$$1 \text{ horse-power} = 7{,}459{,}440{,}000 \frac{\text{ergs}}{\text{sec}}$$

$$1 \text{ horse-power} = 745{\cdot}944 \times 10^7 \frac{\text{ergs}}{\text{sec}}$$

whence, finally,

1 horse-power $= 745{\cdot}944$ watts.

If the writer of your notice had said that one horse-power was equal to 736 of the products (not watts) of amperes into B.A. units of E.M.F. (not volts), I should still object; for if he uses units that are smaller than the true ones his reputed watts will be too many, and to bring them to horse-power he ought to divide not by 746, nor by 736, but by 756 or some greater number. For my own part, I do not use B.A. units of E.M.F., nor B.A. units of resistance, nowadays; nor do I call them volts and ohms when I know that they are not such, but are less than the volt and the ohm respectively. As a plain man who calls a volt a volt and an ohm an ohm, I write, and shall continue to write, 746 watts equal to one horse-power.

The other point in which I wish to offer a correction to your notice is the statement of the writer that "a motor has no critical speed." He must pardon me if I venture to say that he is not aware of the proper use of the term "critical speed" in relation to self-regulating dynamos and motors. He uses the term "critical speed" in the sense of that speed below which the dynamo refuses to excite itself. Of course, if he wishes to make that definition he is entirely welcome, only it is not the sense in which the term has been used by me, or, before me, by other writers on dynamos, notably Profs. Ayrton and Perry. If the sense in which the writer of your notice uses the term were correct, then no magneto-machine or separately excited dynamos could have a critical speed. As I and those before me have used the term it has been used to signify that speed at which the characteristic curve of the machine runs approximately parallel to the line that represents (by the tangent of its slope) the armature-resistance. And in this sense every motor has a critical speed, utterly independent of the question whether its field-magnets are excited by the same current that runs through its armature, or whether they are excited in any other way.—Yours, &c.,

SILVANUS P. THOMPSON.

CABLE-LAYING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of Feb. 26, page 301, you ask how is it that considerable errors are often found in the position of cables laid close in shore, where, it might be supposed, no difficulty should exist in plotting those positions accurately.

Cable engineers constantly find a certain amount of incorrectness in the details of all existing charts, and for the work which your paragraph refers to not even the charts of the English Channel should be trusted too implicitly.

During the surveys effected for the construction of charts the points used for cross bearings or triangulation are frequently carelessly sketched in; it consequently happens that the same points are not taken by different observers. In order to obviate this error, to a certain extent, it is usual in plotting a coast cable to mark on the charts the points used in the original observations, and to sketch in the salient or most remarkable features of the coast with their respective bearings and angles.

As will be easily understood, the error of plotted position due to incorrectness in the chart diminishes as the distance from the shore increases, but when close in shore a very careful selection of the points to be used in plotting the position of the cable is absolutely necessary.

It is well that *The Electrician* has drawn attention to this question, as many men new to cable work must often have been puzzled at the discrepancy between their results and those obtained by other observers.

The choice of points on shore demands a certain amount of experience, for not only must the most salient spots be quickly chosen, but those positions must be selected which are likely to be accurately laid down on existing charts. This very important branch of the work should be carefully studied by young cable engineers, and in order to be accurate in their observations, they must remember that the relative positions of all points on an admiralty sheet are not laid down with mathematical precision. Indeed, so much is this the case, that it is frequently necessary to construct a special chart for the work in hand, or at all events to correct the existing surveys.—Yours, &c., W.

THE MONOPOLY IN TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have spoken to a considerable number of gentlemen, of many nationalities, interested in the telephone, *but outside the monopoly*, as to the advisability of holding a conference in London or Paris to discuss the telephone in general, investigate claims, and consider what steps, if any, it will be advisable to take to protect the public and the electrical profession against the present monopoly, and all agree that such a conference is most desirable, and have promised to give the scheme all the support and assistance in their power. As it is impossible to see every one personally or communicate, I shall be glad to receive a line from all who are willing to assist with advice or information, or who would be desirous of attending the conference, admission to which will be by ticket only.

Any suggestions will be thankfully received.—Yours, &c.,

W. E. IRISH.

Rosemont Lodge, Richmond, Surrey, March 1, 1886.

RESISTANCE AS VELOCITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: No one has ventured to rebuke Mr. Swinburne for his very flippant treatment of this serious subject in your issue of Feb. 19th. Is this because no one really believes that "resistance is of the nature of velocity?" Yet, I quite recently heard a distinguished physicist use those identical words! The process by which resistance is converted into velocity reminds one of the small boy, who, having a complicated rule-of-three problem given him, calmly proceeded to reduce acres to pence, with deplorable results (from his point of view). The next time Mr. Swinburne feels his common sense outraged, let him contemplate the change-ratio for resistance expressed in electrostatic units—viz., $R = [T L^{-1}]$; what does that mean? The right hand side does not look like velocity. Shade of Maxwell! Can it be that resistance is occasionally of the nature of *slowness?*—Yours, &c. SYDNEY EVERSHED.

Kenley, Surrey.

ELECTRO-CHEMICAL EQUIVALENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your issue of the 26th ult. contains a review of Prof. Silvanus Thompson's "Dynamo Electric Machinery," and in it you call attention to the data respecting the electro-deposition of copper. I may, perhaps, therefore, be allowed to call Prof. Thompson's attention, through the medium of your columns, to the discrepancy between the electro-chemical equivalents as published in his "Elementary Lessons in Electricity and Magnetism" (*a*), and the data contained in his "Dynamo-Electric Machinery" (*b*).

Grammes per Ampere Hour.

	Copper.	Silver.	Gold.	Nickel.
(*a*)	1·1905	4·0824	2·4732	1·1124
(*b*)	1·1739	4·0250	2·4410	1·0990

The two sets of figures have evidently been calculated from different data. In the "Lessons" the datum appears to be that if the electro-chemical equivalent of hydrogen taken as ·0000105 gramme per coulomb; and if the other figures have been calculated from more recent or more reliable experiments, we shall have to alter our values for all the other metals.

If Prof. Thompson will kindly explain this he will doubtless confer a favour on others besides myself who are anxious to make use of the correct data.—Yours, &c., W. K.

INFORMATION WANTED.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you please inform me where hygrometers are for sale or made, such as Mr. Shoolbred spoke of in your number of Feb. 26? May I also trouble you to inform me what instrument is used for splitting the current of a series Gramme machine for the purpose of running two "Serrin" lamps? I have asked this question several times, but nobody seems willing to part with such knowledge. I was informed such an arrangement was often effected by the use of a coil, but the name of the coil was forgotten. May I also ask what is the regulation size wire to carry a current of 20 amperes the distance of four hundred yards?

Hoping you will pardon my stupidity, and that you will kindly assist me to gain this knowledge.—Yours, &c.,

London, W., February 27. A STRANGER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you or some able correspondent kindly give me some experiments with the telephone, as I am getting up a lecture on the same, and am at a loss for experiments.

A reply through your columns or the post will be esteemed. —Yours, &c., GRAHAM CAMP.

William-street, Norwich, March 3rd, 1886.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sorely puzzled, and should feel very thankful if you or any of your readers will kindly give me an answer to the following question:—

Is there any telephone line of 100 miles or more in length being worked regularly and satisfactorily in the United Kingdom or any other part of the world, and if so, where?

On pages 166, 186, and 265 of your Vol. XV. you have told us that very satisfactory *experiments* have been made in different places up to 200 miles, and I have frequently read of

Digitized by Google

speech being transmitted over what I believe to be impossible distances in America; but, if I heard correctly, Mr. Preece told us on Thursday evening last at the Society of Telegraph-Engineers and Electricians that it was not possible to work the telephone *in a practical manner* between London and Birmingham.

Surely over such a distance as this (113 miles) it is merely a question of *insulation*—a matter, by the way, which does not seem to receive so much attention as it deserves from some of our telephone companies.—Yours, &c., TELEPHONE.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "Horrors on horrors still accumulate" (Macbeth). There was one Electric Boy, and now there are two, operated apparently on rival systems. Let us hope this reduplication will spread to Electric Cows; then the three acres will be all that is needed to realise the working man's millennium. But, on the other hand, it would be a national calamity if it extended to Electric Bugs. I have felt it my duty to order a double supply of insect powder.—Yours, &c.,

W. H. STONE.

Oxford Villa, Geraldine-road, Wandsworth, S.W.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My note, p. 214, applied to "the Electric Boy" exhibited at the place mentioned on p. 131, and sufficiently answers Nos. 1 and 2 questions on p. 311. If Mr. J. does not understand, I can only say I thought he would have done so, though my letter was not addressed to him or intended to convince him.

He is entitled to no reply from me, however.

I did not say, nor did you, Mr. Editor, by the word "knew," intend to suggest that I possessed the name, address, or honour (?) of the personal acquaintance of either of the pennyshowmen in the sense Mr. J. seems to imply. His ingenious postscript, p. 311, however, throws a new light on the whole matter, for it is evident he understands my remarks did not apply to *the other boy*; and as it will please him best I leave him to place whatever construction he chooses upon this sentence.

Quoting his own words, "it is now manifestly the duty" of Mr. J. to produce the boy, or give name and address where same may be seen, to those who may be sufficiently interested to pursue the matter further. The existence of a boy capable of giving off electricity without any battery or extraneous source, *when removed from contact with conductors, from the care of showmen and confederates, and specially from any particular room or building* is the logical inference from Mr. J.'s letter.

If there *is* no such boy, or until (with all due respect to Mr. J.) such a boy has been *proved* to exist, by evidence vastly stronger than his, or any other person's, mere unsupported statement, his theories ought to be kept *near* home and well taken care of.

I confess I was myself very much "shocked" when I read his account of the "only way" in which the doses—all of which, I presume, contained "their normal quantities of latent electricity"—"could have" had effect upon the wonderful cow. I have since had his letter thereon (p. 292) tried upon a number of electrical engineers in ordinary normal condition. They have uniformly been "positively electrified" as a result of the "operation," but the "opening" of their pores (?) was apparently due to "local action," specially noticeable in the facial region.

I quite concur in Dr. Stone's last remarks, and for my own part shall take no notice of any more correspondence on this subject, or encroach thereon further on your valuable space.—Yours, &c., HAMLET.

P.S.—Both of the showmen suited their statements to their visitors' idiosyncrasies, but one had special facilities for knowing same.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XXIX.*

We have now discussed the generation of E.M.F. in a revolving armature under the influence of a given magnetic field. We have seen that the E.M.F. is calculated from the rate of change in the total number of lines of force passing through the coils, those due to its own current as well as those due to external field; and we have found that the main effect of self-induction is to add a spurious resistance $\frac{dL}{dt}$, so that the effective or apparent resistance of a spinning armature is no longer R—the value it has when at rest—but $R+4\nu L$, where L is in practice a constant to be determined by experiment, and ν is the number of revolutions per second.

It only remains now to consider the way in which the field is actually produced, and to show how some theoretical approximation to its strength can be made.

Everything depends on the number of lines of force which can be got to go through the armature coils, and it is most important to make them as numerous as possible. The whole power of the machine depends, in fact, upon N, the number of lines which the field-magnet is able to send through the armature.

To Calculate the Value of N in an Ideally Perfect Machine.—Recall certain results already obtained. The number of lines belonging to a simple magnet, or magnetic filament whose strength of pole is m, is $4\pi m$.

The moment of a magnet is ml, where l is the distance between the magnet poles measured straight. In a bar magnet this distance coincides with the length of the magnet; in a horseshoe it does not by any means (*see* Fig. 1). But what-

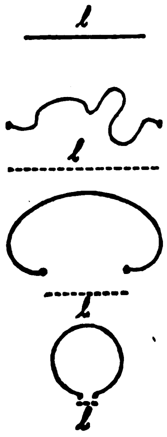

FIG. 1.—Various shapes of simple magnets, and corresponding values of l.

ever the shape of the magnet, l means just the distance between its poles. If the magnet forms a closed curve the value of l is zero, and such a magnet has no moment, though it may be intensely magnetised. If a magnet is bent so that its poles are very near together, l is just the width of the air-gap which separates them.

Now an ordinary magnet has no well-defined poles; or rather, it consists of a bundle of simple magnets, and has a multitude of them. The better and more permeable the steel or iron of which the magnet is made, the nearer will its poles lie to its ends; at least, in the case of a nearly closed horseshoe. For a line has to choose between going through a considerable length of air and going through a rather greater length of iron and then across a short gap of air. With hard steel many lines choose the former course; with soft iron most choose the latter (Fig. 2). Hence it may be said that re-curved electro-magnets approximate more closely to ideal simple magnets than do permanent ones, and the better the iron the more nearly do the lines all go across the shortest air-gap and take no longer path.

Now a dynamo field-magnet ought to form a very nearly closed circuit—at least, when the iron of the armature is taken into account. Hence we shall not be far wrong, and at any

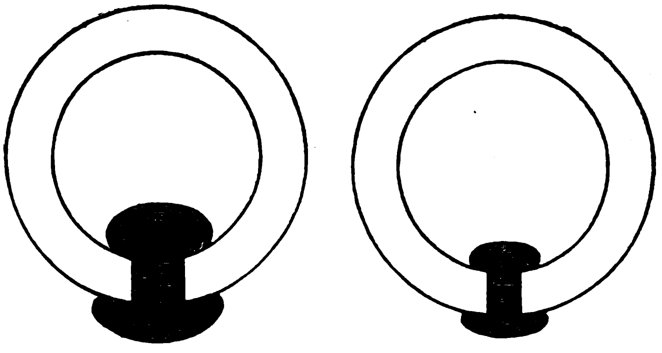
* For Article 28, see *The Electrician*, July 31, 1885.

Digitized by Google

rate we shall be considering the case of greatest perfection, by reckoning l as the total air-gap, *i.e.*, the total width of air which the lines have to cross. It is ordinarily in two halves, one on each side of the armature.

One more thing we have to remember from past work, viz., the magnetic moment of a circuit conveying a current. The area of circuit being A, the number of turns of wire n, and the current C, the moment of a circuit is nAC.

Fig. 2.



Steel magnet. Very soft iron magnet.

This supposes the circuit to contain no iron; if there is iron in it its moment is much more, because of the extra lines induced in, or provided by, the iron. But there are two ways of considering the behaviour of iron in a helix. The more complete way is to take it as introducing a large number of additional lines and adding them to the lines caused directly by the current. A simple way however, which is easily applicable to horseshoe magnets, is to consider the iron only as a nearly infinitely permeable or transparent medium to lines of force, through which lines of force travel almost without resistance; so that the introduction of a bar of iron into a long series of coils welds them altogether as it were into one, and virtually enables us to crowd a great number of windings upon a given small space.

In a dynamo the thing upon which we wish to crowd lines is the armature. One way is to wind the magnetising wire directly over it; but instead of doing this (though this may be advisable sometimes) we can apply a great deal more wire by coiling it upon a large iron bar, the iron being chosen so soft as to offer a barely perceptible resistance to magnetism, and thus to make even the most distant coils nearly as effective as if they were close to the armature.

The softer the iron the more nearly will this be true, and the longer may a magnet be made with impunity. Hard iron magnets must be dumpy. Perfect iron magnets may be any length.

But then it is to be remembered that magnetic capacity of all iron is limited—it tends to become saturated when very strong currents are sent round it. This, therefore, makes a limit to the length of field-magnets beyond which it is not wise to go.

Magnets which are to be saturated should be fairly short. Magnets intended to work far short of saturation may be long.

The iron inside the armature is to be as perfectly soft as the rest—it cannot be too permeable to magnetism, any more than the field-magnet iron can be.

If the iron be all perfect the whole magnetic obstruction is the air-gaps. The best iron may be taken as 1,000, or even 2,000, times as permeable as air. Suppose it μ times as permeable, and that its length altogether is μ times the sum of the air-gaps, then its resistance and that of the air are equal, and l may in that case be considered as twice the air-gap.

Remember, as part of the air-gap we must consider any ill joint, as between the legs of the magnet and its cross piece. Any such flaw throttles the magnetic circuit considerably. All the iron should be of sufficient area, and well jointed together.

Let the sum of the air gaps be a centimetres, the total length of iron in field-magnet be i centimetres, and let its quality be such that it is μ times as permeable as air is. Then, if μ is large and a small, the effective value of the quantity l is

$$l = a + \frac{i}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now put together the equations so far recalled, viz.:—

$$N = 4\pi m \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$
$$M = ml \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$
$$M = nAC \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and combine them algebraically.

The result is

$$N = \frac{4\pi nCA}{l} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and this is the expression we want.

It gives us the whole number of lines of force which the field-magnet produces, and tells us that it is 4π times the ampere-turns, multiplied by the cross sectional area of the magnet, and divided by the air-gap; or by the air-gap plus an allowance for the iron, according to equation (1).

Suppose, however, the whole circuit is not of uniform area, but is throttled in some part, what value are we to give to A? Well we ought to take a kind of average, but a throttle is so important a defect that it is safer to consider that we must take for A the minimum area through which the lines have to pass. This may be in the legs of the magnet, and in some respects *should* be there, because it enables a given length of wire to make more turns.

The minimum area or throttle, again, may occur in the cross-piece of the magnet, and here it certainly should *not* be; if anything can be free and open, this can.

It may occur in the armature, and often does:—not in Edison's with the iron discs, but in Gramme's and Siemens' whose ring of iron is not very thick, it is possible for the throttle to occur in the armature. Siemens, indeed, has his field-magnet iron so thin that the armature is probably always big enough for it; but in a Gramme the cross section of the ring is commonly the smallest part of the iron circuit. In Mather and Platt's recent form this point is much better attended to than in some of the older forms. Of course there is a *double* cross section available in all forms of ring armature.

The worst possible place for the throttle to occur is in the air; but this very seldom happens. All field-magnets have pole-pieces to curve round the armature sufficiently to enlarge the breadth of the air-gap very considerably; and it is well that it is so. In fact, if sufficient area be allowed, the retardation of the air becomes diminished, and formula (1), which supposes the area of iron and air section to be much the same, becomes modified, and something like this:

$$\frac{l}{A} = \frac{l_1}{A_1} + \frac{l_2}{\mu A_2};$$

where l_1 is the width and A_1 the sectional area of the air-gap; l_2 the length and A_2 the mean area of the iron.

But it is scarcely worth while to take note of this small improvement in the formula, though it is very necessary to attend to it in construction.

The simplest and safest rule is to reckon A wherever the magnetic circuit is narrowest, and then apply the formula

$$N = \frac{4\pi n AC}{l}$$

to determine the lines of force; or $\frac{N}{A} = \frac{4\pi nC}{l}$ to find the intensity of field in which the armature revolves.

This latter quantity, 4π times the ampere-turns divided by the air-gap, may be inserted as intensity of field, instead of H, in previously obtained expressions for the E.M.F. induced in a revolving armature.

But one thing we have not yet taken into account: we have supposed the iron infinitely or very highly permeable to magnetism. So it is until it is nearly saturated. We have not taken approach to *saturation* into account.

The customary way of allowing for this is to divide the previous expression by $a + bC$, a linear function of the current passing round it. The constant a in this formula may be con-

Digitized by Google

sidered as nearly unity; the constant b is very small in comparison, and accordingly the term bC only comes into prominence when a magnetising current, or rather the ampere-turns (*i.e.* the current multiplied by the whole number of coils of wire on the magnet), is great. This mode of allowing for saturation can be partially justified by theory, but its best justification is that it accords with experiment. The value of b must be determined for each magnet.

We can now write the expression for the number of lines of force passing through an armature, where C is the magnetising current in the field-magnet coils

$$N = \frac{4\pi n C A}{l(1 + bC)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

ECHOES FROM THE WEST-END.

Ominous rumours are reaching us from Bond street. For months past the public have been looking with expectancy to the completion of a scheme for the distribution of electricity from a central station inaugurated in this district by Sir Coutts Lindsay and Co., but from all accounts an unqualified success relative thereto cannot as yet be chronicled. In a parallel system of lighting on a large scale the cost of the conductors becomes prohibitive, and two other systems, which have each had a public trial, have been devised for the purpose of enabling electricity to be distributed over a large area without incurring in the cost of conductors such a large initial expense. The first of these is the distribution of electricity by the aid of secondary batteries, where the batteries are arranged in local groups charged up by a small current of high potential in series, and discharged in parallel; the second is distribution by transformers, where an alternating current of high potential is employed to excite induction apparatus placed in series or in parallel, the lamps being lit from the secondary coils of the apparatus. The former system possesses, probably among several disadvantages, the advantage of storing electrical energy, and of thus providing against a breakdown in the charging machinery, while the latter enjoys immunity from risks of breakdown due to the absence of liquid conductors in any part of the circuit. The secondary generators, or transformers as they are now more scientifically termed, employed in the Grosvenor district supply are those of Gaulard and Gibbs; and their plan consists in placing the transformers in series over a considerable area, one or more being situated in each establishment to be supplied with light. Each transformer consists of two columns, on which are wound the primary and secondary helices interlaced together, the primary coils of all the apparatus being connected in series and having flowing through them the alternating current supplied from the central station, the secondary coils being employed to light the lamps in parallel.

It will be observed that the great advantage of this system lies in the fact that a small current of high potential can be transformed where required into a current of lower potential suitable for incandescence or arc lamps. If the potential of the primary current is 2,000 volts and the potential of the lamps 100 volts, the value of the system as a means of electrical distribution can be expressed as $\frac{2{,}000}{100} = 20$, where 20 may be called the coefficient of transformation, a value which is important when we consider that within limits the cost of supplying and erecting the mains may be regarded as inversely proportional to this coefficient. Why we lay particular emphasis on this point will be seen presently.

It is only during the last few months that the transformers of Messrs. Gaulard and Gibbs have been constructed on scientific principles. Formerly the two columns of the transformer were magnetically separated from each other, the two straight cores of soft iron wire being simply mounted on a stand with their corresponding helices wrapped round them. Now, however, the pairs of cores are connected together top and bottom, the iron part of the transformer forming a complete magnetic circuit, and having the helices wound on the two vertical sides of the rectangle thus formed. We understand that the dangerous practice of interlacing the primary and secondary helices is still adhered to, although we see no reason why any advantage should be gained from so doing. Where the transformer is of the shape adopted by Messrs. Gaulard and Gibbs we consider that the helices ought to be kept quite apart from each other, the primary being wound on one of the vertical sides and the secondary on the other. This would entirely remove the existing danger of one coil short-circuiting on to the other, and in case of accident the work of removing a faulty coil would be that of a few minutes, whereas now, due to the interlacing of the coils, the whole must be disconnected and taken to pieces before repair can be effected. We see no theoretical objections to the adoption of the plan suggested, and we should like to hear of a trial being made in this direction, as, even in the event of a trifling loss, the immunity from the danger to which we alluded is worth some sacrifice.

But, if report says truly, it is the question of regulation which has hitherto baffled the electricians at Bond-street. The lamps are connected to the transformers in parallel, and as they are turned off the potential rises, to the imminent danger of the remaining lamps, the results of the increase of potential being, in many cases we have heard of, most disastrous. Various have been the devices tried to remedy this evil, but, so far as we can learn, without success hitherto; and, with a view to trying another transformer of his own design, we understand that Mr. Ferranti has lately been placed in charge of the Bond-street station. The designer of the new transformer requires, or rather advocates, a parallel system of primary conductors, but if our information is correct, and if the company contemplate such a change as is implied in the substitution of a parallel for a series system, it is a change of programme with a vengeance. It seems to us that with parallel conductors the transformer system for general distribution is robbed of the very advantage which makes it of value, since by this modification the coefficient of transformation is at once brought down to $\frac{200}{100} = 2$. The limit 200 being the E.M.F. which can, by the Board of Trade regulations, be allowed between two points in a building. It is surely not proposed for one moment to work a parallel system where the primary has a difference of potential of 2,000 volts. Not only are the risks of breakdown increased with parallel connections, but the briefest examination shows the proposal to be so absurd that we hesitate to believe it has ever been made. We are not in possession of all particulars relating to the new transformer, but from the description given to us it differs in no essential point from that of Gaulard and Gibbs. What can be done with the former can be done with the latter, and the solution of the regulation question seems to reside in the mode of coupling up the apparatus. We have no exact information on the point, but it appears to us that for a series system to be successful the lamps must be coupled in series from the secondary coils, while for a parallel system it is requisite that the lamps be coupled in parallel.

We trust that whatever method be employed to effect the purpose in view we shall soon silence those muttered curses against the electric light so often heard in Bond-street. It would do much to reassure the West End public if the system could be now declared perfectly successful, and we trust that ere long we shall be able to chronicle a triumph which will do credit to all concerned.

A CHARGE INDICATOR FOR STORAGE CELLS.

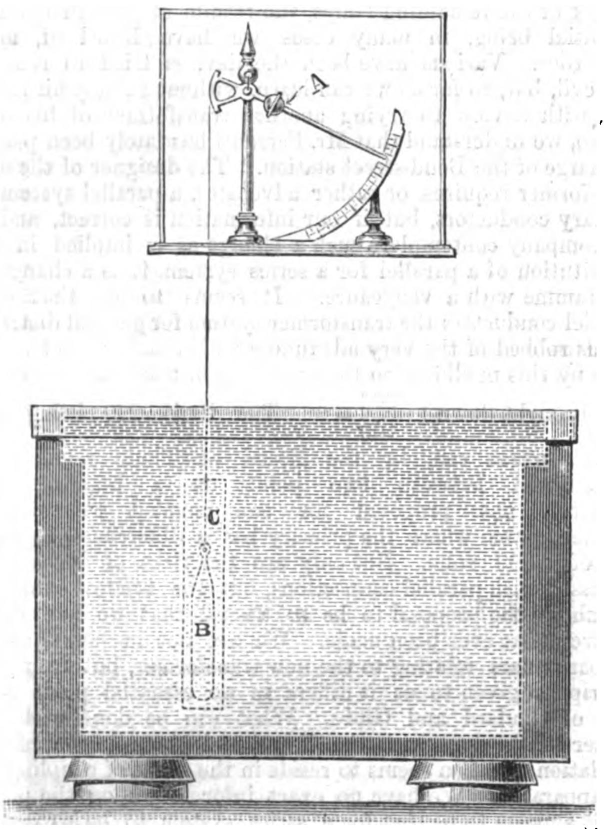
The Elwell-Parker secondary battery gauge, or charge indicator, is for automatically closing the charging circuit when the cells are exhausted, and breaking it when they are fully charged; also for continously showing the condition of the charge and signalling it by a bell or otherwise.

Prof. Forbes, at the Society of Arts, drew attention to the necessity for a reliable indicator, actuated by the change in density of the liquids for automatically working a switch, and he was not aware that any such was in use. The

Digitized by Google

following description of the apparatus used by Elwell-Parker (Limited) may consequently be of interest:—The instrument is designed upon the principle of the hydrostatic balance and is patented by Mr. Thomas Parker. It has been used in connection with the Elwell-Parker accumulators during the past two years with perfect success. It is unaffected by the level of the solution, and does not require a special cell.

It consists of a vertical brass pillar from which projects a horizontal arm, carrying by two silk cords the beam, at one end of which is the segment of a wheel, the axis of the beam forming the centre, and at the other end is an ivory pointer and an adjustable balance weight. A glass bulb, B, hermetically sealed, and loaded so as to *just* sink in the solution when at its greatest density, is suspended in the centre of the cell by a platinum wire attached within the gauge case to a silk cord hanging from the segment on the beam. The gauge, entirely enclosed in a glass case, is placed upon a shelf directly above the cell, so that the glass bulb hangs in the solution without touching the plates.



The Elwell-Parker Secondary Battery Gauge.

It will be at once seen that, as the battery is being charged and the specific gravity of the solution increases, the bulb B will rise and the angle formed by the arm bearing the balance weight A with the vertical pillar will become more acute until the pointer reaches the bottom of the scale, when a cross bar formed by a fine piece of platinum wire at the end of the pointer comes into contact with two upright platinum terminals, and so closes the circuit either of an electro-magnet switch (for automatically cutting the battery out of the general charging circuit) or of an electric bell in the engine house (to show that the charging is complete), or where a gas engine is used to cut off the gas and so stop the engine. A similar contact may be made when the cells are exhausted (to any desired extent), and the charging circuit thrown in again, or a bell sounded by the pointer reaching the top of the scale.

As the capacity of a secondary battery, when always discharged in series, depends upon that of the weakest cell it contains, and as every cell will require exactly the same amount of current to recharge it, a single indicator placed over any cell is all that is required.

DYNAMO TESTS.

(Continued from page 315.)

From the preceding table and the dynamometer record, we get the following data:—

Mean reading scale beam	655·9195
Mean friction reading	13·72
Corrected reading	642·1995
No. revolutions	106·180
Foot pounds absorbed............	225585395·

Heat units passing through cal. (uncorrected)	157735·96
Heat units radiated from calorimeter ....+	4045·89
Correction to reduce ther. to abs. temp. .... –	169·63
Stem correction ....+	647·12
Total heat units..............................	162169·34

Mechanical equivalent for 1° C. ... 1391·05 foot pounds.
Mechanical equivalent for 1° F. ... 772·81 foot pounds.

In this method the uncertainty due to the specific heat of the iron and its temperature is avoided. The greatest possibilities of error are in the mean temperature of the calorimeter and the stem correction. It is probable that too great a value of the latter has been taken; for the thermometers were in the water for several hours, and a considerable portion of the stem must have been heated by conduction.

The co-efficient of radiation was taken from the first experiment.

The results of the experiment are:—

First method mech. equiv. = 768·3 + an indeterminate correction.

Second method mech. equiv. = 772·81.

It would seem, then, that within the limit of error of these experiments, the dynamometer is correct, and, considering the probable accuracy of the last method, there seems little doubt that the work calculated from the dynamometer readings is as accurate as the adjustments of the machine and the readings themselves.

TESTS.

For the full load tests, the machines were run at least ten hours before any measurements were made. They were then tested at intervals of from one to two hours.

For the partial loads, the dynamos were run on quarter load for two or three hours, then tested, then run on half load for a couple of hours, and tested, &c.

The method of making a test was as follows:—A time to begin was set, and the observers got ready to start at the signal from the test house. After the signal, double readings of the potential and current galvanometers were simultaneously made each minute, and the scale beam and number of revolutions of the dynamometer observed. The field galvanometer was reversed, and read as often as possible, usually four or five double readings.

At the end of ten minutes a signal to stop was made; the dynamo was stopped, the field circuit broken, the storage battery put on, and the armature resistance measured. The brushes were then lifted, and the field circuit made and its resistance measured. Finally, the constants of the current and potential galvanometers were checked on the German silver strips.

When the tests for the day were finished, the friction of the armature and of the dynamometer was obtained, and the latter subtracted from the power applied for each test.

Communication from the test house to the dynamo shed was by an electric bell, and through a speaking tube.

The following notation will be used in the formulæ:—

- e difference of potential between terminals of dynamo;
- E total electromotive force generated in armature;
- i current in external circuit;
- i_s current in field;
- R resistance of external circuit;
- r_a resistance of armature coils;
- r_s resistance of field with box for adjustment;
- S resistance of field alone;

W energy applied in horse-power;
W_t total electrical energy in horse-power;
W_e energy in external circuit in horse-power;
W_a energy in armature in horse-power;
W_s energy in field in horse-power;
Ef_t total efficiency of electrical conversion;
Ef_c useful commercial efficiency;
η $= Ef_c / Ef_t$;
p_a percentage of power used in armature;
p_s percentage of power used in field;
n number of revolutions per minute;
Fric. friction of armature;
t_a temperature of the air in degrees centigrade;
t_p temperature of pole-piece in degrees centigrade;

Of these, e, i, i_s, r_a, S, W, n, t_a and t_p, were observed directly.

E was calculated from $E = e + (i + i_s)\, r_a$;

R was obtained from $R = e / i$;

r_s was from $r_s = e / i_s$; it was also checked by observation after each test.

The other formulæ used were—

$$W_t = \frac{(i + i_s)\, e + (i + i_s)^2 r_a}{745 \cdot 3}$$

$$W_e = \frac{i\, e}{745 \cdot 3}$$

$$W_a = \frac{(i + i_s)^2 r_a}{745 \cdot 3}$$

$$W_s = \frac{i_s\, e}{745 \cdot 3}$$

$$Ef_t = \frac{W_t}{W}$$

$$Ef_c = \frac{W_e}{W}$$

$$\eta = \frac{Ef_c}{Ef_t}$$

$$p_a = \frac{W_a}{W}$$

$$p_s = \frac{W_s}{W}$$

EDISON NO. 5 DYNAMO.

This was the first machine tested, and the measurements were intended as much to show any weak points in the method as to serve as a test of the dynamo. If no trouble occurred, the work was to be accepted, otherwise it would have been repeated after the causes of error had been removed.

Diameter of armature	$7\frac{1}{16}$in. inner; $7\frac{7}{8}$in. outer.
Weight of machine	2475 pounds.
Number of commutator bars	50
Turns of wire in a coil	2
Length of useful wire in a coil	52in.
Brushes adjusted or not?	Yes.
Diameter of bearing	$1\frac{5}{16}$in.
Length of bearing	$5\frac{5}{8}$in.
Revolutions per minute	1400
Volts for best work.........................	125
Amperes for best work	100

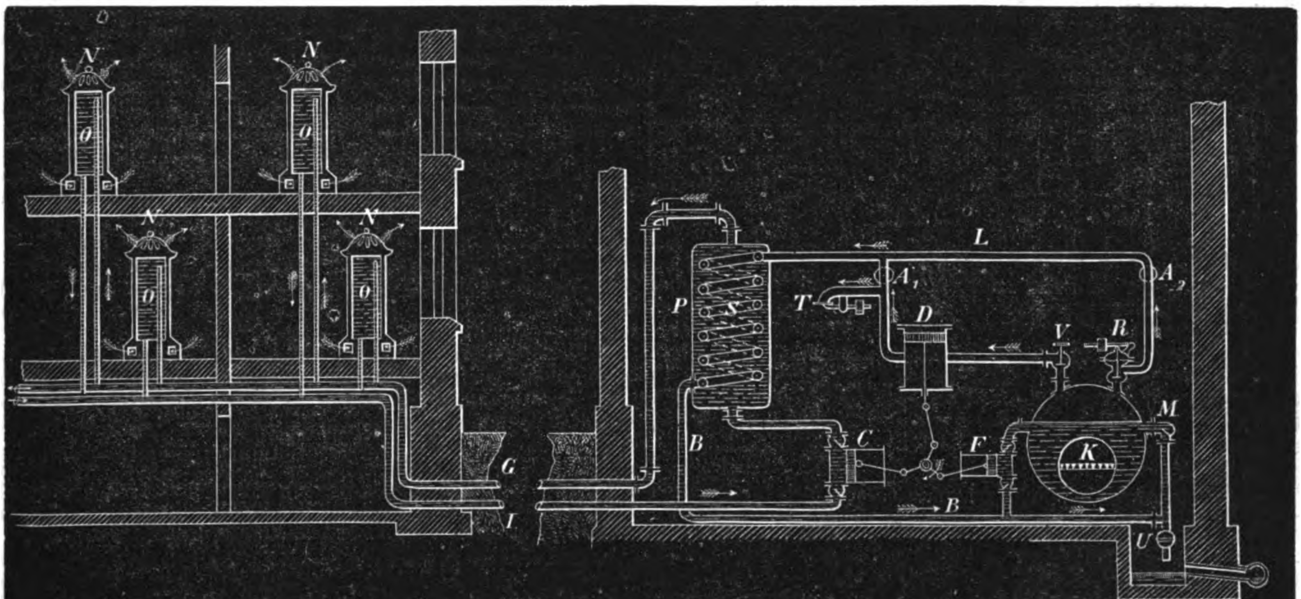
RECK'S SYSTEM OF COMBINED ELECTRIC LIGHTING AND HEATING.



The electric light often gives much disappointment from an economical point of view, which cannot be wondered at when it is borne in mind that this light is often recommended for places not at all suitable for its use. The future of the electric light would no doubt be better secured if it were introduced in places where a favourable economical result could safely be depended upon. Particularly would this be the case in a building heated by steam from a heating apparatus constructed to make use of the exhaust steam from the steam motor of a dynamo machine supplying electricity to the electric

Digitized by Google

lamps in the building. The requirements for heat and light being almost equal during the same part of the year, a building would, by an arrangement as the one above-mentioned, be heated and at the same time lighted by electricity at a very small cost. The reason why this profitable combination of electric lighting and heating of a building by exhaust steam has not yet been generally adopted must be looked for in the fact that the direct application of exhaust steam for heating purposes, by circulating the steam itself through pipes placed about the building, is defective in two essential ways. Firstly, exhaust steam cannot profitably be carried far from the boiler, partly because the large pipes required by the exhaust steam are expensive, and partly on account of the great waste of heat at places situated outside the localities to be heated. Then most heat is generally required at a time, viz., the morning, when no light is required; and when an effective light is wanted there is often no use for all the heat contained in the exhaust steam. These defects are done away with by the indirect heating by exhaust steam, as proposed by Mr. Reck. The figure shows an arrangement by which Mr. Reck proposes to store heat from the exhaust steam by employing it to heat a reservoir of hot water. K is the boiler; R a reducing valve supplying the necessary steam from the boiler when more steam is required than can be got from the engine; T is a safety-valve letting out the surplus of exhaust steam if the engine supply more than required for heating; A_1, A_2, and V are common stop-valves. The exhaust steam passes from the cylinder D to the coil of pipes S, by means of which its heat is transferred to the water in the tank P; and by means of a pump C this water is kept circulating from the tank P through the pipe G to the heating-coils O in the building, from which it again returns through the pipe I to the tank P. F is the feed-pump. The dynamo machine which supplies the electric current to the lamps is not shown in the wood-cut. By an arrangement of this description the electric light might be obtained in a country house at a comparatively small cost.

Messrs. Capito and Hardt, of Queen Anne's Gate, Westminster, are the agents for Mr. Reck's system.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The resumption of the discussion on the President's inaugural paper took place on Thursday evening, 25th February, at the Institution of Civil Engineers. Prof. Hughes, F.R.S., again withdrew from the chair, which was taken by the late president, Mr. Spagnoletti, who announced that Mr. F. H. Webb, the secretary, had been appointed editor of the Society's *Journal*, Prof. Ayrton having retired from that position.

Mr. W. H. Preece, F.R.S., then continued the discussion adjourned from the previous meeting, speaking in eulogistic terms of Prof. Hughes's investigations, which, he said, threw considerable light on many obscure problems that had perplexed and hindered electrical engineers from the very first. Self-induction had always been the *bête noir* of practical telegraphists, and the necessity for getting rid of it grew more urgent as greater needs arose for increasing the speed of telegraphic signalling. He had himself worked experimentally with this object in view a good while ago; and as far back as 1877 he had read before this Society a paper bearing the title "On Shunts," which had a close relation to the subject now under discussion, but which was eclipsed at the time by the sudden appearance of the telephone, and had since been lost sight of. That paper gave the results of a lengthened investigation into the properties and behaviour of self-induction, due to electrostatic and electro-magnetic causes. As to the latter, he described it as being similar in effect to inertia in dynamics, and since that date the phenomena have been commonly spoken of as due to electro-magnetic inertia. Electricity is a form of energy, and when an electric current passes along a conductor where another conductor is in the magnetic field of that current, energy is set up in the latter at the expense of the magnetic field itself. Certain French experimenters had drawn attention to the fact now explained by the President that the speed of the current differed in iron and copper; and an Italian scientist had pointed out a difference also in respect to the different speed at which the current travelled when steady and when intermittent. But he (Mr. Preece) had devoted his experiments chiefly to apparatus employed for telegraphic purposes. At that time there was no more delicate form of indicator than the reflecting galvanometer, nothing nearly approaching the sensibility of Prof. Hughes's appliances being then even imagined. But with the means at his disposal he made some curious discoveries, which had proved extensively useful in the sphere of practical telegraphy. Explaining diagramatically the method pursued, Mr. Preece showed that by taking the self-inductive effect of one coil of an electro-magnet as a standard of unit, the result of adding a second coil in series was to increase the effect 17 fold; by adding a piece of iron across the bottom poles of the two coils the effect was increased by 496, and by the addition of a similar piece on the top the increase was 2,238. The bearing of these facts on the construction of Relays became evident when it was found that by cutting these two pieces of iron in half at top and bottom the effects of self-induction were enormously diminished. It was also noticed that they were reduced at least one-fourth when the coils were joined in quantity. The Relays then commonly in use varied immensely in their practical usefulness, though their construction and plan appeared faultless. After these experiments, however, they were able to construct apparatus of this class which admitted of vastly increased speed of working. More recently the galvanometer had been cut out at the suggestion of a Bristol telegraphist, who noticed that "sparking" was got rid of when that portion of the apparatus was dispensed with. As regards telephone working, the chief difficulty was overcome by doubling the wire, and Prof. Hughes had now shown that twisting it was even more efficacious. Some very costly experiments had been made by the Post Office to test the possibilities of of long distance telephony between London, Liverpool, and Manchester. The wires were of iron, however, and failed. If they had been of copper, possibly the experiment might have succeeded. The question of stranded iron wire was not likely to materially alter the existing arrangements, for a stranded wire affords the best lodgment for snow, as was found during the recent storms, when lines of that description were the very first to succumb. They are not so durable, and on other grounds it is unlikely they will be preferred to copper. Amongst other means that had been devised for curing lines of self-induction, the speaker described that in which the Relay is connected to earth through a condenser, and "bridged" by a balancing resistance, the adjusting being so managed that the current from the condenser cuts off or neutralises the effect of line induction. In conclusion, Mr. Preece contrasted the laborious and expensive trials undertaken by his department and the decisive results obtained by the simple but marvellously sensitive instrument before them, guided by the genius and unerring instinct of its inventor, Prof. Hughes.

Dr. Fleming spoke at some length with reference to the bearing of the experiments on the time constant of a magnetic coil, and their value in determining the coefficient of its self-induction. In venturing to explain some of the phenomena appearing on stranded wires, he pointed out that by cutting the circle of a conductor, giving it a serrated edge, which is the practical outcome of stranding, the magnetic permeability is interrupted and its self-inductive properties greatly reduced. If we could manufacture a serrated wire by, say, drawing it through a die, giving it a section like that of a pinion wire, the effect would in all likelihood be the same. Expressing his high appreciation of the President's labours, Dr. Fleming respectfully suggested that as a term is wanted to express the unit of self-induction no more fitting or appropriate designation could be found for it than the "Hughes."

Mr. Desmond FitzGerald drew attention to his paper on the electric polarity of a current, published in 1870. He pointed out that between the inlet of the current and its manifestation on the conductor there is an appreciable interval; and that it is in this interval that the birth of electro-magnetism takes place, the magnetic effects preceding in reality the actual passage of the electric current. But the subject would require too much time to do justice to it in a brief speech, and he would reserve his observations for a more favourable opportunity.

Prof. Silvanus Thompson, while endorsing everything that had been said in admiration of Prof. Hughes's beautiful experiments, thought we ought to be careful to take into account the rate of variation in the current manipulated under the intermitting clockwork of this apparatus; and to ask him particularly whether any difference were noticeable in the results when a high speed and when a low speed respectively was employed. He, himself, would have preferred some definite number of vibrations, say those of a particular musical note. He illustrated the importance of this consideration in relation to what have been called the spurious resistances in alternate current dynamo machines as well as in telephonic working. He questioned the accuracy of Prof. Forbes's explanation offered at the last meeting, and pointed out that the pinion or stranded pattern would possess no advantage in the case of copper wire. For telephone circuits, he was clearly of opinion that iron wire should never be used, and stated that three years back he had advocated the employment of silicate bronze.

Prof. Ayrton, after some observations on what had fallen from the previous speaker, confessed that, although he could not concur

Digitized by Google

in the view that theory and mathematics always came after experiment and practice, he had latterly been led to the conclusion that there were certain phenomena of nature which mathematical calculations could not reach or explain.

Prof. HUGHES, having only time to say a few words, it being then after ten o'clock, promised to commit his observations to writing for publication in the Society's *Journal*. But, in reply to Prof. Thompson, he stated that at all speeds within the limits of the interrupter no difference of results had been observed.

The CHAIRMAN, in closing the proceedings, announced that the Society would be glad to receive communications on the subject from any gentlemen who had wished, but had been unable, to join in the discussion.

PHYSICAL SOCIETY.—February 27th.

Dr. J. H. GLADSTONE in the chair.

Dr. Sydney Young and Mr. D. E. Jones were elected members of the Society.

The following communications were read:—

"The Relations of Pressure, Temperature, and Volume in Saturated Vapours," by Prof. W. C. UNWIN. In the first part of this paper certain formulæ given by Messrs. Ramsey and Young in a recent communication on "Some Thermodynamical Relations" are criticised. The most important of these is the statement that for different saturated vapours at the same pressure $p\frac{dp}{dt}$ is constant. Prof. Unwin finds, however, that $t\frac{dp}{dt}$ is less constant than $t^2\frac{dp}{dt}$, while $\frac{t^2}{p}\frac{dp}{dt}$ is nearly a constant quantity for all saturated vapours under any conditions. This result suggested that $\frac{t^{n+1}}{p}\frac{dp}{dt}$ might be more nearly constant, and the integration of this gives

$$\log. p = a - \frac{b}{t^n}$$

a formula to the examination of which the second part of the paper is devoted. From it may be derived the following relations, in which for convenience in calculation the logarithms given are to the base 10.

$$t = \left(\frac{b}{a - \log p}\right)^{\frac{1}{n}}$$

$$\frac{1}{p} \cdot \frac{dp}{dt} = 2{\cdot}3025\,\frac{nb}{t^{n+1}}$$

$$= 2{\cdot}3025\,n\,\frac{(a - \log p)^{\frac{n+1}{n}}}{b^{\frac{1}{n}}}$$

$$\frac{t}{p} \cdot \frac{dp}{dt} = 2{\cdot}3025\frac{nb}{t^n}, \text{ \&c.}$$

These formulæ have been examined in the case of steam from 30° to 230° C., and with pressures varying from ·4 to 20 000 mm. The constants were found to be

$a = 7{\cdot}5030$ $b = 7579$ $n = 1{\cdot}25$

and the differences between the calculated results and the observations of Regnault and Zeuner rarely exceeded 1 per cent., while generally much smaller.

a, *b*, and *n* have also been found for some other substances, with the following results:—

Alcohol.................	$a = 7{\cdot}448$	$b = 8784$	$n = 1{\cdot}29$
Ether	$a = 6{\cdot}9968$	$b = 3047$	$n = 1{\cdot}153$
Mercury	$a = 9{\cdot}8651$	$b = 597{\cdot}5$	$n = {\cdot}69$
Carbonic acid	$a = 8{\cdot}4625$	$b = 302{\cdot}8$	$n = {\cdot}77$

Prof. PERRY offered some criticisms upon this paper, and believed that for practical purposes the expressions given would not be found superior to Rankine's formula

$$\log p = a - \frac{b}{t} - \frac{c}{t^2}$$

which gives p in terms of t, and a quadratic expression for obtaining it in terms of p. He also observed that the chief aim of Ramsay and Young's paper was to obtain relations between the pressure and temperature of different saturated vapours, so that the connection between temperature and pressure having been observed and recorded for one vapour, that for any other vapour could be at once deduced from it.

"On a Map of the World, in which the Proportion of Areas is Preserved," by Mr. WALTER BAILEY. The author had devised a method for constructing such a map, but has subsequently found that one precisely similar was employed by Flamsted in 1729 for charting the stars in his "Atlas Celestris." The construction applied to the earth as briefly as follows:—Draw a straight line to represent the meridian that is to occupy the centre of the map. Divide this line into equal parts, representing upon a convenient scale the distance between the parallels of latitude, and through these points draw a series of lines at right angles to the original line; these are the parallels of latitude. Mark off on these the actual distances at which the meridians cut them; through the points so found the meridians may be filled in and the map constructed. From the method of construction it is evident that although the outlines in the map are distorted, the amount of distortion increasing with the distance from the central meridian, the proportionality of areas is preserved, a fact which the author believes will render the map useful for recording rain-fall, depth of sea, ocean currents, &c.

"On a Delicate Calorimetric Thermometer," by Prof. S. U. PICKERING.

COMPANIES' MEETINGS.

Telegraph Construction and Maintenance Company (Limited).

The twenty-second ordinary general meeting of the members of this Company was held at the offices, 38, Old Broad-street, E.C., on the 2nd inst., Mr. Philip Rawson, J.P., presiding.

The MANAGER (Mr. William Shuter) read the notice convening the meeting and the minutes of the last ordinary and half-yearly general meetings, which were signed as correct by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I am sure you will regret quite as much as I that our worthy Chairman is not present to day, but about an hour ago we received a note from him to the effect that his doctor would not allow him to go out in this inclement weather. We have no reason to believe that he is seriously indisposed, but you all know how very trying the weather has been, and as a matter of prudence his medical adviser has counselled him to keep at home. I may mention as an interesting fact that Sir Daniel Gooch has presided at 45 consecutive meetings of the Company, and this is the first meeting which circumstances compel him to be absent from. I regret his absence all the more as I am called upon to preside at this meeting at very short notice indeed. I myself have been confined to the house for three weeks, and I feel that I may very fairly call upon you for your indulgence. However, it is always pleasanter, or, rather, it is a much easier task, to preside at any meeting where the company is prosperous, and I think I may fairly say that our Company has been very prosperous, and I can sincerely congratulate you. The report and the figures are drawn exactly upon the same lines as you have been accustomed to receive them, and there is very little for me to say. The accounts, as you perceive, show a net profit of £82,740, and adding the £72,166 brought forward there is a total of £154,907 to be dealt with. That enables us to declare the usual dividend of £1. 16s. a share for the half year, making with the interim dividend 20 per cent. for the whole year, and to carry over the very substantial sum of £65,267. To pass on to the next paragraph—the operations carried out in 1885—I think it has been mentioned, and is within your knowledge, that early in the year the Government entered into a contract with this Company for the manufacture of 1,000 miles of cable. The cable was manufactured and completed in May, and has been paid for. At the same time the Company manufactured 322 miles of cable, which they laid from Shanghai to Port Hamilton, the new coaling station off the coast of Korea. That cable was successfully laid, and we have received the money for it. We also manufactured 740 miles of cable for the Eastern and South African Cable Company, which we laid in August as a duplicate line between Zanzibar and Mozambique. It has been covered with the new brass tape, which is a perfect protection against the teredo, the little insect which has been so very destructive to cables in some parts of the world. The Heligoland-Cuxhaven cable was partially relaid and put in good working order. That was a small matter. The next two points in the report refer to the cable which has been laid to the Fastnet Rock from Crookhaven; and to the cable connecting the "Sunk" Lightship from Walton-on-the-Naze having been successfully maintained, with but slight interruption. Those were experiments, and particularly as regards the "Sunk" Lightship. We had great difficulty at first in keeping up the communication, but our electricians and engineers have, I believe, now got quite over the difficulty; and at the date of this report the "Sunk" Lightship connection had been maintained for 306 out of 311 days. There are also various lengths of cable, amounting to 763 miles, which we have manufactured for different telegraph companies and colonial Governments. The steamships "Calabria" and "Kangaroo," which were chartered by the Government for a long time in the Red Sea, have now been discharged, and are both in the Thames. I do not think there is anything else in the report which calls for further remark. I may mention, with reference to future work, that we are manufacturing a cable 550 miles long for the Eastern Extension Company, to be laid between Singapore and Penang. There is also a considerable contract with the African Direct Cable Co. for 2,000 miles of cable. The contract itself is all completed, and is only awaiting signature until the subsidy, of which you have no doubt read a good deal in the papers, is confirmed by Parliament. We have also one or two other small matters in hand which, however, I need hardly allude to. I have much pleasure in moving this resolution:—"That the report and accounts of the Directors to the 31st December, 1885, submitted to this meeting be, and the same are hereby, received and adopted, and that a dividend of 36s. per share, in addition to the 12s. a share interest, or interim dividend, paid to June 30, 1885, be paid upon all the shares of the Company for the year ended December 31, 1885, and that such dividend be paid free of income tax."

Mr. GEORGE W. CAMPBELL briefly expressed his pleasure in seconding the resolution.

Mr. WM. ABBOTT said he was sure that he expressed the unanimous feeling of the shareholders when he regretted that the worthy Chairman of the Company (Sir Daniel Gooch) was indisposed. At the same time they were all aware that one of the characteristics of Sir Daniel was extreme caution, and he was extremely judicious in anything he undertook. He was very pleased to know that that cautiousness had prevented Sir Daniel Gooch from leaving home that day. There was one matter in

Digitized by Google

connection with their affairs on which the report was silent, and as to which he would be glad if the Chairman would give them some information. He referred to the important matter of the electric light. There was no doubt that their Company held a forefront position as to cables and everything else electrical. They had capital at their back, and their officers were experienced men, of long-standing and high training; and, therefore, he wished to know why it was that electric lighting stood still. Was it that Mr. Chamberlain's Bill had completely killed this enterprise? When they heard so much about the unemployed in London, and knew that there was an enormous amount of capital seeking employment, it did seem strange that such a great enterprise as electric lighting, which was making such extraordinary strides in every country but England, should remain stationary; and he thought they ought to have some authoritative statement from the Chairman as to why it was that the report was silent on such an important matter. He had no hesitation in saying that if a comprehensive scheme were propounded which would give capitalists a chance of securing a fair return on their money for a certain number of years, any amount of capital could be obtained for the enterprise, which was so very important to the community at large. As to the Lightships, he presumed that that was a matter which was now entirely in their hands, and he foresaw that it would be a business for which there was a very large development; for not only would Lightships be connected with the Post Office telegraph system, but also all the Lighthouses. This would be a very important matter to the marine interests of this country. He had nothing further to say except to compliment the Directors on the very small amount of transfer fees, showing that they had, although a large proprietary, a thoroughly contended one.

The CHAIRMAN: Mr. Abbott has alluded to Mr. Chamberlain's Act, and I think there can be no doubt whatever that that Act has been a very great clog on the electric light enterprise. As to our own system of electric lighting, we have said nothing about it, because we have not completed our experiment. We have met with a great variety of little difficulties, all of which I believe have been removed; but our greatest difficulty has been in connection with the inhabitants surrounding the Paddington station. That is a difficulty the end of which I do not exactly know. As far as we are aware, however, the inhabitants there have been quiet for a long time; but what may happen when we get our machinery "in full swing" I cannot say. We hope the matter will be all straightforward and right, and that all difficulties will be removed. If there is no other question I will put the motion. No other shareholder rising to address the meeting, the resolution was put and carried unanimously.

On the motion of the CHAIRMAN, seconded by Vice-Admiral Sir GEORGE H. RICHARDS, C.B., F.R.S. (the Managing Director), the retiring Directors, Lord Alfred Paget and Mr. George William Campbell, were re-elected, as were also the Auditors, Mr. John Gane and Mr. James Glegg.

Mr. WILLIAM FORD then remarked that it was some years since he attended a meeting of the Company, and it was a great satisfaction to him, as he was sure it was to his co-proprietors, that it had survived some of the advice which years ago he had ventured to give them. They had to thank the Directors for having rejected much of the advice which he then offered to them, for he feared that if they had followed some of the juvenile precepts which he had ventured at the period referred to to force on their minds, the happy result announced in the report would not have been consummated. He might state that at the date in question he had been most strongly in favour of the utmost publicity in the Directors' reports—that they should communicate to the shareholders every possible tittle of information that could be given. He recanted that view as an error. Many things had happened since then. Important competitors had grown up for the manufacture of cables, and he ventured to say that the information contained in their reports too frequently gave to their competitors an insight into transactions in the business of the Company which, as competitors with them, it was exceedingly indiscreet for them to give. He ventured to say, by way of illustration of what he meant, that if he had had the preparation of the report which had been submitted to them on the present occasion, he would have omitted paragraph 3 and sub-sections A to F, and would have simply stated this: "Various important contracts have been entered into and successfully and profitably executed during the course of the year." Any further information which shareholders taking an interest in the affairs of the Company desired might doubtless be obtained by applying to their able manager, Mr. Shuter. He did not intend to make his observations the basis of a resolution for the guidance of the Directors; but it was his opinion—and he believed that the experience of the gentlemen at the Board would confirm this view—that in a manufacturing company of such a character as theirs, having powerful competitors, it was not discreet always to tell who their customers were, or what amount of work they had done for them. Indeed, in the case of private undertakings, some customers would greatly object to have the information of the business they transacted communicated to the public. There were many matters in the report of imperial importance which he thought it would have been exceedingly discreet to have omitted, but which he feared some of the shareholders, of his own previous juvenile way of thinking, would not like to have had dispensed with. What he had said was a mere prelude to a vote of thanks which he desired to propose to their able chairman, Sir Daniel Gooch, whose indisposition he exceedingly regretted, and, indeed, but that he had expected to have the pleasure of meeting Sir Daniel, he would not have been in the city that day. He desired to convey to him and the other members of the Board the high appreciation which the shareholders held of their valuable services. After the lapse of so many years it was a great pleasure to him to see that the Company still enjoyed the advantage of the very able assistance which they derived from their energetic and able manager, Mr. Shuter; and also that they still benefited by the skill and magnificent abilities (he used that expression not as a mere figure of speech, but from his knowledge of the fact) of Mr. Willoughby Smith and Mr. Clifford. He might also add the name of Captain Halpin, and of other gentlemen connected with the Company—men of the highest honour and integrity, who had served the Company well and ably. He hoped they would remain with the Company for many years, to their own profit and the profit of the shareholders. He did not believe that the Directors would consider him in any way wanting in respect to them in associating their names with the names of the other gentlemen he had mentioned. He concluded by proposing a cordial vote of thanks to the Directors, associating with the vote the names of Mr. Shuter, Mr. Willoughby Smith, Mr. Clifford, Captain Halpin, and the other officers of the Company.

Mr JOHN NEWTON seconded the motion. He thought that the shareholders had received such substantial benefit from the Directors that they might place their affairs entirely in the hands of those gentlemen. Indeed—alluding to Mr. Ford's remarks—if they simply announced the dividend to the shareholders the latter would be perfectly satisfied; but such sentiments or principles could, he maintained, only apply to a company which had given such evidence of progress as theirs had. A trading company could at all times, if it desired to do so, announce facts when they had been accomplished, retaining only such information as would be of advantage to their opponents. When, however, the Telegraph Construction and Maintenance Company obtained a contract all their opponents knew it—they would not be such fools as not to know it. The Company's work was of such a splendid character that they carried all before them.

The resolution was carried unanimously.

The CHAIRMAN: On behalf of the Directors and the other officers of the Company whom you have so highly eulogised I beg to return you sincere thanks. I am quite sure that the exertions they have used in the past will be fully at the disposal of the Company in the future, and that nothing will be wanting on their part, or on the part of any of us, to maintain the continuance of the success we have hitherto enjoyed.

The proceedings then terminated.

NOTES.

Mechanical Telephones.—The Byng Telephone Company has been registered. Its capital is £5,000 in £10 shares.

Obituary.—The death is announced, in France, of M. Auguste Guérout, well known in connection with *La Lumière Electrique.*

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 5th inst. amounted to £3,357.

The West Coast of America Telegraph Company.—The gross earnings of this company for the month ending February 28th amounted to £3,300.

Electric Steering Gear.—The U.S. steamer "Tallapoosa" has arrived at Fortress Monroe from New York, after a successful test of her electric steering gear.

Gas in Paris.—During January last the receipts of the Parisian Gas Company were diminished 1 per cent. This was due to the growing usage of the electric light.

Canada.—The superintendent of Government telegraph lines in the Canadian North-West states that a new line will be erected between Battleford and Fort Pitt in the summer.

The American Telegraphs.—The House Committee on Post Offices and Post Roads has unanimously agreed to report adversely all Bills before it for the purchase or construction of telegraph lines by the Government.

The Telephone in Austria.—Advices from Vienna state that as a practical result of the experiments recently carried out between that town and Brünn, telephonic communication will be permanently established.

The Electric Light in France.—It is proposed to install the electric light in the Bon Marché and the Gare de l'Ouest. The Bourse and the mansions in its vicinity will also, it is thought, adopt the new light.

Earthquake Shocks in Egypt.—A telegram from Cairo states that a shock of earthquake was felt there at half-past ten o'clock on Wednesday night last week. There was another shock on Thursday morning at six o'clock.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended March 5th were £2,724, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

The Telephone in London.—At the last meeting of the Fulham Board of Guardians, an offer was considered from the United Telephone Company for laying on wires for use in the clerk's office, infirmary, workhouse, and porter's lodge, at a cost of £28 per annum. The matter was referred to committee.

The Police and the Telegraph.—Orders have been issued to all Postal Telegraph offices in the metropolis that messages are to be accepted without prepayment when tendered by officers of the police force within the Metropolitan Police district, and addressed to Scotland-yard on police business.

New Zealand.—Advices from New Zealand state that the other day the Cable Company submitted certain propositions to the Government with respect to the subsidy and tariff, which were not entertained, and the Government has cabled the Agent-General to ascertain the cost of making and laying a new cable.

Liquidation.—A petition for the winding-up of the Consolidated Electric Company has been presented to the High Court of Justice by William Morrison and Sons, of 96, Leadenhall-street, E.C., creditors of the company; and the petition is directed to be heard before Mr. Justice Pearson, on Saturday, the 13th inst.

Portugal.—The Gas and Light Company of Portugal was registered on the 16th ult., with a capital of £100,000 in £5 shares. Its object is to carry on in Portugal, the Portuguese possessions, or elsewhere, the business of gas manufacturers and electrical engineers, and every other business connected with the manufacture of gas and electricity.

The Central Station at Milan.—The central station in Milan, installed by the Société Italienne Edison, now possesses eight Edison dynamos, 1,000 16 candle-power lighters, supplying current to 7,921 lamps. On the 1st of January, 1885, the number of lamps installed did not exceed 5,530. Arc lamps to the number of 101 are also variously installed.

Post Office (24th Middlesex) Rifle Volunteers.—The following men of this corps are announced as having passed their examination in flag signalling at Aldershot last August, and as now being entitled to wear the badge:—Staff-sergeant W. R. Williams, Sergeants R. E. Kemp and T. Pusey, Corporal W. Ruckman, Privates W. Malion, L. D. Barclay, and D. G. Trolley.

Electricity and Lighthouses. — The lighthouses at present possessing installations of the arc light upon the coast of France are those of Dunkerque, Calais, Gris-nez, La Canche, La Heve, Les Baleines, and La Palmyre. A large number of lighthouses of the first order, now lighted by mineral oil, will, it is said, receive installations of the electric light at an early date.

Earthquake in Norway.—On the 1st of January a violent trembling of the earth was experienced in Central Norway, especially at Elverum and Loiten. A distinct shock was also felt on the morning of the 16th of January in the province of Christiansand. The barometer was very low at the time, but no sensible variation was observed during the continuance of the phenomenon.

Indian and Colonial Exhibition.—We understand that it has been decided to supply about 1,000 of the incandescent lamps in connection with the lighting of the forthcoming Indian and Colonial Exhibition from the Electrical Power Storage Company's accumulators. This will, we believe, be the largest number of lamps in any one building which has up to the present been supplied from storage batteries.

The Storm in the States.—The *Standard's* New York correspondent reports that the gale which swept over parts of the country recently was at the rate of eighty-four miles an hour; the greatest rate recorded of any previous gale was seventy-two miles. There was an extremely low tide on the day in question. The operations of most of the telegraph companies were stopped, many people were blown down, and there were several minor accidents.

Telegraph Clerks and Sunday Duty.—In the House of Commons last week, Mr. H. H. Fowler, answering Mr. Vincent, stated that the question of the pay of provincial telegraph clerks was carefully considered in 1881, and a scale of weekly wages was fixed so as to cover two hours work on Sunday. Applications had been received by three successive Postmasters-General for further pay on Sunday, and had been refused by each. Lord Wolverton thought it his duty to decline to reopen the question.

Australia and United States Cable.—According to the *Standard,* "Sir Alexander Stewart, ex-Premier of New

Digitized by Google

South Wales, and Mr. Randolph C. Want, of the Mackay-Bennett Commercial Cable Company, are now on their way from America with a view to arrange for the construction of a new cable between the United States and Australia." This project, which is very old, has been often discussed by men of experience, and invariably pronounced impracticable, or, at all vents, not feasible as a commercial undertaking.

POST OFFICE CLERKS.—A largely-attended meeting of the second-class clerks of the Central Telegraph Office, London, was held on Tuesday evening at the Foresters' Hall, Clerkenwell. A petition was drawn up and numerously signed for presentation to Lord Wolverton (Her Majesty's Postmaster-General), drawing attention to the fact that the petitioners have not received any benefit from the "Fawcett" scheme, formed in 1881, for the bettering of this class of public servants, and praying for an improved establishment.

EARTHQUAKE SHOCK IN ITALY.—A telegram, dated Naples, March 6, says a severe shock of earthquake occurred to-day at Marano-Marchesato, near Cosenza. Several houses fell in. One person was killed and several others injured.—A telegram from Catania announces Mount Etna to be in a state of eruption. Cinders and stones are being continually thrown up; and it is supposed that lava is coming out of the crater, but as it is covered by a dense mist no proper observations can be taken. Slight shocks of earthquake have been felt at the foot of the mountain.

THE LIVERPOOL ELECTRIC SUPPLY COMPANY.—The directors of this company, in presenting their annual report, recommend a dividend at the rate of 6 per cent. on the paid-up capital of the company. The dividends for the two previous years, 1883 and 1884, were at the rate of 5 per cent. per annum. The report states that, in addition to the contract for the whole of the electric lighting of the Liverpool International Exhibition, the company has other important orders on hand, and arrangements are in progress for a large extension of electric lighting from the company's central supply stations.

THE INDIAN TELEGRAPH DEPARTMENT.—With reference to the officers of the Indian Telegraph Department who have not hitherto shared in that advancement which is a feature of the other departments in the State, it may be noted that a recent Government resolution states that correspondence is still proceeding with the Secretary of State regarding the block of promotion in their department, and sanctions a trifling change, which slightly improves the pay of some few officers, but in no way affects the block. The result of this correspondence is anxiously awaited by the officers concerned.

ELECTRIC MUSIC.—M. Semmola, a German investigator, one of the many who have experimented in this direction, has succeeded in producing musical tones from a metal plate by electrifying it intermittently from an induction machine. The plate is supported on an ebonite funnel and is a millimetre in thickness. The terminals of the induction machine are connected to opposite sides of the plates by wires, and the path of the current is interrupted so that sparks strike across. The plate then begins to sound, and it continues to sound even if a Geissler tube or a lead wire is interposed in the break.

THE FRANKLIN INSTITUTE.—At the last meeting of the Franklin Institute the newly-elected president, Colonel Chas. H. Banes, presided, and read a paper on "The Institute in its Relations to the Progress of the Mechanic Arts in Philadelphia." The speaker called attention to the fact that from the time of its organisation the institute has done all in its power to promote the mechanical interests of the city and country. He suggested an "endowed chair of original research," and stated that, while the late Novelties Exhibition had been, from a scientific point of view, a great success, it was not so financially.

HELIOGRAPHICAL.—The silvered balls frequently seen in gardens are advocated by Mr. Hatt, in a note to the French Academy of Sciences, for heliographic purposes, in preference to plane mirrors. Their advantage lies in the greater intensity of the luminous point, which can therefore be seen to greater distances. From experiments made by him during the past summer, he found that with a sphere of a small diameter the image perceived at fifteen kilometres with a lunette had a splendour comparable to that of a star of the second magnitude in a field feebly lighted. Such an image, which can be produced at little expense, would, he thinks, be useful in topographical triangulation.

TELEGRAPHIC ADDRESSES.—The secretary of the Hull Chamber of Commerce has received from the Postmaster-General a reply to a memorial from the Chamber praying for a reduction in the amount charged for the registration of telegraphic addresses. The reduction asked for is from £1. 1s. to 5s., and the answer is to the effect that the actual cost the department incurs in respect of each registration considerably exceeds the sum of 5s., and that any balance that may remain out of the charge of one guinea is far from being sufficient to meet the loss of revenue arising out of the reduction in the number of words in telegrams which is brought about by the use of an abbreviated address.

CONDUITS FOR UNDERGROUND WIRES.—In a recent paper upon this subject Mr. R. W. Pope says:—"While it may be perfectly practicable to insulate arc light wires from the possibility of earth contact, under ground, the difficulty and expense of doing so is materially lessened by the use of an insulating conduit. Upon this question there is an honest difference of opinion between different investigators, some of whom confine their attention to the requirements of the particular branch of service in which they are interested. It being the natural tendency of electricity to seek the earth, it appears wise, if compelled to use subterranean wires, to insulate them as effectually as possible at a reasonable expense."

AN ELECTRIC GIRL!—An American exchange says:—Miss Lulu Hurst, the electric girl, who made such a sensation North and West over a year ago, is now a student in Shorter Female College, at Rome, Ga. Miss Lulu was a poor country girl, who discovered by accident that she could tumble a man out of a chair by merely touching it. She made $100,000 by displaying her power, and is going to spend some of it for an education. Dear me! We have heard of two or three poor country girls who could persuade a man to leave a chair in a remarkably short space of time with the assistance of a poker. Perhaps by "it," however, our exchange means the chair. Anyhow it is very foolish to waste hard-earnt money upon such a thing as education.

THE ELECTRIC LIGHT AND THE LARYNGOSCOPE.—A. H. Vesey, of Upper Bedford-place, W.C., has patented this instrument, in which a small incandescent electric lamp is partially imbedded in some non-conducting material, as cement, contained in a casing which is fixed by a bayonet joint within a tube lined with insulating material, to which is attached a German-silver tube of small diameter, containing the wires conveying the current. On the silver tube slides a piece carrying a rod with a mirror at one end, so that the light may be reflected as desired. At the end of the tube is an ebonite handle, containing a switch and resistance coil, so that the

Digitized by Google

strength of current may be regulated. The connecting wires project from the end of the handle, and are connected to a battery.

THE LIVERPOOL INTERNATIONAL EXHIBITION.—This Exhibition, which is to be opened in May, stands in grounds 35 acres in extent, and the buildings comprising the covered portion of the Exhibition will cover about eight acres. The contract for the whole of the electric lighting of the above has been secured by the Liverpool Electric Supply Company. Engines and boilers, capable of indicating more than 700 horse-power, will be supplied by Messrs. Marshall, Sons, and Co., of Gainsborough. 320 arc lamps and 2,000 incandescent lamps will be employed in lighting the building, the necessary dynamos being provided by the Anglo-American Brush Company. The work will be carried out under the direction of Messrs. Holmes and Vaudrey, the managing engineers of the Liverpool Company.

THE MIRROR SOUNDER.—The following suggestion was put before us a considerable time before Von Taund Szyll patented his seleno-differential recorder. Many means had been tried not only for registering the signals of the mirror instrument, but for increasing its accuracy. In the latter direction it seems to be a theoretical possibility that if two independent selenium plates were connected in two independent telephone circuits, so that the effect of the ray of light falling upon each selenium plate would cause each telephone to give out a different sound, there would be a decided gain in point of accuracy. In point of fact the mirror signals could be read by sound ; the only thing is that the light would have to be greatly intensified. The suggestion was due to Mr. Baines, formerly relieving Superintendent of the Eastern and South African Telegraph Company.

THE CITY AND GUILDS TECHNICAL INSTITUTE.—On the 4th inst., Sir F. Bramwell and a number of gentlemen interested in the management of this institution attended the Court of Common Council, and applied for a grant of money in aid of its funds. A letter from Lord Selborne was read, expressing his belief that the institute was doing a vast amount of good, and that the most satisfactory results had been obtained so far. Sir F. Bramwell replied to several pertinent questions put to him by Alderman Cotton. The total income, he said, was £29,550, and the work done was an ample return for the sums expended. The situation of the building at South Kensington was central and convenient, and everything connected with it was in a promising condition. The petition was referred to to the Coal and Corn and Finance Committee for consideration and report.

ELECTRIC LIGHT FOR THEATRES.—Grace to the good sense of managers, the use of the electric light is fast spreading in our London theatres. One of the first to adopt the gentle luminant was that presided over by Mr. R. D'Oyly Carte, the Savoy, which, without exaggeration, is the prettiest and most comfortable place of amusement in the metropolis. The installation acts splendidly, the lamps burn steadily, and are always up to their standard, while the scenic effects—more especially in connection with the gorgeous dresses in the "Mikado"—are considerably heightened by the pure and powerful incandescent. On the occasion of a recent visit we heard very hearty encomiums passed upon the lighting, and, if we add our experience to the experiences of others, it will be in unreserved commendation of a theatre whose ventilation and lighting, apart from the excellence of its performances, are without equal.

TORPEDOES.—The Edison Machine Works of New York are now, it is said, building for the United States Government a number of electrical torpedoes. These are propelled, steered, and exploded from the shore by electricity. For the purpose of steering, two powerful magnets are placed in the after part. When the torpedo is going straight ahead the rudder is held in the centre, but by the operator moving a small lever on the shore the current passes from one magnet to the other, and the rudder is put over in the required direction. A speed at the rate of over eleven miles an hour has been reached on Government tests, but it is expected that this will be exceeded. The charge consists of 400lb. of dynamite. These torpedoes, a contemporary says, have been tested by being anchored in front of a fort and kept under a concentrated fire for hours, until the float has been completely riddled, and they have yet been ready for active service.

A NEW ELECTRIC RAILWAY.—On Tuesday morning an electric railway was opened on Ryde Pier with a successful series of experimental trips, in the presence of the South-West of England Association of Gas Managers, who held their annual meeting at Ryde. The tramway, which runs down the pier, has hitherto been worked by small locomotives, but some time since the directors determined to substitute an electric railway, and entrusted the work to Messrs. Siemens and Co. The prime motor is a gas engine, which is connected by a belt to one of Siemens' dynamos, performing about 1,000 revolvtions per minute. The current is carried by cable to the conductor, which is a rod of channel iron running by the side of the tramway, and supported by brackets fitted on the sleepers and insulated. The ordinary rails, which are of steel, are used as the return current. The current is taken to a motor under under one of the cars by means of a sliding contact. Each train is worked by one of the ordinary passenger carriages, fitted with a motor, and each is capable of carrying about 13 tons. The carriages were driven up and down the railway at the rate of about 12 miles an hour.

OVERHEAD WIRES.—At the last meeting of the Wandsworth District Board of works, the General Purposes Committee having considered the letters from the clerk to the Metropolitan Board of Works, stating that a committee of such Board had been instructed to inquire into, and report upon, the subject of the fall of overhead telegraph and telephone wires during the recent snowstorm, and the expediency of measures being taken by the Legislature or otherwise to secure greater safety to the public; and asking that the surveyors might be instructed to give him information of any damage which may have been caused by the breakage of overhead wires within the area under their jurisdiction ; and from the clerks to the Vestries and District Boards, with reference to the letter from this Board on the subject of overhead telegraph and telephone wires broken during the storm; and the reports of the surveyors as to the damage done to overhead wires in the district during such storm, recommended that a copy of the surveyors' report on the subject be forwarded to the Metropolitan Board of Works. The report was adopted, and copies of the same were ordered to be sent to the Home Secretary and the President of the Local Government Board.

LIGHTNING.—A remarkable effect of lightning has been recently reported by Prof. L. Weber in a German serial. At Ribnitz, in Mecklenburg, during a violent thunderstorm, with rain and hail, about 6 a.m., the lower pane of a window on the first floor was broken by lightning, and a jet of water was thrown upwards through the aperture to the ceiling, where it detached part of the ceiling, and this, falling with the water, broke a small cigar table below. Three bucketfuls of water were afterwards taken from the room. The hole in the window was like that from a bullet, and there were radial

Digitized by Google

cracks. The path of the lightning is not very clear, but that it passed through the glass could not be doubted. Some cigars on the table, it may be mentioned, were carbonised. As to the jet of water, Prof. Weber rejects the hypothesis of a sudden generation of vapour forcing up water from the street. Another explanation offered is that the lightning, passing through the window to the street, generated a vortex of air about itself with vacuum in the interior, through which the water was driven as through a tube. A third hypothesis remains, viz., that a conical *trombe* struck the street, was reflected, and passed through the window in the form of a jet of water. In this case the lightning would merely have accompanied or preceded the *trombe*. Prof. Weber seeks further light on such phenomena.—*Nature*.

BOOKS RECEIVED.—"Precautions to be Adopted on Introducing the Electric Light. With Notes on the Prevention of Fire Risks." By Killingworth Hedges. (London: E. and F. N. Spon). There can be said to be only two classes of literature—the instructive and the amusing. The work under review belongs to neither of these classes; it is more properly contemporary with the modern catalogue put forward by any enterprising manufacturer. While purporting to be a treatise of a more or less scientific character, it is in reality but little more than a tolerably ingenious advertisement of Mr. Killingworth Hedges, and the various manufactures of the company he represents. Commencing with a few cut and dried remarks (in which electricity is spoken of as an "invisible subtle fluid") on the rudimentary principles of electric lighting, about 17 pages are devoted to the Hedges switches, the Hedges cutouts, and so forth, from which we pass on to an extensive puff of the Hedges tachometer. The rest of the work is devoted to information of an excessively elementary character, a reprint of the Phœnix Fire Office rules, a further description of the Globe switch and the Globe cut-out, together with a panegyric upon the Globe dynamo, the Globe arc lamp, the Globe lampholder, the Globe carbon, the Globe commutator, and so on; the breaks being filled up with interesting and instructive dissertations upon the Hedges safety plug, and the principles of economy as represented by a judicious purchase of the varied manufactures of Mr. Killingworth Hedges' company. As a catalogue of limited scope we have great pleasure in recommending this publication to our readers; its only drawback viewed from that standpoint is that one has to pay for it.

SUBMARINE CABLES.—Since our recent note upon the subject of the errors in the positions of submarine cables as laid down upon the charts supplied to the electricians of repairing steamers, we have received communications pointing out that in the aggregate these errors are due to the hydrographer. In some instances this may be so, but it is not an answer which can be considered in any sense as an exhaustive one. Carrying our memory back to an actual experience we can remember an instance in which a cable was broken a dozen miles or so from a terminal station. Three charts were in the possession of the electrician of the repairing steamer, and between two of these there was an hydrographical discrepancy of 2min. 30sec. On both of these, after making due allowance for this discrepancy, the cable was wrongly placed. The third chart was hydrographically correct; but there was an error in the cable position of nine miles to the eastward. Had the electrician been forced to depend upon either of these three charts the chances of a rapid repair would have been problematical. Fortunately, however, he chanced upon a fourth chart, which was not only hydrographically correct, but which also showed the true cable line. The curious part of it was that the latter was the work of an outsider, a naval officer who was acquainted with the locality, and who, accompanying the expedition, amused himself by plotting the line upon his own chart by aid of his own observations. We do not mean to accuse the submarine cable engineering staff of incompetency. There never were more competent men than those who had charge of the expedition of which we speak. We do not understand the cause of the errors of which we have spoken, but we are quite convinced that to place the whole of the responsibility upon the shoulders of the Hydrographical Department of the Admiralty is not altogether fair.

THE TELEPHONE IN NOTTINGHAM.—In Nottingham and district, under special license from the Postmaster-General and from the United Telephone Company, the National Telephone Company have the telephone service in their own hands exclusively. The service was established in May, 1881. The exchanges (local) of the company are at Bottle Lane, Basford, Long Eaton, Loughborough, Ilkeston, and a call-office has just been opened at the top of Derby-road, Nottingham. The company have now about 316 miles of wires (chiefly overhead), exclusive of 40 miles erected by them for the use of the Municipal Corporation for its communication with the police and fire brigade stations, the Castle, the Eastcroft, the University College, water and gas offices and works, and the Borough Asylum. The workhouse is also in communication with the training institution at Radford. Bottle Lane and all the subscribers are also in direct communication with Loughborough, Long Eaton, Ilkeston, Bulwell, Basford, Carlton, Kimberley, and Arnold. The latest departure is the establishment of a call office at the shop of Mr. Swinburne, watchmaker, at the top of Derby-road. This office is open to subscribers and the general public, and anyone in that locality may communicate with the residence, office, or other place of business of any of the 337 subscribers connected with Bottle Lane, the public offices departments, police and fire stations, or principal public institutions. The mode of operating is automatic and exceedingly simple. A locked box, with a slit of the size to admit a penny piece stands at one end of the counter. Beyond is an enclosed compartment, in which stands the instrument. By placing three penny pieces (a threepenny bit or two pennies and a halfpenny will not act) the circle is completed and th person put in communication with headquarters. He then mentions the name or number of the subscriber with whom he wishes to communicate, and there is a printed list alphabetically arranged at the service of the visitor. The subscriber may freely converse for three minutes, at the end of which period Bottle Lane intervenes, the circle is broken and cannot be renewed without the deposit in the slit of another magic three pence. And so on indefinitely.

ELECTRIC ARMS AND AMMUNITION.—Many attempts have from time to time been made to employ electricity in various ways in the use of military weapons. We understand that an effort is now being made to perfect and bring into practical usage a new system of firing by electricity adapted for breech-loading small arms of all descriptions as well as weapons of war of the class known as mitrailleuse. The electricity is supplied by means of a small battery in the gun, and is communicated in a simple and effective manner to the igniter in the cartridge shell. While maintaining the exterior form of the present sporting and military arms, and also the trigger, firing pin, chamber and extractor, several parts of the internal mechanism are done away with, including the main and other spring, but the same form of shell is used as in the percussion system, the electric primer being simply substituted in the place of the cap. The relatively small cost of the battery and its connections, as compared with that of the

Digitized by Google

complicated lock required in percussion, will, it is believed, result in great economy in the production of new weapons; while the alteration of the existing small arms from percussion to electric fire is easily and inexpensively made. The change in the shell for use in the electric system, by the substitution of the igniter for the percussion cap, is made at small cost, and as the igniter is not destroyed or displaced by repeated firing, it has been found to have, practically, the life of the shell. The continued improvements in the manufacture of sporting and military guns—the changes from the flint lock to the percussion cap, and from that to the central fire, seem to find their fitting climax in the electric system as now perfected in these inventions, which give the power to have within the weapon itself the source of ignition for many thousand rounds, and in the shell the medium for its use, without any change in the external form of the weapon as at present constructed. The generator or battery is simple, solid in construction, and conveniently placed in the butt of the gun. From actual experience, it is alleged, as many as 15,000 ignitions have been obtained from one battery, without any change of the elements, and extreme alternations of temperature seem to have no effect on its efficiency. An average of 5 to 7,000 is therefore considered a safe estimate of the number of shots that can be fired from an electric gun or rifle without change of battery.

THE ELECTRIC LIGHT AT LLOYD'S.—The extensive suite of rooms occupied by Lloyd's in the Royal Exchange has been successfully lighted by electricity, the installation constituting the most recent example of interior electric lighting by means of storage cells, and possessing several special features. The machinery and apparatus are placed in two large vaults in the basement of the Exchange, the current being supplied by two of Elwell-Parker four-pole, shunt-wound dynamos, each giving 200 amperes and 75 volts. These machines are driven at a speed of about 600 revolutions per minute direct from a Davey-Paxman compound semi-fixed engine of 20 horse-power nominal, but which is sometimes worked up to 45 horse-power. This plant supplies the current to about 400 Edison-Swan glow lamps, each of 10 candle-power and 50 volts. Of these lamps there are 192 in the underwriting room, 139 in the reading room, 10 in the telegram room, and fourteen in the committee and writing rooms, the remainder being placed on the staircase, in the vestibule, and in the dynamo room. The installation was completed and the lighting began towards the close of last year, and proved most successful in all respects save one. Soon after the start objection was taken by some to the noise and vibration supposed to have been caused by the engine, which, however, is very quiet and steady in running. It is said, moreover, that complaints have been made when the engine was actually not running, so that the real cause may, after all, have been the traffic in the streets. Be that as it may, all cause of complaint was removed by the introduction of storage cells, which are charged from the dynamo before and, if necessary, after business hours. The battery room adjoins the dynamo room, and in it are compactly arranged two sets of accumulators, each set being composed of 29 batteries, and each battery consisting of three cells joined in parallel, giving 180 amperes. The 29 sets of threes are joined up in series, giving 58 volts. There is therefore a total of 174 cells. They are all Electric Power and Storage Company's cells of the latest type, and the combined accumulators, when fully charged, are capable of supplying the current to the whole of the lamps for about eight hours. Between the dynamos and the batteries is an Elwell-Parker automatic cut-out, by means of which the return of the current to the dynamos is prevented should their rate of working fall below the normal speed. The conductors from the batteries to the lamps are carried in separate troughs, and safety fusible plugs are used throughout. The whole of the current is manipulated from two main distributing switch-boards which were designed by the Electric Power and Storage Company, and which afford facilities for varying the number of cells, both in the charging and discharging circuits.

THE ELECTRIC LIGHT IN COLCHESTER.—A meeting of gentlemen interested in the continuance of the electric light at Colchester took place recently at the Red Lion Hotel. Mr. J. N. Paxman was voted to the chair, and those present included Mr. Crompton and Mr. Christy, of Chelmsford. Mr. E. Thompson Smith, at the request of the Chairman, laid before the meeting the reasons which had induced him to summon it, which he did not from any personal motive, but simply because he, having been concerned in a similar previous meeting, had been asked by Mr. Christy, of Chelmsford, to call the present assembly together at rather short notice. Mr. Smith having further explained the objects of the meeting, the Chairman called on Mr. Christy, of the firm of Christy, Son, and Norris, electrical engineers, of Chelmsford, to make a statement. Mr. Christy then read a carefully-prepared statement with regard to the present plan of working, detailing all its defects, and then gave a proposed scheme for working the lighting without those disadvantages, and with several important improvements. One of the chief faults of the present arrangement was that as much as 82 per cent. of the current was lost from leakage in the mains and cells and elsewhere, owing to the high pressure, and other causes dependent on the present system. He proposed to obviate this to such an extent that the loss would be actually reduced to 10 per cent. on the whole 800 lamps, which he would propose to supply, whereas the loss of 82 per cent. was on the supply to only 300 lamps. He proposed also to work the dynamos in the evening, so that the current would go direct to the lamps, ensuring a good light as well as a constant one. Meters would be employed to check the amount of electricity supplied to consumers, and the current could with perfect ease be applied for motive power as well as lighting purposes. Mr. Christy submitted an estimate of the receipts and expenditure of the undertaking, showing that with 800 lamps a good profit might be expected, and with the increase in the number of consumers which might reasonably be expected, a still better return would result, as the working expenses would not be greatly increased. The existing plant they could buy up as it stood at a very low figure from the present company now in liquidation; and he spoke with great confidence as to the prospect if gentlemen in the town would co-operate to find the capital, leaving it to his firm to carry out the working of the affair according to the scheme he had briefly sketched out. Several of those present asked Mr. Christy various questions, to which he replied. One of these was in regard to the expense of fittings, in answer to which he said that for a shop front £1 per lamp might be considered an average. Mr. Crompton, who as a well-known and prominent electrician had been asked to attend the meeting by Mr. Paxman, stated that he had examimed Mr. Christy's scheme, and felt well satisfied with it. He thought it would work well, and though perhaps Mr. Christy had a little over-estimated the probable profit of the undertaking, he did not think he had done so to any great extent. Altogether he expressed considerable confidence in the project. Ultimately a committee was appointed, consisting of the following gentlemen, who should look into the scheme, and confer upon its practicability:—Mr. Moy, Mr. Paxman, Mr. Sanders, Mr. Wilson Marriage, and Mr. E. T. Smith.

EFFICIENCY OF THE EDISON-HOPKINSON DYNAMO.

(Continued from page 329.)

We now come to the electrical connections during these experiments. Fig. 2 shows a perspective view of the arrangement, the left-hand dynamo being that used as a motor, the right-hand one being the generator. Fig. 3 shows the connections in diagrammatic form, the thick lines being the connections between the brushes of the dynamos. C shows the generator, M the motor, F_g the field-magnet coils of the generator, F_m the coils of the motor, the current for both coming from the brushes of the generator. R is a resistance used to weaken the field-magnets of M, otherwise the counter electromotive force in M would be equal to that in G, and no current would pass from armature to armature. Upon the variation of the resistance R depends the current passing through both armatures, the higher the resistance the less the current, the lower the resistance the greater the current. From the terminals of the resistance R in the brush connections wires were led to the testing-room and the difference of E.M.F. obtained. This resistance was ·0058 ohm, so that the $\frac{\text{E.M.F.}}{\cdot 0058} = \text{C}$. Fig. 4 shows the connections in the testing room. G is a Thomson galvanometer, C a standard cell (1·453 volt). The circuit from the terminals whose difference of potential was to be measured included two sets of resistances, A D having a resistance of 2,220 ohms, and D B a variable resistance (in fact, the coils of a Post Office pattern Wheatstone bridge were used). When a suitable resistance is unplugged in D B, the galvanometer gives no deflection upon depressing the key, showing the difference of potential between A D = 1·453 volt—that is, the difference of potential between A D is equal to that of the standard cell, the two balancing each other. The difference of potential to be found is now easily obtained from the equation

$$\text{E} = \frac{1 \cdot 453\ (2220 + \text{unplugged resistance})}{2220}$$

For values of E less than 1·453 the standard cell is replaced by a secondary battery cell of known E.M.F., the above arrangement, as will be seen, not then being applicable.

With regard to the dynamometer its constant is 2·705—that is each division of the scale corresponds to a tangential pull of 2·705lb. acting at a radius equal to that of pulley + half thickness of belt.

One revolution of pulley = 3·63ft. advance of belt. Whence, if T represents tension of spring and n the revolutions of pulley per minute

$$\text{H.-P.} = \cdot 000298\, n\, \text{T}.$$

The experiments themselves can now be described :—

1. The two dynamos were run with brushes up and without the fields excited.

Scale on balance = 21·6 divisions
Revs. per min. = 808
Horse power = 5 2

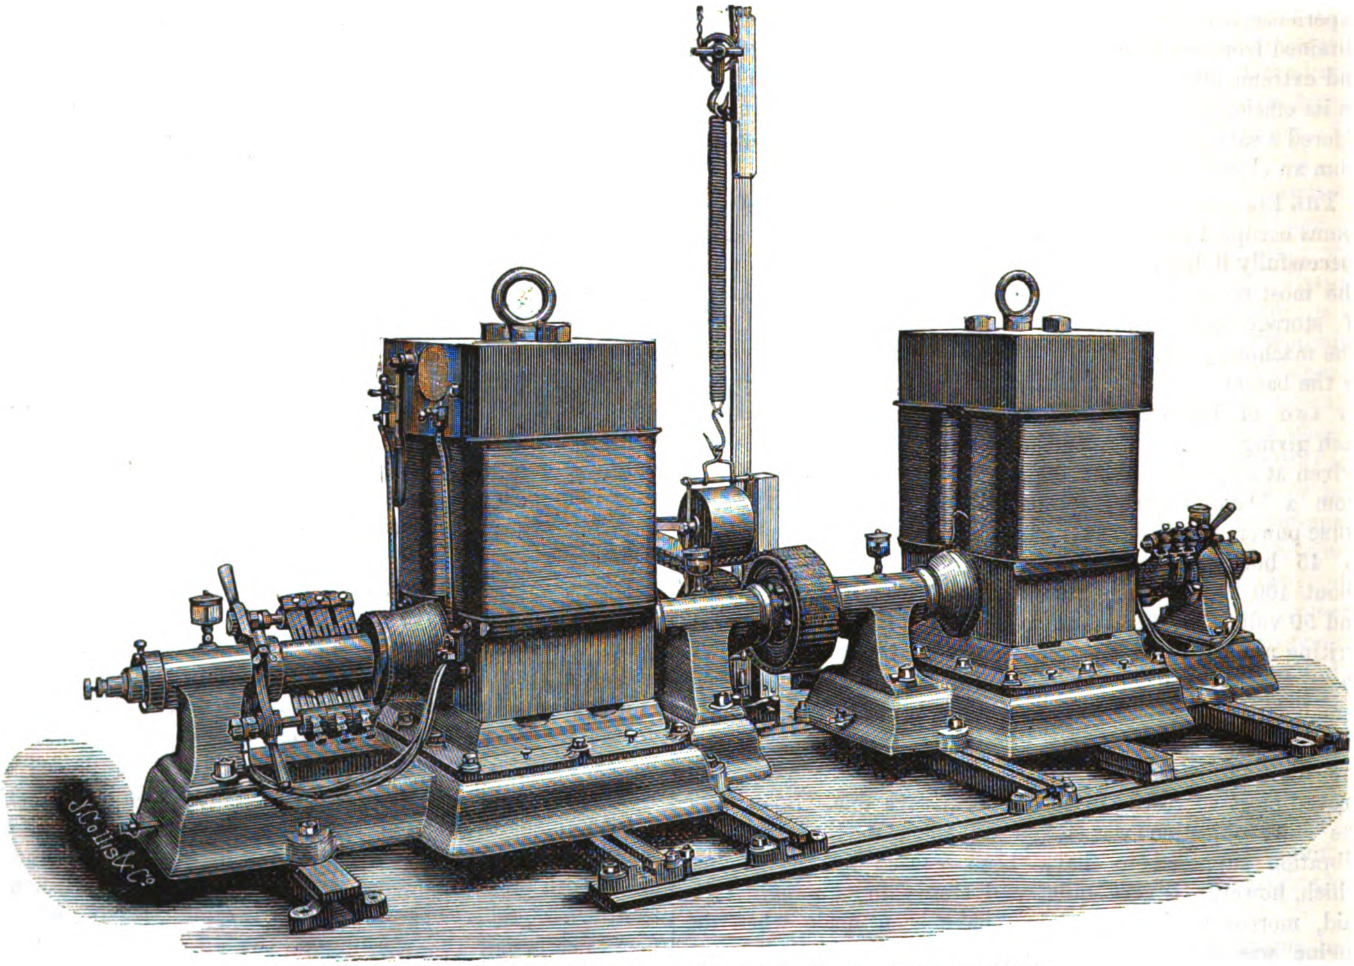

Fig. 2.—Edison-Hopkinson Dynamo, constructed by Messrs. Mather and Platt.

2. The two fields were separately excited, and the dynamos run, still with the brushes off, when

Scale = 30 divisions
Revolutions = 802
Shunt current in field of G = 6·9
" " " " M = 6·7
Horse-power = 7·169

3. The connection were made as in Fig. 3, and the following results of one of a series of similar results were obtained :—

E.M.F. at terminals of generator	=	110 12	volts.
Current	=	358	amperes.
Current through generator magnets	=	6 50	"
Current through motor magnets	=	5·36	"
E.M.F. at terminals of motor	=	107·33	volts.
Speed of machines..............	=	764	revs. per minute.
Power transmitted by belt......	=	6602	watts = 8·850 h.-p.

Digitized by Google

Hence—

Total power given o generator	= 42917	watts	= 57 53 h.-p.
Power lost in internal friction of armature core	= 831	„	= 1·11 „
Power lost in generator magnets	= 716	„	= 0 96 „
Power lost in generator armature........................	= 1360	„	= 1·823 „

And therefore—

Commmercial efficiency	= 93 23 per cent.
Loss in core	= 1·94 „
„ „ magnets	= 1·66 „
„ „ armature	= 3·17 „

Similarly for the motor—

Total power given to motor...	= 38886	watts	= 52·13 h.-p.
Power lost in internal friction of core	= 831	„	= 1·11 „
Power lost in motor magnets..	= 472	„	= 0 63 „
„ „ „ „ armature	= 1275	„	= 1·70 „

And therefore—

Commercial efficiency of motor ...	= 93·37 per cent.
Loss in core	= 2·14 „
„ „ magnets	= 1·22 „
„ „ armature	= 3·27 „

In the above experiments Lord Rayleigh's determination of the ohm and of the volt have been taken, and not the B.A. units, as in most previous experiments. The effect of this is to lower the efficiency in comparison with tests made on other dynamos, and at the same time to increase the accuracy of the results.

FIG.3

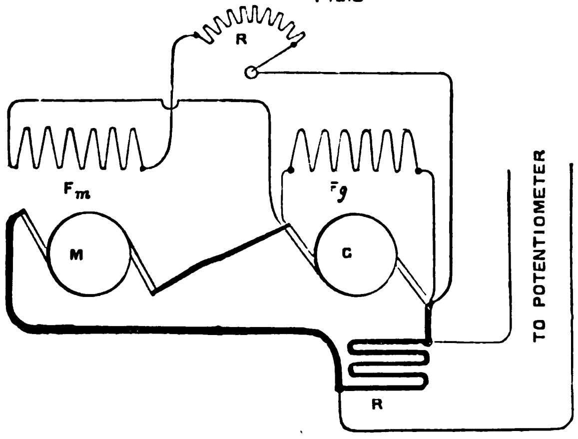

FIG.4

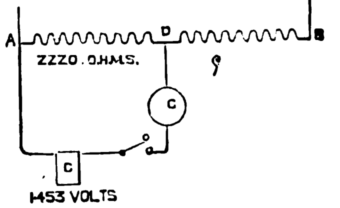

It will be seen that these figures do not take into account one or two minor losses, which tend to diminish the efficiency slightly, such as the friction of the bearings and the bending of the belt round the driving pulley. These losses depend on lubrication and the kind of belt used, so that they are somewhat variable. However, to obtain absolute accuracy the dynamos were run at their proper speed without load and the dynamometer reading noted. The driving engine was then reversed, and the dynamometer again noted. The difference in these readings is twice the friction of the two machines + twice the work done in bending the belt. The loss for one machine was found to be = ·84 horse-power when running at 800 revolutions. Taking also into consideration the variations in friction, if the belt were transmitting full power to drive one dynamo, experiment shows a loss of ·73 per cent. When these losses are deducted from the efficiency above given, the commercial efficiency is seen to be 92·5 for the generator, and 92·6 for the motor. However we look at these figures, we must acknowledge that the dynamo is one of the most efficient machines known to man, and Messrs. Mather and Platt are to be congratulated in producing a dynamo which compares so favourably with any others in the market.

We may mention, in conclusion of this article, that one of the largest Edison-Hopkinson, and probably one of the largest dynamos ever constructed, was shown to the visitors. It is designed to give an output of 50 volts, 1,000 amperes, at a speed of 350 revolutions for electro-deposition purposes.

COMMON MISTAKES IN ELECTRICITY AND MAGNETISM.

BY G. W. VON TUNZELMANN, B.SC.

III.—Voltaic Electricity.

The Electric Current.—If we consider a current of electricity flowing through a portion, A B, of a wire, there are three ways in which the phenomenon may be represented. 1. By a transference in unit time of C units of positive electricity from A to B. 2. By a transference in unit time of C units of negative electricity from B to A. 3. By a transference in unit time of P units of positive electricity from A to B, accompanied by a transference of Q units of negative electricity from B to A. As the same current is described in each case we must clearly have $P + Q = C$.

The third method, with the limitation $P = Q$, is adopted by some Continental electricians in connection with special theories as to the nature of the electric current; but for elementary purposes and for general use the first is preferable, as it is simpler, and does not commit us to any particular theory.

Comparison of Frictional and Voltaic Electricity.—The student will have learned already, in the study of frictional electricity, that electricity can neither be generated nor destroyed, but that the development of a positive electrification must always be accompanied by the development of a negative electrification of equal amount. This may be concisely expressed by saying that the amount of electricity contained in any portion of space can only be increased or diminished by the passage of electricity through the boundary of the portion of space.

Putting it in this way, we see that the motion of electricity is like that of a material fluid, an analogy which is often of great value in explaining electrical phenomena; but in making use of it the teacher should carefully guard against allowing the learner to suppose that in the electric current there really exists anything like an actual material fluid. Every material fluid has inertia, but the experimental evidence is entirely against the ascription of inertia to the electric current. We merely know that in the phenomenon known as an electric current there is motion or transference of some kind, and that whatever it is that is transferred, its transference is like that of a material fluid in that it can neither be generated nor destroyed. We do not know anything about the velocity of transference, whether it be great or small. We do not know whether there is a single transference in one direction, or a simultaneous transference in opposite directions, and, if the former, we have no means of determining which is the actual direction of the motion.

In the development of electricity, either by frictional apparatus or by a voltaic battery, the electromotive force is produced in the same way, viz., by the contact of two dissimilar substances; but in the first case the requisite energy is obtained from mechanical sources, and in the second it is obtained from chemical action.

By the use of frictional apparatus we can obtain a much greater electromotive force than by means of a battery with any practicable number of cells. Thus, Sir William Thomson deduces from experiments that he has made, that a battery of between five and six thousand Daniell cells would be required to produce an electromotive force sufficient to cause a spark to pass between metal plates one twentieth of an inch apart. On the other hand, we can obtain electricity in much larger quantity by means of a battery than by means of frictional apparatus.

Digitized by Google

If we bear these facts clearly in mind there will be no difficulty in understanding the reason for the different effects produced by electricity generated respectively by friction and by voltaic action.

In the case of students going beyond the very elementary stage, they will of course learn that by means of induction apparatus a certain quantity of electricity with small electromotive force, produced by a voltaic battery, may be made to develope a much smaller quantity of electricity with a much greater electromotive force.

In his study of frictional electricity the student will have learned that an electrical machine will not continue to develope electricity unless the conductor of the machine be put in electrical connection with the rubber, either directly or by connecting both to the same conductor, such as the earth. In order to charge a condenser, such as a Leyden jar, a break is made at some point of the circuit, and the broken ends or electrodes are connected with the two metallic coatings of the condenser. In place of an electrical machine we may use a voltaic battery, and here again it will be necessary to complete the circuit either by connecting the electrodes directly or by connecting both of them to the same conductor, say the earth, as before. The condenser may then be charged by the battery, just as it was formerly charged by the machine; but as the electromotive force produced by the battery is much smaller than that produced by the machine, the condenser cannot be charged to so high a potential as before.

I have found in my own teaching experience that students are greatly assisted in forming a clear conception of the conditions of flow of an electric current by comparing it with the flow of water through a tube. In this case electromotive force will be represented by difference of pressure, however produced, at different parts of the circuit. In the first place, for the sake of simplicity, let us consider a circuit entirely composed of conductors of electricity, so that for the present we have no condenser in the circuit. Let us fix our attention on a certain portion of the circuit, say a portion of the conducting wire, through which we wish to produce a flow of electricity. Then we know that we must introduce into some part of the circuit some apparatus, such as an electric machine or a voltaic battery, to set the electricity in motion, and to maintain its motion against the resistance of the circuit. In our hydraulic analogue the portion of wire will be represented by a piece of tube filled with water, and the whole circuit by an endless tube filled with water. To produce a circulation in such a tube we must introduce some apparatus of the nature of a pump to set the water in motion, and to maintain its motion against the resistance caused by friction against the tube, and by the viscosity of the water. A pump which can exert a great pressure, but only allows a small current of water to pass through it, will correspond to the electric machine, while a pump which can only exert a small pressure, but which drives a large body of water through it, will correspond to the voltaic battery. If we cut the tube across at some point and connect the ends with a large closed reservoir full of water we get the analogue to introducing the earth as part of the electric circuit. It is clear that the only difference that will be made in a circuit of a given length by replacing a portion of tubing by a large reservoir will be to diminish the friction, and similarly in the case of an electric circuit, as for example in the case of the circuit joining two telegraph stations, if we complete the circuit by connecting the stations to the earth instead of using a double wire the only effect (except a saving in the quantity of wire) will be to very greatly diminish the resistance of the circuit. The effect of introducing a non-conductor into the circuit may be represented by closing the tube at some point by means of a valve, kept shut by a catch, when the circulation will be stopped, unless the pump can exert sufficient pressure to force the valve open by breaking the catch, in which case there will be a flow of water through it corresponding to the disruptive discharge through a non-conductor, produced by a high electromotive force.

Action of a Condenser.—The portion of tube containing the valve may be considered to represent a Leyden jar, or other condenser, for a condenser consists simply of a non-conductor, or dielectric, as it is often called, separating two conductors.

Now, there are two ways of considering the valve and its action. (1) We may suppose that the substance of the valve itself is perfectly rigid, and that the effect of the pump is to compress the fluid on one side of it, and therefore to rarefy it on the other until the pressure becomes great enough to force the valve open. As an enormous force is required to produce a very small compression in water, we shall get a better illustration by supposing the water to be replaced by air or any gas. This compression of fluid on one side, and rarefaction on the other, gives a very good representation of the theory which supposes that positive electricity is accumulated on one coating of the condenser, and negative electricity on the other, and regards the dielectric as simply separating them.

(2) Let us now suppose that the fluid is absolutely incompressible—and here water will do very well to fix our ideas, as it is only compressible to such a small extent—and suppose also that the valve consists of an elastic membrane. Then, as the water is pumped through the tube the membrane will stretch, and if sufficient force be exerted the membrane will break, and the water will be able to pass through.

This will represent the action of a condenser according to the theory which not merely regards electrification as the action of one conductor upon another at a distance from it, but seeks to trace the action in the non-conducting medium surrounding the conductor in the form of some kind of stress produced in this medium. That is the theory of Faraday.

I have assumed the fluid to be incompressible in the second illustration, because it can be proved mathematically that if there is an electric action going on in the dielectric media surrounding conductors—and it must be so unless we admit direct action at a distance—then the flow of electricity will be like that of an incompressible fluid, so that the absolute quantity of electricity in any space can neither be increased nor diminished by any possible means.

If we replace our membrane by one which will undergo a greater extension than the first one under an equal pressure, we get an illustration of the increased charge which can be given to a condenser without increasing the electromotive force, if we replace the original dielectric by one of greater specific inductive capacity.

Development of Heat in the Circuit.—Students are usually able to write down the relation originally determined by Dr. Joule, by experiment, viz.,

$$J\,H = C^2\,R\,t,$$

where R is the resistance of a conductor, C the strength of the current through it, t the time during which the current flows, H the number of units of heat developed in the conductor, and J the dynamical equivalent of heat.

But it very frequently happens that the student's knowledge of the subject is entirely confined to the writing down of this formula from memory, and that when he is called upon to apply his knowledge to special cases he shows that he has utterly failed to grasp the simplest principles.

One of the mistakes most commonly made is to suppose that the heat developed in a circuit containing a battery may be increased by putting in additional resistance. Now assuming, as we may do with sufficient approximation for our present purpose, that the electromotive force of the battery remains constant during the experiment, and remembering Ohm's law that $E = C\,R$, where E is the electromotive force, we may write M, a constant, for C R, and our equation becomes $J\,H = M\,C\,t$, or the heat developed in a given time is simply proportional to the current. Again, suppose we wish to have a large amount of heat developed in a certain portion of the circuit. Then the relation shows us that we must make the resistance of this portion as great as possible compared with that of the rest of the circuit, while making the whole resistance of the circuit as small as possible.

For if R be the resistance of the portion considered, and H the amount of heat developed in it in time t,

And if r be the resistance of the rest of the circuit, and h the amount of heat developed in it in the same time,

Then, since the current must be the same at all parts of the circuit, supposing it to be a single circuit, we shall have

$$J\,H = C^2\,R\,t;\ J\,h = C^2\,r\,t.$$

Digitized by Google

$\therefore H : h :: R : r.$

As an example of this, consider the following question from a South Kensington paper:—

The resistances of two wires *a* and *b*, made of the same metal, are as 2 to 3. What are the relative amounts of heat developed in the wire—(1) when they are fastened end to end, and the same current passes through them; and (2) when they are arranged in "multiple arc"—that is, when each connects the ends of the same battery so that the battery current is divided between them.

Answer.—Let R be the resistance of the wire *a*, and H the amount of heat developed in it in time *t*.

Let *r* be the resistance of the wire *b*, and *h* the amount of heat developed in it in time *t*.

First Case.—Since the current is the same throughout the circuit

$$J H = C^2 R t; \; J h = C^2 r t.$$

Therefore $$\frac{H}{h} = \frac{R}{r} = \frac{2}{3}.$$

Second Case.—Let C be the current through *a*, and *c* the current through *b*.

Then we have $$C R = c r;$$

or, $$\frac{C}{c} = \frac{r}{R}.$$

The amounts of heat are now

$$J H = C^2 R t; \; J h = c^2 r t.$$

Therefore $$\frac{H}{h} = \frac{C^2 R}{c^2 r} = \frac{r}{R} = \frac{3}{2}.$$

Magnetisation by the Electric Current.—So many mistakes are made by students in answering questions on magnetisation by the electric current as to show that a large proportion of them have never formed any clear conception of the process. I have frequently seen it stated by students that an iron wire can be magnetised by allowing it to form part of an electric circuit, so that the current may traverse it from end to end. Such a statement as this could not be made by a learner who had ever formed a clear conception of what takes place.

As this is such a very common blunder, I will shortly point out the steps by which the magnetising influence of the current may be explained to the learner, using the language of Weber's theory; the teacher will easily see the modification required if he wishes to make use of the theory of magnetic fluids.

The student should first be shown that an electric current tends to set a freely suspended magnetised needle in its neighbourhood at right angles to its own direction; and he should have given to him at the same time some rule for fixing in his memory the direction in which the needle will turn, relatively to the direction of the current. Ampère's rule is probably as good as any for this purpose, viz.:—

Imagine an observer with his face to the needle to be so placed that the current enters by his feet and leaves by his head, then the north pole will turn to his left.

Now, in order to magnetise a steel or iron bar by means of the current, we place the wire carrying the current near and at right angles to the bar.

Imagine an observer with his face to the bar to be so placed that the current enters by his feet and leaves by his head; then, according to the rule just given, the effect of the current will be to turn each molecule of the bar as far as possible into a direction at right angles to the current, and with its north pole on the observer's left hand, so that the visible effect will be to make the bar a magnet, with its north pole on the left hand of the observer.

I am inclined to think that the gross mistake mentioned at the beginning of this paragraph has been partly caused by a misapprehension of the reason that iron or steel filings adhere to a conductor carrying a current of electricity, for I have even seen it stated by students in explanation of this phenomenon that a copper wire becomes a magnet as long as the current traverses it.

Of course, the real reason is that the filings are first magnetised by the current, and then attracted by it.

I would particularly urge upon teachers that when explaining the effect of an electric current, either upon a freely suspended magnetised needle or in magnetising a bar of steel or iron, the effect should first be shown of a single current passing over or under the magnetised needle or the bar to be magnetised. The learner should then have it shown to him that the effect may be increased by making the current pass in a complete circuit round the needle or bar, and still further by making the current pass through a coil wound many times round it.

If the experiment be shown only with a coil, the learner is very apt to carry away the idea that some magical power is inherent in a coil, a tendency which appears to be very prevalent with beginners, and often results in answers to examination questions which may cause considerable amusement to an examiner, but of which the consequences can scarcely be considered satisfactory either to teacher or pupil.

CORRESPONDENCE.

ELECTRO-CHEMICAL EQUIVALENTS; SELF-INDUCTION IN WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the query of your correspondent, W. K., I would say that his conjecture respecting the differences between the values of the electro-chemical equivalents is quite correct. Those in my "Dynamo-Electric Machinery" are based on the recent determinations of Lord Rayleigh and of Profs. W. and F. Kohlrausch. The one ampere current deposits, according to the latest information, 4·025 grammes of silver in one hour, or 0·001118 gramme in one second. This makes the electro-chemical equivalent of hydrogen 0·000010352, not 0·0000105 as formerly supposed. At the same time, will you allow me to point out that the figures as given in my "Dynamo-Electric Machinery" agree with those given in the 1885 edition (eighteenth thousand) of my "Elementary Lessons in Electricity." Your correspondent appears to have quoted from an earlier edition. He should see the note at the foot of page 175 respecting the different determinations.

While I am writing may I correct a slip in your report (p. 338) of the remarks I made at the last meeting of the Society of Telegraph-Engineers and Electricians? I certainly did *not* say that pinion wire or stranded wire, if made of copper or brass (or other non-magnetic metal), would possess no advantage over the ordinary round wire; on the contrary, I expressly stated that it would have less self-induction if stranded or of stellate section, but that this would not be due to the same cause that makes a stranded or stellate iron wire have less self-induction than a round iron wire. In the case of iron the advantage arises from the breaking up of the circumferential continuity, thereby diminishing the effective magnetic capacity for peripheral magnetisation by the current. In the case of non-magnetic materials this reason does not exist, and in these cases the sole advantage lies in the fact that in the stranded or stellate conductor the geometrical mean distance between the various parts of the cross-section is greater than in a round wire of equal cross-section; and, in considering the self-induction of a wire, the geometrical mean distance is all-important.—Yours, &c., S. P. THOMPSON.

Finsbury Technical College, March 7th.

CHROMIC ACID IN BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will any of your correspondents kindly help by giving me information on the use of chromic acid in batteries? How is it diluted, and are other acids added? Any information on its powers will greatly oblige.—Yours, &c.,

MIDGE.

LORD RAYLEIGH'S ELECTRIC LIGHTING ACT AMENDMENT BILL.

The Bill which has just been introduced in the House of Lords, and which we print elsewhere, for the purpose of amending the Electric Lighting Act of 1882, comes before the public under exceptionally favourable auspices. To begin with, it has the advantage of being in charge of Lord RAYLEIGH, whose reputation as a scientist will be a guarantee that the scientific details of the measure will be competently argued in the Upper Chamber and not gainsaid in the lower. Then, again, there has been ample time to consider the demerits of the original Act, and to formulate with precision the indispensable amendments now demanded. A committee of experts have been at work on the subject for a considerable time; and the Bill before us is no doubt the outcome of their deliberations. It is carefully drawn up, is clear in its provisions, and decisive as to those features of the original Act which it seeks to repeal. At the same time, while securing privileges for electric lighting identical with those conferred on gas lighting undertakings, it accepts all obligations by which the latter are bound, and in fact re-enacts the obligatory sections of the Gasworks Act of 1847 as applicable also to electric lighting works. The public mind has been prepared for this concession not less by its inherent reasonableness than by the conspicuous failure of the original Act, which was at once unreasonable and prohibitive. If the public desire the Electric Light—and we believe they do—they have had ample proof of the terms on which they cannot possibly have it, and are now definitely informed on what conditions alone they may hope to obtain it.

But the prospects of the Bill are promising from another point of view. It virtually takes the initiative. The Act of 1882 died still-born, and Lord RAYLEIGH'S Amendment Bill is to all intents and purposes the first measure on the subject that has been laid before Parliament with any sign of vitality about it. This is a greater practical advantage than may appear at first sight. If Mr. CHAMBERLAIN'S Bill had been backed with an equal weight of authority, or, better still, if it had been clothed in a garb less flaringly "red," it might have had a chance of surviving. But as nobody else offered to legislate on the subject he was entitled to offer his own terms, and to enforce them when he saw that they would be accepted rather than no terms at all. The tables are now turned. It has yet to be seen whether the Board of Trade will resume its singular attitude towards the Electric Light; but in any case it will be compelled to oppose the Amended Bill on some rational principle, if at all, and show cause why the new industry shall not be placed on the same footing as the old. The harsh conditions of the original Act have not checked monopolies, but rather tended to strengthen those already existing; instead of regulating a new industry, it has extinguished it, and the chief provision was one that cannot be defended on any but the most outrageously socialistic principles. We suspect that the Board of Trade will hesitate to avow these principles in this relation. It is one thing to make a hard bargain when a customer is at your mercy, but quite another when you have to defend yourself and lose your customer into the bargain.

It must, however, be said in fairness to the Board of Trade that the Act of 1882 was never very strenuously opposed. Many persons at that time were anxious to get an empowering Bill passed on any terms whatever, and some few, perhaps, were genuinely hopeful that it would do no great harm. Events have undeceived the latter; and as to the former, their object was sufficiently served by the sale of more concessions, which realised vast sums for the vendors, who never intended to work the system on their own responsibility. This fact, combined with the tardy discovery that the public refused fresh capital for schemes which were subject to confiscation at a not very remote date, completely discredited the electric light from a financial or business point of view. Some time must elapse, no doubt, before any marked recovery from these discouraging effects is perceived, even should the present Bill pass through both Houses unimpaired. But on the whole the delay is not without its useful side. Some people, indeed, have contended all along that the failure of the legislative experiment four years ago has been a good thing for electric lighting. It has had time to prove its vitality without parliamentary assistance; it has employed the interval in vastly improving its appliances, and perfecting its organisation, instead of expending enormous capital in undertakings essentially experimental; and, above all, it has shaken off the financial harpies who hung upon its track and made its commercial success an impossibility.

People who express these opinions—and they are men of knowledge and business capacity—are equally emphatic in their favourable predictions for the new illuminant, whenever it is allowed to start fairly under conditions which on the one hand will insure its electrical success, and on the other may promise the legitimate inventor a sure return for his capital. The lessons of the past will suffice—perhaps more than suffice—to avert any fresh outbreak of speculation where the Electric Light is concerned, very much to its advantage as a solid and lasting industry. Handicapped with extravagant prices for concessions that are meaningless and for patents that are unsustainable, no work of the kind can be undertaken with a reasonable hope of competing with gas successfully, much less of making any profit by the attempt. But

Digitized by Google

on strictly business lines it ought to succeed in doing both; and if the Act of 1882 is amended in the sense now suggested by Lord RAYLEIGH, we entertain no doubt whatever that these results will follow in due course.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As secondary batteries are now attracting the serious attention which might long since have been well bestowed upon them, consideration is naturally being given to the various devices which, under extended conditions of employment, become essential to their regulation and control.

Notice has lately been especially directed to the necessity of having at hand some simple method for arriving at their state of charge and discharge, and for automatically cutting in or out of circuit at the proper time.

I need hardly say that these are some of the several details essential to their satisfactory working to which I long since gave my attention, and as the question has now been publicly mooted it may be useful to those of your readers who are interested in the subject to be informed that one of my patents, No. 1644, 2nd April, 1883, deals specifically with these points, anticipating the ideas set forth in Mr. Parker's specification, dated 8th August, 1884, of which a full description is given in your last issue.

Certainty of action, together with the utmost simplicity, are desirable in any devices employed for such purposes, and I venture to think that nothing can be more simple, nor, as I have proved by long experiment, more reliable than the means I have described.

With reference to the space in the cell necessary for any such contrivance, an inch at one end is all that is wanted, and this is, or should be, a normal condition, there being advantages in having ample sufficiency of the electrolyte, as also room for its free circulation.

For the proper working of the arrangement described by me, due precaution must of course be taken to ensure equal diffusion of the electrolyte; but this is essential under any and all circumstances, and *must on no account be neglected.* The natural gravitation of the sulphuric acid, as it is discharged from the plates, will quickly cause a difference in density between the top and bottom of the cell, 10, 15, or even 20 degrees, bringing about other evils, such as unequal resistance in the different parts of the cell and consequent uneven work on the plates. Of the two ready methods for avoiding this, the one to be preferred is the employment of a common india rubber valve hand ball, with a tube of glass or vulcanite attached to it for plunging into the cell, with which the liquor can be quickly "blown up" twice or thrice a week—a work, say, of five minutes for every twenty cells. The other method is to overcharge every other day before stopping for two or three minutes, by which the electrolyte is agitated and to some extent mixed.

I need hardly say, however, that much or continuous over charging is to be deprecated as a minute disintegration of the peroxide plate takes place, the fine mud thus formed and deposited tending, in course of time, to bring about contacts, besides, of course, gradually lessening the amount of active material in the plate. The "blowing" process which I have always employed has further the advantage of preventing any accumulation of deposit upon the separating plugs of the plates, a result of much overcharging or of too rapid discharge.

I would observe that by adopting the above described simple method I have experienced no difficulty whatever in regulating my accumulators, and having once given my gardener instructions to charge until the acidometer has risen to a certain mark on the scale (in my case 1220°) I have had no further occasion from month's end to month's end to give any thought or attention to the matter.—Yours, &c.,

Sydenham Hall, March 8th, 1886. JOHN S. SELLON.

I enclose a copy specification, *vide* lines 7 to 30, p. 3, and 7 to 15, p. 5. No. 1644, April 2, 1883:—

My invention has for its object the effecting the cutting out of or putting into the charging circuit of secondary batteries, commonly called electrical accumulators, by means of the motion imparted to an acidometer or other equivalent instrument or appliance, such for instance as a float, or ball, or a vacuum box, which can be made to rise or fall, or be actuated in accordance with the variation in strength, density, or specific gravity (during charging or discharging), of the electrolyte or fluid employed in such batteries.

The motion thus imparted to such acidometer, float, or equivalent instrument (which may be suitably constructed either of metal or of glass or other material with metallic attachments or conductors to cause contacts), actuates mechanical or electrical devices or a combination of the same, or it may act simply by pressure upon a lever shunt valve or equivalent mechanism so that the electrical current is shunted off from or on to the cell or cells thus influenced, and by this means each cell to which such arrangement is attached, or each set or sets of cells in connection therewith which can or may be so controlled thereby, can be cut out of circuit of the charging or main circuit, and can be made to fall in again as required.

For example, one simple arrangement for attaining this end is the employment of a platinum or other suitably-constructed float, situated in or on the solution, and making or breaking contact with the rise and fall of the density of the solution. By the rise and fall of the said float or contrivance, as the density of the solution varies, contacts can be made, and by such contacts, through the medium of a relay or other device, sufficient power may be given to work a switch, or suitable mechanical or electrical contrivance, by which the main charging or the discharging current may be cut in or out as desired * * * *

My invention can be also utilised for the purpose of indicating by the rise and fall of the acidometer, float, or instrument the condition of the batteries at any time—that is to say, either the extent to which they have been charged or the amount of electrical energy remaining in them.

My invention can also be utilised for indicating and registering the amount of current put in or taken out of the cells or batteries, each contact made by the rise and fall of the float or instrument at the time of charging or discharging, actuating by mechanism a ratchet wheel or other suitable device which sets in motion the necessary mechanism.

SECONDARY BATTERY INDICATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You very justly remark in the last edition of *The Electrician* that "the economical advantage of employing secondary batteries is obvious, notwithstanding the first loss of energy," but to say "that until recently the attempts to employ them in distributing stored electrical energy over wide areas have wholly or partially failed for want of an indicator to inform us of the condition of the cells" is scarcely the case.

It would appear from remarks lately published on the subject that the existence of a practically perfect guide as to the condition of cells, and as an indicator and current manipulator, has not been generally known.

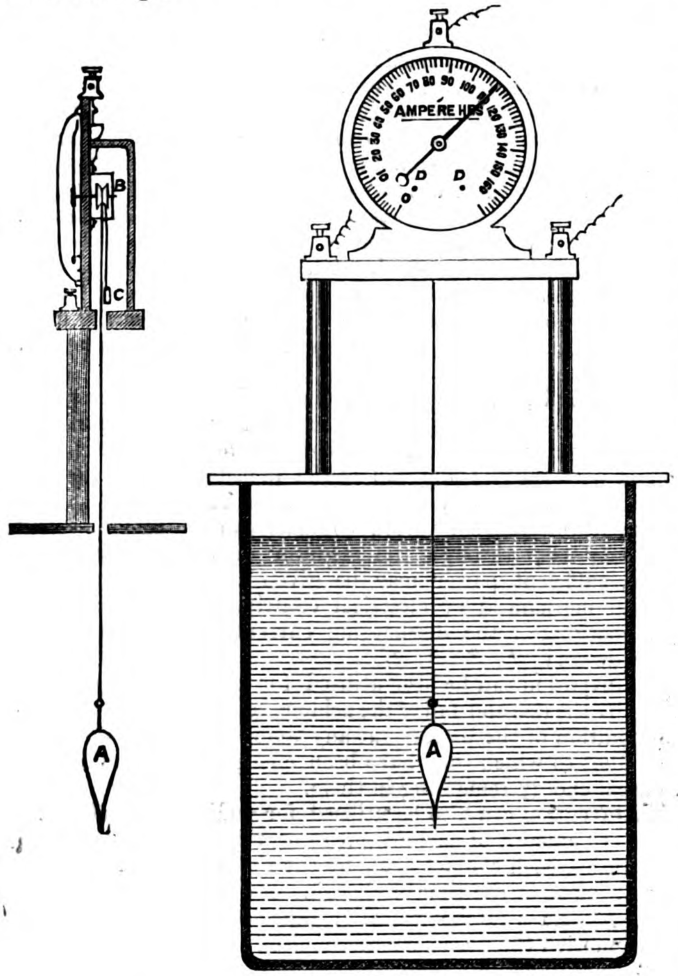
Now that the working of secondary batteries is beginning to be better understood, the necessity of a reliable indicator and current manipulator is recognised, not only for isolated installations in order to prolong the life of the plates, but also in distributing stored electrical energy over wide areas.

Having had some experience with an arrangement which depends upon the rise and fall of the specific gravity of the electrolyte, I enclose rough sketches of same, as I feel sure it would interest many to know what has been done in this direction.

Figs. 1 and 2 illustrate an indicator which is very useful for showing condition and quantity of current put into or taken out of cells. A is a platinum or glass bulb or float, which is in the cell. Attached to this is a fine wire of glass, or of platinum, to which is joined a silk thread; this silk thread passes over wheel B, ending with a cup or weight, C, adjusted to the desired weight. This arrangement is similar to the action of a wheel barometer.

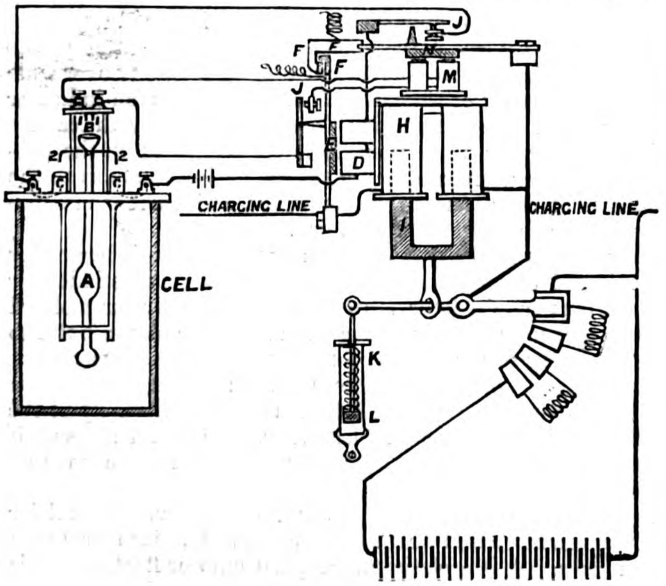
Digitized by Google

Under ordinary conditions of working, 10 degrees of density may be taken as representing 100 ampere hours, which gives considerable motion to the bulb or float. It is obvious that the wheel B can be made of such a size as to give large or small readings.



Figs. 1 and 2.

Figs. 3 and 4 show an automatic current manipulator or charging switch, wherby any number of sets of cells may be brought in or cut out of the charging circuit, through the



Figs. 3 and 4.

rise and fall of the density of the electrolyte. A is an acidometer hydrometer, the motion up and down of which causes wires 1 and 2 to make contact with the mercury in cups B and C C.

It will be seen by the sketch that on the fall of the acidometer through the discharge of the cell contact is made by wire 2 2 with mercury cups C C; this connects up one or two cells with magnet D. This magnet, by attracting its keeper, E, opens the circuit at F F F; this causes the charging current, if acting, to pass through the wire of solenoid H, which, by attracting its core, I, switches in resistance, short circuits same, and finally connects up the cells with the charging main. Contact springs J J break the connection of magnets D and M, opening the one which has operated, closing the other ready for the next operation. This prevents waste of current which would take place, as the contacts at 1 and B and 2 and C remain closed until an alteration of the specific gravity occurs.

The opposite action takes place on completion of charging contacts being made at wires 1 1 with mercury cup B. This actuates magnet M, which by attracting its keeper, N, causes the end of the keeper E to spring in and lock at F F F, thereby short-circuiting solenoid H, which releases its core, I, spring K in dash pot L, switching in resistance, connecting up, and thereby disconnecting the set of cells from the charging main.

It will be seen that by such an arrangement sets of accumulators can be readily and surely switched in and out of the charging circuit at any desired point of charge or discharge. The above arrangements are the invention of Mr. Sellon, patents for which were taken out by him in April, 1883, or nearly three years since.—Yours, &c.,

March 8, 1886. Henry A. Kent.

RE REGULATION OF SECONDARY GENERATORS IN PARALLEL.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In Prof. Forbes's recent lecture on "Electrical Distribution" he raises the point, that secondary generators placed in parallel will not work practically, on account of the rise of E.M.F. when some of the generators are turned off. This does not appear to be correct; at least, as you will see from the example below, the rise of E.M.F. is very small.

Take a difference of potential of 2,000 volts between the mains.

Say the resistance of the mains is ·582 of an ohm per mile, and that a 20 candle-power lamp takes 60 watts.

Then the current for a generator to supply 100 lamps = 3 amperes (neglecting loss in conversion).

< ¼ mile >		< ¼ mile >		< ¼ mile >	
Source ½ mile R = ·291ω	A	1 mile R = ·582ω	B	1½ mile R = ·873ω	C

The generators (100 light) "A," "B," and "C" are placed ¼, ½, and ¾ of a mile respectively away from the source of current. The current at A = 9 amperes, E.M.F. lost in mains = ·291 × 9 = 2·619 volts, or instead of 2,000 volts you get 1997·3 volts.

In a similar way at "B" you get 1993·9 volts, and at "C" you get 1991·2 volts, instead of 2,000. Now cut out "A" and "B." The E.M.F. at "C" will now be 1997·3 volts, or a rise per cent. of about ·3 volt.

I should be glad to know if any of your readers have from experiment found that this rise is sufficient to materially affect the lamps.—Yours, &c., Reginald J. Jones.

2, Lady Somerset-road, N.W., March 10, 1886.

SHUNTS AND SENSIBILITY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: A little while ago, when examining a cell for slight variations in the current under certain influences, I was led to ask what degree the galvanometer should be adjusted to, by shunting, &c., so as to be most sensitive for indicating any increment or decrement in the principal current. Anybody

Digitized by Google

knows that a tangent galvanometer at a low deflection will rise 1° for a smaller addition of current than when at a high deflection, where, for instance, doubling a 70° current gives only 10° more deflection. Thus, although in one sense shunting a galvanometer diminishes its sensibility, there is at the same time a gain in sensibility in so far as the needle takes up its permanent position at a lower degree of the arc. Does it, then, pay on the whole to shunt the galvanometer or not?

My own finding is that there should be a maximum sensibility of indication upon the arc when the needle, either by shunting or for an opposite purpose by using additional turns in the coil, is adjusted to 45°. As, however, I am myself a clumsy mathematician, I should desire a correction or confirmation of this result; and the natural prominence of the question assures me that one or other of your mathematical contributors has probably dealt with it already. If so, I should feel indebted for a reference to the place.—Yours, &c.,

37, Burlington-road, W. E. ALDRED WILLIAMS.
March 6th, 1886.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the letter under the above heading which you published last week, Prof. Silvanus P. Thompson says that I was wrong in stating that 736 watts correspond to one horse-power, and that Lord Rayleigh's recent determination of the ohm and volt has nothing to do with that figure. With regard to the first objection I cry at once peccavi, because I failed to notice that Prof. Thompson bases his calculation on the English horse-power, whereas I had in mind the French horse-power of 75 kilogramme-metres per second. The latter is equivalent to 736 watts, the former to 746 watts. I cannot, however, agree with him in his remark that Lord Rayleigh's determination has nothing to do with this figure. We cannot measure volts or amperes without instruments, and as long as it was doubtful whether the instruments were calibrated to true volts and amperes the knowledge that 736 or 746 watts represent theoretically one horse-power had no practical value. It was only after Lord Rayleigh had actually enabled us to obtain correct calibrations that these figures could be accepted as substantially correct, and could be used in calculations of power and efficiency. Prof. Thompson offers another correction to the review of his book, and this is of a very important character. I refer to his remarks about critical speed. After suggesting that I am not aware of the proper use of the term critical speed, he explains that he uses the term as representing that speed at which the characteristic curve of the machine runs approximately parallel to the line that represents (by the tangent of its slope) the armature resistance. I am at a loss to understand this. How can a curve be approximately parallel to a straight line? Surely your correspondent must have had in mind a particular portion of the characteristic only, and, be it understood, a portion so short that it can be considered as straight. Now, the question arises, what portion? The origin, the middle, or a point far out? I cannot pretend to be able to interpret Prof. Thompson's meaning, and must leave it to him to explain the approximate parallelism between a curve and a straight line, but I am prepared to show that under no possible circumstances can any portion of the characteristic of a separately-excited dynamo (or of a magneto machine) be even approximately parallel to the line which by the tangent of its slope represents the armature resistance. Say we plot the currents from left to right as abscissæ, and the electromotive forces at the brushes of the armature we plot as ordinates. The curve thus obtained is the external characteristic of the separately excited machine, and the internal characteristic we obtain by adding the loss of E.M.F. occasioned by the resistance of the armature. Now, theoretically, the internal characteristic ought to be a straight line drawn at a certain height (which depends, amongst other things, on the speed) above and parallel with the axis of abscissæ. In reality the line is not straight, but has a certain downward tendency which is due to the effect of self-induction in the armature wires. On the other hand, the line representing the resistance of the armature has an upward slope, and I should like to know by what stretch of imagination anyone can consider the two lines as approximately parallel. But this is not all. Prof. Thompson tells us that there is one particular speed at which the approximate parallelism occurs. Are we to understand that by suitably varying the speed we can change the downward slope of either the internal or the external characteristic into an upward slope? By increasing the speed we may raise the curves bodily, but we cannot make them less drooping. In all probability they will become more so, because the effect of self-induction increases with the speed.

Prof. Thompson's definition of critical speed is only applicable to a series machine, and then it must be thus modified:—The critical speed is that speed at which the portion near the origin of the internal characteristic curve approximately coincides with the line that represents (by the tangent of its slope) the total resistance in circuit. A similar definition could be given for shunt machines, but in that case the characteristic is not the curve representing external current and E.M.F.; it is the curve representing shunt current and E.M.F., and therefore virtually that of a series machine.

I am glad Prof. Thompson understands my meaning of the term critical speed. He says: "If the sense in which the writer of your notice uses the term were correct, then no magneto machine or separately excited dynamos could have a critical speed." This is precisely what I do mean. Only self-exciting dynamos have a critical speed, and since motors are excited from an external source, they have no critical speed.

In this matter I wish for nothing better than to be convinced of the contrary, for in that case the problem of self-regulating motors worked in series by a constant current could be solved in a very simple way, and an immense step would be made in the development of an economical system of distributing electricity over large areas. If my views on critical speed be right, special, and probably complicated, regulating apparatus will have to be added to each motor. If Prof. Thompson be right, then all is easy and plain sailing; and I trust he will further address you on the subject, although the etiquette of journalism forces me to remain without name.—Yours, &c.,

THE WRITER OF THE REVIEW.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read Dr. Stone's letter in your previous number, and have to remark thereon that all the satirical writing which he or others may produce will never deter me from publishing that which I know to be facts regarding electrical phenomena, no matter how slow other men are in adopting my views about electricity. For example, the following paragraph is now going the round of the journals, as if it contained something new:—"Prof. Clausius says that in order to explain the propagation of luminous waves across space it is requisite to admit the existence of a matter susceptible of more subtle division than the ponderable gases; this is the matter to which at present the name ether has been given; Prof. Clausius deems it no other than electricity." It is gratifying to me that Prof. Clausius has now given his adhesion to the foregoing, which was published in my "Theory of Electricity" in the year 1839, copies of which were at that time sent to Faraday, Arrago, and other electricians.

Dr. Stone makes merry about there being two Electric Boys. I therefore state that there is a man in Edinburgh who has made himself obnoxious to others by his utter want of principle, and who, I have been informed, got up an exhibition of an electrical boy after the genuine electrical boy had been exhibited. When I wrote my last letter to you I thought it right to allude to the second and fallacious electrical boy, lest it had been this boy that your correspondent had seen, as I then gave "Hamlet" the benefit of supposing that he was a truthful writer; but his last letter to you has opened my eyes on this point, and I presume those of your readers. In order to be able to test the truth or falsity of the contents of "Hamlet's" note to you (p. 214), I put to him these questions.

Digitized by Google

1st. What kind of electrical apparatus was used? 2nd. How was the electricity conveyed to the boy's body?

Instead of answering these questions, "Hamlet" writes:— "My note, p. 214, sufficiently answers Nos. 1 and 2 questions." Now, this is incorrect, for the note contains no answer of any kind whatever to the questions. It is now manifest that "Hamlet" saw neither of the boys, and that his note to you (p. 214) is entirely a fabrication out of his own brain. When one can do such a deed as this under the shelter of an anonymous name his opinion on any subject is unworthy of notice, and can bear no weight with those who love the truth.

Other engagements prevent me at present, but I hope to continue in your columns (if you will allow me) the subject of air in the lungs being the source of electricity in the human body. In the meantime, let me direct your readers' attention to the new discovery in Germany about the coagulation of blood. Formerly, scientists could keep blood from coagulating for only a quarter of an hour; but now it can be kept from coagulating for days, and this independently of the question of temperature, the blood not being required to be kept at the temperature it was at when it came out of the living subject. If the blood be received in vessels lined with oil, or vaseline, or grease, and be covered up with either of these substances it will not coagulate for days, but if any sharp point of foreign matter comes in contact with the blood in these vessels coagulation will begin at once at that point, and extend from it to the whole of the blood. For a century electricians have disputed about the effects produced by the contact of solids, but now we have added phenomena concerning the contact of blood which the Germans have not referred to electrical action; but I believe it is electrical. The oil, vaseline, and grease are non-conductors of electricity, and points are the very best conductors of electricity; hence the difference of their action on the blood. The new-drawn blood contains a certain amount of latent electricity, which, when abstracted, permits the blood to coagulate.—Yours, &c., JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, 8th March, 1886.

[We must now close the correspondence on this subject.—ED. *E.*]

ECONOMY IN ELECTRICAL CONDUCTORS.*

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

I. At the meeting of the British Association in 1881 a most valuable solution of a very important problem was given by Sir William Thomson regarding the proper sectional area to give to a copper conductor used in transmitting electric energy. In the account of his communication given in the Report of the British Association for that year it is stated that "he remarked that (contrary to a very prevalent impression and belief) the gauge to be chosen for the conductor does not depend on the length of it through which the energy is to be transmitted. It depends solely on the strength of the current to be used, supposing the cost of the metal and of a unit of energy to be determined." And he concluded that for twelve hours per day work "the sectional area of the wire in centimetres ought to be about a fiftieth of the strength of the current in webers."

It is, of course, well known that this rule has to be departed from when considerations have to be taken into account other than that of obtaining maximum economy; for example, the necessity in any general system of electric lighting of maintaining the potential difference along the mains constant within certain limits may lead us to adopt a thicker conductor than is given by the rule of one square centimetre per fifty amperes; while, on the other hand, our desire to obtain a large magnetic effect in an electromagnet, or a large electromotive force in a dynamo, induces us to employ a much thinner conductor than the rule indicates. But, at any rate, when the cost of copper and the cost of coal are the leading considerations, it might appear that Thomson's rule ought to be rigidly adhered to, proper allowance being, of course, made in any particular case for the number of hours of working, the cost per ton of copper, the annual rate of interest and depreciation, and the annual cost of an electric horse-power. Indeed, this is the view that we, and possibly other electrical engineers, have taken, and it was not until comparatively recently, when engaged in actual calculations regarding the proper dimensions to give to the conductors in telpher lines, that we recognised that Thomson's solution of the most economical section to give to a conductor was quite inapplicable in a variety of cases connected with electric transmission of power.

II. Let us consider a little more in detail the solution that Thomson gave. He arrived at an expression for the total waste per mile in a conductor arising from the generation of heat and interest on copper which we find convenient to put in the following form:—

$$C^2r + \frac{t^2}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Where C is the current in amperes, r the resistance of the conductor per mile in ohms, and t a constant which depends on the annual interest on the value of a ton of copper, allowing for depreciation, and the annual cost of an electric horse-power for the number of hours per year that power is required. Our expression (1) is, in fact, the *total* rate of waste per mile *reckoned in watts.**

In order that this may be a minimum for a given value of C

$$C = \frac{t}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

If we take £15 as the annual interest (allowing for depreciation) per ton of copper—that is to say, about 12 per cent. on £125, which is a fair estimate for a ton of good conductivity copper, allowing for the value of the necessary amount of insulation; and if we take £15 also as the annual cost of an *electric* horse-power for the number of hours per year that power is required, it is easy to show that

$$t^2 = 297{\cdot}3$$

so that (2) reduces itself to

$$C = \frac{17{\cdot}24}{r}$$

$$= \frac{17}{r} \text{ approximately} \quad . \quad (3)$$

corresponding with about 60 amperes per square centimetre, or 393 amperes per square inch.

Now, supposing that we desire to apply this result to such a case as the following, which will frequently be met with in electric lighting and transmission of power:—What size of copper conductor ought to be employed when a certain amount of power, P watts, has to be furnished at the end of a conductor n miles long, and when the highest potential difference we are allowed to use from considerations of safety, or it may be that is allowed us by the Board of Trade, is V volts?

Let C be the current in amperes, then, since the maximum potential difference must be at the near, or dynamo, end of the line, the potential difference at the farther end will be

$$V - Cnr$$

if r is the resistance per mile of the conductor in ohms, and if the earth be used as the return, or if r is the resistance per mile of the going and return conductor.

$$\therefore P = C(V - Cnr) \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and by Thomson's rule

$$C = \frac{t}{r},$$

hence we have two equations from which to determine C and r. The values of C and r so obtained are

$$C = \frac{P}{V - nt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

* Paper read at the Meeting of the Society of Telegraph-Engineers and Electricians, March 12th.

* Although it would not avail bankers to reckon that a business which cleared £1,500 a year produced so many watts, yet such a mode of reckoning is very convenient in problems like the one under consideration. With an electric horse-power costing £15 per annum, the business clearing £1,500 annually might be regarded as producing 74,600 watts, and 5 per cent. per annum interest on £120 might be regarded as an income of 298·4 watts.

Digitized by Google

and $$r = \frac{t(V - nt)}{P} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

and these are the values of C and r that it might appear ought to be selected in order to obtain maximum economy.

As an example, let

$$P = 10{,}000 \text{ watts},$$
$$V = 200 \text{ volts},$$
$$n = 10 \text{ miles},$$
$$t = 17,$$

then from (5) and (6)

$$C = 333 \text{ amperes},$$

and $$r = 0{\cdot}051 \text{ ohm}.$$

But it is easy to see from (4) that with an initial potential difference of 200 volts, the same power, 10,000 watts, can be delivered at the end of 10 miles of a conductor having the same resistance per mile if, instead of using 333 amperes, we use only 59 amperes, and as the loss of power in heating is proportional to the square of the current, the waste in heating when using the smaller current will be only about the twenty-sixth part of what it would be if we used the current given us by equation (5).

In fact, for each value of r there are two solutions of C which satisfy (4), whereas only one of them can satisfy (2). In this example, then, *twenty-six times as much economy in coal will be obtained by neglecting Thomson's rule as by following it.*

III. Now, what is the explanation of this? The cause cannot, of course, be due to any error in Thomson's reasoning, and it arises from the fact that Thomson's solution gives the minimum value of the expression

$$C^2 r + \frac{t^2}{r}$$

only when C is regarded as a constant, and r as the *sole* variable. But if, as in the present case, both C and r in this expression are variables connected by some equation such as

$$f(C, r) = 0$$

then the equation connecting C and r which makes the total waste a minimum is *not*

$$C = \frac{t}{r}.$$

In fact, when the maximum difference of potentials V is fixed, the current C can only be regarded as a constant when the power *put into the line at the dynamo end*, VC, is given, and when the amount delivered at the other end is, so to say, left to chance. Under these conditions, Sir William Thomson has given us a most useful rule for determining the size to give to the conductor to obtain maximum economy, but his solution can only be used when the value of the current is previously known.

But since, in many practical cases, it is the amount of power that has to be furnished at the distant end of the line that is fixed for us by the contract, C must not be regarded as a constant, and a totally different method must be adopted to obtain the size of conductor to be employed, so that the waste of power in heating the conductor, together with the interest on the value of the copper, may be a minimum. For not merely, as we have shown, does the current of 333 amperes and a resistance of 0·051 ohm per mile, as determined from (5) and (6), lead to twenty-six times as much waste in heating as will be produced by using the equally effective current of 59 amperes with the same conductor, but as we shall show there is a solution of the problem even more economical than this.

IV. If we write $F(C, r)$ for the total waste which is

$$C^2 r + \frac{t^2}{r}$$

and if our supply condition connecting C and r is

$$f(C, r) = 0,$$

then the equation which gives us the minimum of $F(C, r)$ is

$$\frac{dF}{dC} \times \frac{df}{dr} - \frac{dF}{dr} \times \frac{df}{dC} = 0.$$

Hence performing the partial differentiations on our two functions (1) and (4) we have

$$2Cr \times C^2 n - \left(C^2 - \frac{t^2}{r^2}\right)\left(2Cnr - V\right) = 0 \quad . \quad . \quad (7)$$

Eliminating r from (4) and (7) we obtain

$$C^2 - 2C\frac{P}{V} + \frac{P^2}{V^2 + n^2 t^2} = 0 \quad . \quad . \quad . \quad (8)$$

$$\therefore C = \frac{P}{V}\left(1 \pm nt\sqrt{\frac{1}{V^2 + n^2 t^2}}\right),$$

and, as CV, which is the power put in at the dynamo end of the line, must necessarily be greater than P, the power given out at the distant end, it follows that the plus sign is alone admissable. Hence the current that must be used to obtain maximum economy is

$$\frac{P}{V}\left(1 + nt\sqrt{\frac{1}{V^2 + n^2 t^2}}\right) \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Substituting the values employed in the previous example for P, V, n and t, we find that the current that gives maximum economy is

82 amperes,

and from (4)

$$r = \frac{CV - P}{C^2 n} \quad . \quad . \quad . \quad . \quad . \quad . \quad (10),$$

so that the resistance per mile that gives maximum economy is

0·0954 ohm, and not 0·051 ohm.

We may now use the three sets of values of C and r that we have obtained in connection with our example, and find what values they give to the expression

$$C^2 r + \frac{t^2}{r}$$

which represents the total rate of waste reckoned in watts due to the production of heat on the conductor, and to the interest, including depreciation, on the value of the conductor.

A. Using the values of C and r given by (5) and (6), obtained from combining Thomson's condition of maximum economy with the condition of electrical supply, we have for the above expression

$$333^2 \times 0{\cdot}051 + \frac{289}{0{\cdot}051} = 5654 + 5666$$
$$= 11320 \text{ watts}.$$

B. Using the value of r given by (6), and the second value of C given by (4), we have for the above expression

$$59^2 \times 0{\cdot}051 + \frac{289}{0{\cdot}051} = 177 + 5666$$
$$= 5843 \text{ watts}.$$

C. Using the values of C and r given by (9) and (10), the proper equations to be used for obtaining maximum economy, we have for the total waste

$$82^2 \times 0{\cdot}0954 + \frac{289}{0{\cdot}0954} = 641 + 3030$$
$$= 3671 \text{ watts}.$$

Although, then, the current of 82 amperes and the resistance of 0·0954 ohm per mile leads to a greater waste in heating than the current of 59 amperes and the resistance of 0·051 ohm per mile, yet the former are the most economical to employ. In fact it will be found that a conductor having a resistance per mile either greater or less than 0·0954 ohm leads in our example to greater waste than is produced by employing this conductor.

(To be continued.)

DYNAMO TESTS.

(Continued from page 337.)

On looking at the table, it will be seen that the efficiencies for the two tests differ by about one per cent. The agreement of the measurements of the current and potentials as shown in the values of the resistances, calculated from them, is very good. Whether the difference is due to the power measure-

* Unofficial.

ments, or to different conditions of lubrication, velocity, &c., is impossible to say.

After the second test the insulation of the armature gave way, making it impossible to repeat the full load measurements, or to test on the partial loads.

EDISON NO. 10 DYNAMO.

Diameter of armature...	$9\frac{11}{16}$in. inside; $10\frac{5}{8}$in. outside.
Weight of machine	4710 pounds.
Number of commutator bars	64
Turns of wire in a coil	1
Length of useful wire in a coil	33in.
Must brushes be adjusted ?	Yes.
Diameter of bearing	$2\frac{3}{8}$in.
Length of bearing	$9\frac{5}{8}$in.
Number turns per minute	1200
Volts for best work	125
Amperes for best work	200

Table II. gives the results of the measurements :—

There is little to say of the full load measurements of this machine. The extreme difference is about one-half per cent ; the greatest difference from the mean one-fourth per cent.

The dynamo was measured twice on the partial loads. The first set was on the same day as the full load tests, the machine being run on open circuit for a couple of hours after the last full load measurement, then tested for quarter load, then run on half load for a while and tested, &c. The second set, made some days later, showed that the machine had not been sufficiently cooled for the first set of measurements. The total efficiencies, calculated from the two sets of measurements, differ for the quarter load about one and one-half per cent. ; for the half load, three-quarter per cent., and for the three-quarter load, one-seventh per cent.

In comparing these total efficiencies, if the difference of armature friction (·152 horse-power) be applied to the first set, we get

	$\frac{1}{4}$ load.	$\frac{1}{2}$ load.	$\frac{3}{4}$ load.
First set	83·10	90·51	92·83
Second set	83·32	90·55	92·44

But as the measurement of friction was made after the three-quarter load in each case, the values for this load should agree better than for the others. Part of the difference of ·39 per cent. is undoubtedly due to the fact that in the last set of measurements the unsteadiness of the potential galvanometer

Digitized by Google

while measuring the armature resistance, due to changes in the contact resistance of the brushes, was so great that the brushes were held against the commutator, thus giving too small a value of r_a, and therefore of $E/_t$. On the whole, the agreement of the two sets is very satisfactory.

WESTON NO. 7 M. DYNAMO.

Diameter of armature	9¾in.
Weight of machine	3,300
Number of commutator bars	64
Total number of turns in coils	128
Turns per commutator segment	2
Average length of a turn	6ft. 8in.
Must brushes be adjusted?	slightly.
Diameter of bearing, pulley end	2in.
Diameter of bearing, commutator end	1½in.
Length of bearing, pulley end	7½in.
Length of bearing, commutator end	6½in.
Number of turns per minute	1,050
Volts for best work	160
Amperes for best work	125

Table III. gives the results of the measurements:—

As stated under "potential measurements," there was a sharp change in the value of the constant of the potential galvanometer between the second and third tests. The following are the calibrations made:—

Time.	Value of K_{50}.	Method.
A.M.	at 25 degrees.	
10·00	1·305	Voltameter with standard resistance.
11·35	1·307	Current galvanometer with German-silver strips.
P.M.		
12·50	1·308	Current galvanometer with German-silver strips.
2·50	1·287	Current galvanometer with German-silver strips.
3·05	1·286	Voltameter with standard resistance.
4·15	1·286	Voltameter with standard resistance.

For the first two tests, the value 1·306 was used; for the last two, 1·286.

(To be Continued.)

LIGHTHOUSE ILLUMINANTS.

On Wednesday evening, at a meeting of the Society of Arts, held at their house in John-street, Adelphi, a paper on "The Experiments with Lighthouse Illuminants at the South Foreland," was read by Mr. E. Price Edwards, who pointed out that the only illuminating agents that had successfully born the tests of experiments and experience were oil, gas, and electricity. They were the only three sources of light upon which complete dependence might be placed. Electricity had been employed in this country with success since 1862, and its limited use was due rather to a dislike on the part of mariners to its extremely dazzling light when they were close to it than from any practical difficulties in its installation. As to the machines used for its generation, some trials were made in 1876, and the verdict then was in favour of Siemens's dynamo machines, and accordingly they were adopted at the Lizard in 1877. In consequence, however, of some serious irregularities in these machines, one of Baron de Meritens's new generators was tried at the Lizard, where it had worked satisfactorily for several years. During the trials at South Foreland the machines were worked either singly or coupled up with two machines in series, and occasionally with three machines in quantity. The lights shone were produced by either one machine, with an average current of 125 amperes, and E.M.F. of 51 volts; two machines in quantity for one arc light, with an average current of 176 amperes, and E.M.F. of 60 volts; two machines in series for one arc light, with an average current of 182 amperes, and E.M.F. of 60 volts; three machines in quantity for one arc light, with an average current of 180 amperes, and E.M.F. of 60 volts. It would be seen that the most effective results were obtained with two machines coupled in series feeding one arc light. As to the arrangements for the electric light, the regulation and control of the arc light produced between two carbon terminals were mainly dependent upon the action of the lamp or regulator, the delicate and ingenious mechanism of which kept the carbon points as nearly as possible the same distance apart. The carbons which gave the best results in the trials were the Berlin core carbons, supplied by Messrs. Siemens, 40 mm. in diameter, and with a core of graphite running through the centre. With alternating currents the electric arc could generally be maintained with a fair amount of steadiness with carbons that were tolerably homogeneous in their composition. The Berlin carbons, with their graphite core, were found to burn with exceptional steadiness, possibly because the centre core afforded the current an easier and consequently more regular course. As to the results of the experiments, it was found at a comparatively early stage of the trials that no practical advantage was gained by superposing electric lights, but that a sufficiently effective result was obtained from one arc fed by two electric machines. This form of light was accepted by the committee as that best suited for the exposition of the electric system, and that upon which it should be judged in respect of its merits as a lighthouse illuminant. In stating the results of the trials, it would be sufficient to regard each light as shown in its highest power—viz., electric, one light, two machines; gas, four lights, 108 jets; oil, three lights, six wicks. In fine weather it was evident that all the lights were too good, and that no one was really better than another; in fact the lower powers of any one of the illuminants would be sufficiently serviceable for the requirements of the mariner, either as a a fixed or a revolving light. The general result of all the observations made in respect of haze showed incontestably that the single electric light, as shown from the A tower, greatly excelled the most powerful superposed gas or oil light in penetrating power, either as a fixed or revolving light. Of 284 eye observations recorded as made in weather not clear, but without actual fog, the mean percentage of superiority of the electric light over gas was about 36, and over oil 41. The general verdict of superiority of the electric light in such conditions of weather was plain and unmistakable. It was always better than anything else. In actual fog, the electric light again held its own, and it was proved beyond question that the single electric light pierced a greater depth of fog than the highest powers of either gas or oil; while the quadriform gas and triform oil lights were practically equal in fog. The recorded distance to which lights were carried, or where they were picked up in the fog, ranged mostly between 700ft. and 2,000ft. from the lights themselves; and the superiority of the electric light was determined by its penetrating 200ft. or 300ft. further than the gas or oil lights. But for the purposes of navigation a difference in the visibility of the lights of 200ft. or 300ft. was of no value whatever. The whole result might be approximately stated as follows:—For expenditure of raw material only, without reference to plant, labour, &c., a six-wick mineral oil lamp burning for six hours would consume four gallons of oil at 6d. = 2s., or, say, 3s., including wicks, cylinders, &c. A 108 jet burner alight for the same period would consume 1,800 cubic feet of gas, at a cost of not less than 10s. for coal alone. Taking all these considerations into account, it would not be surprising to hear that the final conclusion of the committee was:—"That for ordinary necessities of lighthouse illumination mineral oil is the most suitable and economical illuminant; and that for salient headlands, important landfalls, and places where a very powerful light is required, electricity offers the greatest advantages."

At the conclusion of the paper there was a short discussion, in which the chairman, Prof. Adams, Mr. Vernon Harcourt, F.R.S., and others took part.

ELECTRIC LIGHTING ACT (1882) AMENDMENT BILL.

(Introduced in the House of Lords by Lord Rayleigh.)

Whereas it is expedient that undertakings for electric lighting should be put in the same position with gas undertakings, both as regards the privileges and the obligations of undertakers, and for this purpose it is necessary to amend and extend the Electric Lighting Act, 1882. Be it enacted, &c.:—

Sections 1 and 2 relate to definitions.

3. Section 12 of the Electric Lighting Act, 1882, shall be read and construed as if the portion of Sub-section 2, commencing with the words "and with respect to waste," and ending with the words "approved of by the undertakers," had been omitted, and instead be it enacted as follows:

4. Every person who shall lay or cause to be laid any conductor to communicate with any electric line belonging to the undertakers without their consent, or shall fraudulently injure any meter used for ascertaining the quantity of electricity consumed or supplied, or who, in case the electricity supplied by the undertakers is not ascertained by meter, shall use any lamp other than such as has been provided or approved by the undertakers, or any lamp calculated to expend more electricity than he has contracted to pay for, or shall keep the lights burning for a longer time than he has contracted to pay for, or shall otherwise improperly use or expend such electricity, or shall supply any other person with any part of the electricity supplied to him by the undertakers, shall forfeit to the undertakers the sum of *five pounds* for every such offence, and also the sum of *forty shillings* for every day such conductor shall so remain, or such works or lamp shall be so used, or such excess be so committed or continued, or such supply furnished, and the undertakers may cut off the supply of electricity from the house and premises of the person so offending, notwithstanding any contract which may have previously been entered into: Provided that nothing herein contained shall, where the damage sustained by the undertakers is in excess of the sums to be forfeited as aforesaid, prevent the undertakers from recovering such excess from the consumer by action.

Sections 5 and 6 relate to penalties for wilful damage, &c.

7. Section eighteen of the Electric Lighting Act, 1882, is hereby repealed, and instead thereof be it enacted that where electricity is supplied by meter no local authority, company, or person shall be at liberty to use any form of lamp or burner, or to use the electricity supplied to them for any purposes, or to deal with it in any manner so as to unduly or improperly interfere with the supply of electricity supplied to any other local authority, company, or person by the undertakers, and if any dispute or difference arises between the undertakers and any local authority, company, or person entitled to be supplied with electricity under this Act or any license order or special Act as to the matters aforesaid, such dispute or difference shall be determined by arbitration.

8. Section twenty-seven of the Electric Lighting Act, 1882, is hereby repealed.

9. Where any undertakers carrying on the business of supplying electricity for their own benefit are authorised by provisional order or special Act to supply electricity within any area, the amount of profit to be

Digitized by Google

received by the undertakers in respect of their undertaking within such area shall be regulated as follows:

(1.) The profits of such undertaking to be divided amongst the undertakers in any year shall not, save as hereinafter provided, exceed the prescribed rate, or where no rate is prescribed exceed the rate of *ten pounds* per centum per annum (which prescribed rate or rate of *ten pounds* per centum, as the case may be, is hereinafter referred to as the standard rate of dividend) on the paid-up capital which shall be authorised by the order or special Act, and shall from time to time be appropriated to and expended on or in connection with such undertaking, unless a larger dividend be at any time necessary to make up the deficiency of any previous dividend which shall have fallen short of the said yearly rate: Provided that the undertakers may increase and shall diminish such standard dividend by relation to a decrease or increase in the standard price (to be fixed by the order or special Act) per electrical unit, in accordance with the principle of the sliding scale now applied to gas undertakings, except that having regard to the small price charged per electrical unit as compared with the price charged per one thousand cubic feet for gas, the standard dividend shall be reduced or increased by *five shillings* in the one hundred pounds per annum in respect of every *one farthing* (instead of as in the case of gas every one penny) charged in excess or in diminution in any year of such standard price per electrical unit:

(2) If the clear profits of the undertaking in any year amount to a larger sum than is sufficient, after making up the deficiency in the dividends of any previous year as aforesaid, to make a dividend at the maximum rate hereinbefore authorised, the excess beyond the sum necessary for such purpose shall from time to time be invested in Government or other securities, and the dividends or interest arising from such securities shall also be invested in the same or like securities in order that the same may accumulate at compound interest until the fund so formed amounts to the prescribed sum, or if no sum be prescribed a sum equal to *one-tenth* of the nominal capital of the undertakers appropriated to the undertaking, which sum shall form a reserved fund, to answer any deficiency which may at any time happen in the amount of divisible profits, or to meet any extraordinary claim or demand which may at any time arise against the undertakers, and if such fund be at any time reduced it may thereafter be again restored to the said sum, and so from time to time as often as such reduction shall happen:

(3.) Provided always that no sum of money shall be taken from the said fund for the purpose of meeting any extraordinary claim unless it be first certified in England or Ireland by two justices, and in Scotland by the sheriff, that the sum so proposed to be taken is required for the purpose of meeting an extraordinary claim within the meaning of this Act or the order or special Act:

(4.) When any such fund shall by accumulation or otherwise amount to the prescribed sum or *one tenth* of such nominal capital as aforesaid, as the case may be, the interest and dividends thereon shall no longer be invested, but shall be applied to any of the general purposes of the undertaking to which the profits thereof are applicable:

(5.) If in any year the profits of the undertaking divisible amongst the undertakers shall not amount to such maximum rate as aforesaid, such a sum may be taken from the reserved fund as with the actual divisible profits of each year will enable the undertakers to make a dividend of the amount aforesaid, and so from time to time as often as the occasion shall require.

10. Where under any provisional order or special Act authorising a company to supply electricity within any area, a certain sum has been prescribed as the original capital appropriated to the undertaking within such area, then when under any further provisional order or special Act any additional capital is to be created and issued in respect of such undertaking, the undertakers shall, notwithstanding anything contained in the special Act or Memorandum or Articles of Association or other document under which they are incorporated, offer the same for sale by public auction or by tender within the metropolis or other prescribed place, in such manner, at such times, and subject to such conditions of sale as the undertakers shall from time to time determine: Provided that—

Here follow provisions similar to those in force relating to Gas Companies' Shares, concluding as follows:—

Where under such order or special Act a local authority or person other than a company is authorised to supply electricity within any area, any new or additional capital issued in respect of the undertaking within such area shall be offered by public auction according to rules prescribed, or if no rules are prescribed then as nearly as the case will admit in the manner hereinbefore provided in the case where the undertakers are a company.

11. The undertakers shall upon being required so to do by the owner or occupier of any premises situate *within twenty-five yards* from any main of the undertakers, or such other distance as may be prescribed, give and continue to give for the purpose of lighting a supply of electricity for such premises under such pressure in the main as may be prescribed, and they shall furnish and lay any electric service line that may be necessary for such purpose, subject to the conditions following (that is to say):—

The cost of so much of any electric service line for the supply of electricity to any owner or occupier as may be laid upon the property of such owner or in the possession of such occupier, and of so much of any electric service line as may be laid over a greater distance than *thirty feet* from any main of the undertakers, although not on such property, shall be defrayed by such owner or occupier.

Every owner or occupier of premises requiring a supply of electricity as aforesaid shall—

Serve a notice upon the undertakers at their offices specifying the premises in respect of which such supply is required and the day (not being an earlier day than a reasonable time after the date of the service of such notice) upon which such supply is required to commence;

Enter into a written contract with the undertakers (if required by them so to do) to continue to receive and pay for a supply of electricity as aforesaid for a period of at least *two years* of such amount that the rent payable for the same shall not be less than *twenty pounds* per cent. per annum on the outlay incurred by the undertakers in providing any electric service line to be provided by them for the purpose of such supply; and

Give to the undertakers (if required by them so to do) security for the payment to them of all moneys which may become due to them by such owner or occupier in respect of any electric service line to be furnished by the undertakers and in respect of electricity to be supplied by them:

Provided always that the undertakers may, after they have given a supply of electricity to any premises, by notice in writing require the owner or occupier of such premises within *seven days* after the date of the service of such notice, to give to them security for the payment of all moneys which may from time to time become due to them in respect of such supply in case such owner or occupier has not already given such security, or in case any security given has become invalid or is insufficient, and in case any such owner or occupier fails to comply with the terms of such notice, the undertakers may if they please discontinue the supply of electricity for such premises so long as such failure continues.

12. The undertakers shall supply electricity for street lighting by any lamps of an electrical character to be approved by the undertakers, within the distance of *fifty yards* from any of the mains of the undertakers, in such quantities as the local authority may from time to time require to be supplied, and the price to be charged by the undertakers, and to be paid to them for all electricity so supplied shall be settled by agreement between the local authorities and the undertakers, and in the case of difference by arbitration, regard being had to the circumstances of the case and the prices charged to private consumers in the district. Any difference which may arise between the undertakers and any local authority in relation to the supply or consumption of electricity to or by such local authority shall be settled by arbitration.

13. All undertakers authorised by provisional order or special Act to supply electricity within any area shall, unless prevented by necessary repairs or unavoidable accident, at all times keep all their mains supplied with electricity up to the prescribed pressure.

14. Whenever the undertakers neglect or refuse to give for the purpose of lighting a supply of electricity to any owner or occupier of premises within the area of authorised supply entitled to the same up to such pressure as is prescribed, they shall be liable to a penalty not exceeding *forty shillings* for each day during which such default continues:

Whenever the undertakers neglect or refuse to supply electricity as by this Act required for street lighting in accordance with the provisions of this Act, they shall be liable to a penalty not exceeding *forty shillings* for such default:

If it shall be proved to the satisfaction of any two justices, not being shareholders in the undertaking, after hearing parties that on any day the electricity supplied by the undertakers was below the prescribed pressure, the undertakers shall in every such case forfeit and pay to the local authority, or other persons, making application for testing the electricity such sum not exceeding *twenty pounds* as the justices shall determine:

Provided that no forfeiture shall be incurred in any case with respect to which it is proved that the insufficiency of pressure was occasioned by unavoidable cause or accident.

[Here follow further provisions as to how the penalties are to be borne and enforced.]

15. Where any undertakers are authorised by license, order, or special Act to supply electricity within any area, any local authority (being an urban authority within the meaning of the Public Health Act, 1875) within whose jurisdiction such area or any part thereof is situated, may (with the sanction of the Board of Trade), by agreement with such undertakers, purchase, and such undertakers may sell to them their undertaking or so much thereof as is within their jurisdiction upon any terms, and on the terms of such purchase being carried out the powers of such undertakers so far as relates to such area or the part thereof within such jurisdiction shall be transferred to and vest in such local authority.

16. All offences and penalties under this Act, and all money forfeited and all money and costs by this Act directed to be recovered as penalties, may be prosecuted and recovered before a court of summary jurisdiction.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS, March 5.

The adjourned debate on the Post Office Submarine Telegraph Contract (St. Vincent to the West Coast of Africa) was resumed. On the question being put "That the contract dated the 19th day of January, 1886, for the construction of a submarine telegraph line from the Island of St. Vincent to the West Coast of Africa be approved,"

Mr. Henniker Heaton said he rose to oppose the motion, and to move as an amendment "that the whole question should be referred to a Select Committee of the House." The cable which under this contract the Government agreed to subsidise for the purpose of its construction was already constructed when the contract was entered into on the 19th of January, 1886. The cable was constructed by the India Rubber and Gutter Percha Company, and it seemed to him that the Treasury minute on this subject was entirely misleading. The person at the bottom of this matter was a gentleman who was greatly mistrusted by those who had any knowledge of these matters—he meant

Digitized by Google

Mr. John Pender; and in asking for a Select Committee to examine into all matters connected with this contract he thought he was making a very reasonable request of the Government. The contract which the House was now asked to sanction bound the British Government to pay £380,000 for the construction of a telegraph cable from St. Vincent to the West Coast of Africa. The company had already a line of cable on the East Coast of Africa, for which the Government paid a subsidy of £25,000 a year. By now obtaining the contract for the West Coast of Africa the Company would obtain a practical monopoly, and he was sure that the House would not submit to a contract of this nature being entered into without the most searching inquiry. He believed that the time had come for the Government of this country to own these cables that connected England with our great colonies, and the effect of this contract was to throw the monopoly of the cable to Australia into the hands of John Pender and Company. While these large subsidies were being paid to one company there was no hope of inducing the Government to construct cables themselves. He had already given notice of motion to the effect that the Government should construct an alternative line of cable round the West Coast of Africa to the Cape of Good Hope, but if this contract were approved his proposal could not be adopted. As announced in *The Times* of the 13th of October, the Gutta Percha Company agreed to construct the cable from St. Vincent to the West Coast of Africa and thence to the coast of Australia without subsidy. Without warning John Pender and Company came in, and after the cable had been laid down, purchased the rights of the company, and now endeavoured to obtain a large sum of money from the Government as a subsidy for the construction of the cable, although, as a matter of fact, it was already laid down and almost in operation. If an inquiry were granted he would pledge himself to produce evidence to show that the contract was not an honest one. He begged to move that the matter be referred to a Select Committee of the House.

Sir H. HOLLAND defended the late Government, and said, although it was true that the India Rubber Company had agreed to lay down a line from St. Vincent, the line was a quasi-foreign one with which they could make no terms. The hon. member said that the Company had now established a monopoly and could charge what rate they pleased, but if he looked at the contract he would see that the rates were laid down and fixed by it. Both the companies tendered, and they both required a subsidy. He denied that they had laid the line in July last. The late Secretary of State for War and the late Colonial Secretary and he himself went again and again over the question of the amount of the tenders and the amount of the subsidy; and the result was that it was reduced to £19,000, which was lower than the subsidy required by the India Rubber Company. The Treasury had no option but to take the best terms they could obtain from the Company that would lay down the line to the West Coast of Africa.

Mr. H. FOWLER said that the charge of the hon. member for Canterbury was that they were entering into a contract that was not an honest one. Now, that question had been before three different Governments for a succession of years, and it had been most carefully considered. The matter involved two points—namely, a question of policy and a question of internal administration. On the first question he frankly conceded that the House had both the right and the duty to express its own opinion. That question was whether it was for the political and the commercial interests of this country that a telegraph cable should be laid to the West Coast of Africa. If the House referred to the Treasury minute of February they would find that the Treasury were of opinion that that scheme would be of advantage both to the West African colonies and to this country commercially and politically. The question was raised in the first instance under the former Administration of the present Prime Minister, and it was considered by the Cabinet of that day that it was for the interests of this country that there should be telegraphic communication with our settlements in West Africa. Anybody who was aware of the grave public inconvenience that had been suffered from the want of that means of communication would be of opinion that the Cabinet decided rightly. That decision was confirmed by the Cabinet of Lord Salisbury, and again by the present Government. The Treasury invited tenders, and they received three, one of £23,000, another of £29,000, and another as high as £102,000. They decided to accept the one for £23,000. There was a difficulty in the way, arising in connection with the Island of St. Vincent not being British territory; but that difficulty having been got over, the company was in a position to complete the contract. Negotiations were opened, and he must express his admiration of the manner in which the late Chancellor of the Exchequer was enabled to reduce the subsidy to £19,000, of which the colonies themselves would contribute £5,000. The English Government were only to pay half rates; they were to have priority for their messages and to have the right to nominate a director to protect their interests; while in time of war they were to take possession of the telegraph. The House was asked to withhold its confidence from the Treasury, and to refer the contract to a Select Committee. That was not the mode in which the public business either had been or ought to be conducted. The hon. member for Canterbury, before he concluded, had rather unveiled what was behind. The hon. member said he was very anxious that there should be another cable laid to Australia, and that the Government should own all those submarine cables. They knew what that meant. They knew that the Government paid between £10,000,000 and £11,000,000 sterling for the purchase of the telegraphs, which, he supposed, were not worth above half that sum. And now probably some people would like the Government to buy up the submarine telegraphs also. He, however, hoped that the Government would do nothing of the kind.

Mr. LABOUCHERE criticised the contract, and strongly supported Mr. Heaton's amendment.

Mr. MUNDELLA said the negotiations for this contract had been commenced by the last Liberal Government and concluded by the late Government on the most economical terms, and he could not understand the hon. member for Northampton opposing it. The contract was put up for tender, and one tender was for £23,000 a year, another for £29,000 a year, and a third for over £100,000 a year. The late Chancellor of the Exchequer reduced the first tender to £19,000, and at that sum the contract was concluded, special care being taken in regard to the terms and conditions, and it being arranged that £5,000 a year should be paid by the colony towards the £19,000. Under such circumstances he hoped the House would not be misled by the hon. member for Northampton.

Sir M. HICKS-BEACH said he took immense trouble with this contract, and he believed that in the tender as cut down to £19,000 the country had an exceedingly good bargain. This cable would save many thousands a year by securing telegraphic communication between this country and our colonies in Africa, and thus tending to guard us from native wars. The commercial advantages would also be very great.

Mr. MOLLOY asked whether it was not a fact that the India Rubber Company, a solvent company, were prepared to lay the cable at their own expense, and that some person stepped in, purchased the contract, and then came to the House for a large subsidy. Unless a more satisfactory explanation than had been as yet given was furnished he should oppose the vote.

Mr. MUNDELLA begged to state, by permission of the House, what had been already stated half a dozen times, that the India Rubber, Company asked for £29,000 a year, that they only laid a small section of the cable, and when they got the contract for the whole distance they handed it over to another company who did it for £19,000.

After some further remarks by Mr. ILLINGWORTH and Sir E. STANLEY, Mr. H. FOWLER said, in answer to Mr. BRUNNER, that the India Rubber Company asked between £20,000 and £30,000. The company proceeded to lay a small portion of the cable—about one-sixth of the whole—and ultimately when they got the complete contract they sold the cable they had laid, with their rights, to a company with whom his right hon. friend opposite arranged better terms.

The House divided, and the numbers were—for the amendment, 34; against, 199; majority, 165; after which the motion was agreed to.

COMPANIES' MEETINGS & REPORTS.

The India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

An extraordinary general meeting of this Company was held on Tuesday, at the offices, 106, Cannon-street, E.C., Mr. S. W. Silver in the chair.

Mr. WM. J. TYLER (the secretary) having read the notice convening the meeting,

The CHAIRMAN said that this was a formal meeting to confirm the resolutions passed at the extraordinary general meeting, held on the 18th February. He would read No. 1:—"The Board of Directors may from time to time appoint one of their number or any other person to be a managing director of the Company, and may determine the amount of his remuneration and the terms of his engagement, but no such engagement shall be for a longer period than five years. A managing director shall not retire from office during the period of his engagement." He moved the confirmation of that resolution.

Mr. SCOTT seconded the motion.

Mr. CATOR said he saw by the last balance-sheet that the remuneration of the Board was a minimum of £2,000, and the extra was £2,695, giving to each of the four directors £1,173. If the number of directors were to be increased to seven, including the managing director, and if the remuneration were increased in the same proportion, then the remuneration of the directors would be the large sum of £6,874; and if the Managing Director were to receive more than the rest, then, of course, the sum would be much larger still, and would be much more than was paid to the directors of another similar company.

The CHAIRMAN said the answer was that the maximum was £5,000, according to a motion made some years ago, which would not in any way be interfered with.

The SOLICITOR said the amount could never exceed £5,000.

The motion was then put and carried unanimously.

The CHAIRMAN then moved the confirmation of the second resolution, viz.:—"The number of Directors (including any managing director) shall not exceed seven nor be less than four, and every Director shall hold at least 100 shares in his own name as the sole holder thereof. The Directors may from time to time appoint any additional Directors or Director, provided the number shall not exceed seven."

The motion was seconded by Mr. SCOTT and carried.

The CHAIRMAN moved the confirmation of the following resolution: "The remuneration of the Directors, other than a managing director, shall be, from time to time, determined by the members at the ordinary meeting, but any proposal for the alteration of the remuneration of Directors shall be deemed special business, requiring seven days' notice to be given thereof."

Mr. SCOTT seconded the motion, which was carried.

On the motion of the CHAIRMAN, seconded by Mr. SCOTT, the fourth resolution was also confirmed, viz.:—"The Directors may from time to time sell, lease, exchange, or otherwise dispose of and deal with all or any part of the property of the Company situated in France upon such terms and in such manner as they may think expedient."

Mr. CATOR asked if the £5,000 maximum remuneration included the salary of the Managing Director.

The CHAIRMAN: Oh, no, not at all.

REESE LIBRARY OF THE UNIVERSITY CALIFORNIA
Digitized by Google

Mr. CATOR: Could you give us some notion of what the remuneration to the Managing Director would be?

The CHAIRMAN: You were not present at the general meeting.

Mr. CATOR: No, I was not, unfortunately.

The CHAIRMAN: That was gone into and discussed.

Mr. CATOR: Was it named?

The CHAIRMAN: No; the shareholders distinctly objected to it.

Mr. GRAY: I offered to tell them all about it, but they would not have it.

Mr. CATOR: Well, I think that is most extraordinary.

The CHAIRMAN: As a trading Company, it was considered inadvisable.

Mr. CATOR: I do not think myself there could be the slightest possible objection to such a thing as that being made known to the proprietary of a company. The more openly these things are declared to the Company, I think myself, the better. I do not see why anything should be kept a secret. You see, these questions cannot be opened without some trouble afterwards. Here is a distinct thing in your notice:—You guard yourselves by saying you must have seven days' notice, and I know from experience, belonging to a number of companies, what a difficulty there is in opening these questions again, and therefore it is far better to have the thing settled on the spot while we are all here than postpone it for disagreeables afterwards.

The CHAIRMAN: I think I may say that the subject was disposed of and decided at our meeting on the 18th ult.

The SOLICITOR: Not by the Directors.

The CHAIRMAN: Not by the Directors at all, but by the shareholders.

Mr. CATOR continued to remark that the remuneration to the Directors would be a very large sum to this Company. They did not pay as high a dividend as formerly, and the shares did not stand as high.

The CHAIRMAN said the business was concluded.

On the motion of Dr. SMALL a vote of thanks was passed to the Chairman and Directors, and the proceedings then terminated.

National Company for the Distribution of Electricity by Secondary Generators (Limited).

Report of the Directors to be presented at the third ordinary general meeting of the shareholders, to be held on Thursday, the 18th inst., at the offices of the Company, 18, Warwick-street, Regent-street, W., at twelve o'clock:—

The anticipation of a profitable business which the Directors ventured to express in the report presented to the shareholders at the general meeting held on the 9th February, 1885, is being realised. The seven months of 1883, and the whole of 1884, formed a period of preliminary work undertaken with a view to demonstrate the Company's system. The amounts expended on the trial installations on the Metropolitan Railway and at Turin, though large, seem to have been fully justified by results. The accounts submitted to the meeting show a profit of £4,570. 10s. 7d., after deducting all expenses. After writing off from this balance £574. 4s. 2d. for depreciation of plant and a proportion of preliminary and other expenses, there is a net balance of £3,996. 6s. 5d., out of which the Directors propose to pay a dividend on the Preferred shares at the rate of 10 per cent. per annum, from the respective dates of allotment to 31st December, 1884, which will absorb £2,207. 6s. 4d., leaving to be carried forward £1,789. 0s. 1d. An amount of £1,087. 16s., received from the Banque d'Escompte de Paris on 13th of February in this year, as balance of the guaranteed minimum for the year ending 1st Feb., 1885, does not enter into the 1885 accounts, although 11-12ths were really earned in 1885. The installation at the mines and works at Aschersleben, in Germany, has been in operation for a considerable period, and is being extended. The installations at Turin and Tivoli, though progressing satisfactorily, are less advanced. The profits of these works will appear principally in the accounts of the current year. The Directors, therefore, have pleasure in pointing to the fact that the profits for the current year have already a a considerable basis from matured business, while the prospect of new business is promising from several quarters. The Directors have pleasure in announcing the conclusion of a contract with Mr. George Westinghouse, jun., of Pittsburg, for the working of the company's patents in the United States of America. The character and position of Mr. Westinghouse justify the expectation of important results from this arrangement. As in the case of the Banque d'Escompte, Mr. Westinghouse guarantees a minimum annual return to the Company. The shareholders are probably aware that a gold medal was awarded to the Company at the Inventions Exhibition, South Kensington, "for the successful working out of a system of distribution of electricity by induced currents." The installation at the Grosvenor Gallery, undertaken by Sir Coutts Lindsay and Company, is not yet complete. In regard to this installation, the Company has no responsibility beyond the supplying of their apparatus. The successful opening of the installation at Tours, under the direct supervision of the chief engineer of the Company, has produced a marked impression in France, and promises to lead to a large employment of the system there. In order to enable the payment of the dividend now recommended, without crippling the resources of the Company, the Directors waive their claim to remuneration up to the end of 1885. The Directors believe the time is not far distant when a dividend on the Ordinary shares may be looked for; they base this expectation on the growing appreciation of the system by scientists and the public. Mr. D'Oyly and Sir J. Mackenzie, the directors who retire by rotation, offer themselves for re-election. In pursuance of Article 70, Mr. Gustav Dufresne was elected to fill the vacancy on the Board of Directors occasioned by the death of Mr. Le Fez. This appointment will be proposed for confirmation. Mr. J. H. Thornton, the retiring auditor, will be proposed for re-election for the current year.

The Telephone Company of Egypt (Limited).

Report of the Directors for the year ended 31st December last, to be presented at the third ordinary general meeting of the Company, to be held at the office of the Company, 14, Austin Friars, E.C., on Tuesday, the 16th inst., at 12 o'clock.

The Directors are glad to be able to state that the business of the Company has been very materially extended during the period under review. The profit and loss account, including the balance of £165. 3s. 6d. brought forward from last year, after providing for income tax and writing off a sum of £300 in reduction of capital for depreciation, exhibits an available balance of £3,210. 0s. 8d., out of which your Directors recommend the payment of a dividend at the rate of 5 per cent. per annum. This will absorb £3,017. 15s., and leave a balance of £192. 5s. 8d. to be carried forward. The dividend now payable has, in accordance with the Articles of Association, to be applied in the following manner, viz.:—2 per cent. in final payment of the cumulative preferential dividend of 7½ per cent. for 1883; 3 per cent. in part payment of the cumulative preferential dividend of 7½ per cent. for 1884; leaving 4½ per cent. for that year still due. In order, however, that the earings of the present and future years may be applied specially to the payments of dividends for those years for which the accounts are issued, an alteration of the Articles of Association is now contemplated. The following figures will show the increase that has taken place during the last three years of the Company's existence:—

	1883.	1884.	1885.	Increase in 1885.
Total number of subscribers in Egypt...	454	547	714	167
Gross revenue................	£6,400	£7,014	£8,650	£1,636

The full benefit of the increase for the past year does not appear in the accounts now published. The revenue accrued for 1885 being £7,584 against a present gross revenue exceeding £8,650. Recent advices from the manager give encouraging accounts of prospects generally. In accordance with the Articles of Association General Fraser, C.B., R.E., the Chairman of the Company, retires from the direction, but being eligible, offers himself for re-election. Messrs. Price, Waterhouse and Co., the auditors of the Company, also retire, but offer themselves for re-election.

NOTES.

INTERRUPTION OF CABLE.—*The Times* correspondent reports, under date March 16, that telegraphic communication is interrupted between Ava and Myingyan.

GERMAN UNION TELEGRAPH COMPANY.—This company announce a final dividend for the year 1885 of 4s. 3d. per share, making a total distribution of 10s. per share.

THE TELEPHONE AT PEMBROKE.—At the last meeting of the Pembroke Township Commissioners it was agreed that the Town Hall should be put in telephonic communication with the Exchange at a cost of £16. 10s.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 15th instant are £2,892, as compared with £2,865 in the corresponding period of 1885.

ACCIDENT.—On Monday afternoon at Willenhall a man named William Miller, of Birmingham, was engaged fixing a telegraph insulator on the top of a building in the market-place, when he fell into the street below and died in a few minutes.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 12th inst. were £2,449, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE FOLKESTONE ART TREASURES EXHIBITION.—According to present arrangements, the National Art Treasures Exhibition at Folkestone will be opened on or about 7th May. The ceremony, it is expected, will be performed by the Prince and Princess of Wales.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this institution will be held at 25, Great George-street, S.W., on Thursday, 25th inst., at 8 p.m., when the following paper will be read, "Electric Lighting by Means of Low Resistance Glow Lamps."

SUBMARINE CABLES.—For the purpose of securing certain bonds or debentures of the company, aggregating £600,000, or $3,000,000, the Commercial Cable Company has executed a trust deed of the franchises, rights and cables to Ernest W. Siemens and Johann C. L. Loeffler, of Berlin, Germany, and Westminster, England, respectively.

POST OFFICE EXTENSION.—The Post Office authorities intend to give every facility for convenient removal to those persons in the neighbourhood of St. Martin's-le-Grand whose premises are required for the Post Office extension. Some of the present occupiers will have the option of removing either at Midsummer, Michaelmas, or Christmas this year.

LIGHTNING.—Mr. W. McGregor sends us a pamphlet explanatory of a proposed new society, which is to deal with the protection of life and property from lightning. We are of opinion that at the present time there are enough societies in existence, and that any work in connection with lightning protection may be very well undertaken by some of the older societies.

OBITUARY.—The death is announced in Paris of M. Felix Seblanc, professor of chemistry at the Central School of Arts and Manufactures, gas analyst for the City of Paris, and vice-president of the Society for the Encouragement of National Industries, &c. M. Seblanc, who was for a long time the *collaborateur* of Dumas, was directly connected with some remarkable discoveries in chemistry, and was no mean electrician.

THE PAN-ELECTRIC SPECULATION.—Our American namesake is of opinion that free trade in telephones, should it be established, will not be of the slightest benefit to the people at large. Out of the million of inhabitants within telephonic speaking distance of New York City Hall, it is doubtful if 2 per cent. would pay even the Indiana legal rate of three dollars per month.

THE POST OFFICE TELEGRAPHS.—The *Manchester Courier* states that it is satisfactory to be able to say a word for the efficiency of the telegraph department of the Post Office. During the present winter there have been numerous snowstorms, and none of the "news" wires connected with the provincial newspapers have been interrupted from any cause, although in previous years one snowstorm was sufficient to inflict a large amount of interruption.

THE TELEPHONE IN LUXEMBOURG.—The Chamber of Deputies of the Grand Duchy of Luxembourg has decided that in addition to the telephone system which was opened in Luxembourg in October last, the whole of the towns in the Duchy shall be telephonically connected. The number of subscribers amounts at present to 120. The apparatus employed in the system is electro-magnetic throughout, and the lines are of phosphor bronze upon iron poles.

TOWN LIGHTING.—The electric light has recently been installed in Modane, a small town of 2,400 inhabitants, in Savoy. The motive power is furnished by the River Arc, of course by means of turbines. The dynamos, which are upon the Thury system, have been furnished by Messrs. Meuron and Cuenod, of Geneva. The lamps are Edison incandescent. It is announced that the municipality of Salzburg, in Austria, have decided to let a concession for the electric lighting of the town.

THE ELECTRIC LIGHT FOR STEAMSHIPS.—Following the wise example of the P. and O. and other large steamship companies, the Royal Mail Company has just had its steamship "Trent" fitted with the electric light, at Southampton. It is probable that the company will—provided that the present installation prove satisfactory—introduce the electric light on all the steamships under its direction. The substitution of incandescent lamps in place of the oil lamps now in use would undoubtedly add greatly to the comfort of the passengers.

INSURANCE.—The Scottish Economic Life Assurance Society sends us a communication respecting their method of dealing with the insurance of electrical engineers, discussed recently in our columns, but it will suffice if we refer intending insurers to the company for information. We have called attention to the disability under which electrical engineers have laboured. We are most emphatic in our opinion that the risk run by electrical engineers is no worse than that of other engineers, and no exceptional treatment is required in dealing with their insurance.

EARTHQUAKE SHOCKS ON THE CONTINENT.—A Reuter's telegram, dated Madrid, March 15, says:—A strong shock of earthquake was felt last night in the province of Granada, causing great alarm among the inhabitants. No damage was done in the capital, but it is reported that several villages have suffered to some extent. The shocks were oscillatory from west to east, and accompanied by a rumbling noise. Another telegram, dated Wiesbaden, March 15, says: A violent shock of earthquake was felt here at twenty-eight minutes past midnight.

Digitized by Google

AN ECONOMICAL TELEPHONE SYSTEM.—The Supreme Court of Indiana has affirmed the decision of the Marion County Criminal Court in the case of the State against John E. Hocket, the issues involved relating to the law reducing the rentals of telephones in the State from five dols. to three dols. a month, with a corresponding reduction for services to other towns. The decision is that the law is constitutional, and that the extra charges above three dols. a month made by the company for alleged service, &c., are illegal, as by the word "telephone" the law meant all the appliances in connection with the service.

PORTLAND LIGHTHOUSE.—In the House of Lords on Friday night, Lord Colville of Culross called attention to the inferior nature of the light now exhibited at the north end of Portland Breakwater, and asked the First Lord of the Admiralty whether, considering the importance of Portland as a harbour of refuge, it was intended to replace the existing red light by one of greater power? The Marquis of Ripon replied that directions had been given to the harbour master to report fully on the character of the light, which was calculated to be visible at a distance of eight miles. He admitted fully the importance of having an efficient light at that place.

THE STREET LIGHTING OF CARNOUSTIE. — Intimation having been received by the directors of the Carnoustie Gas Light Company that they desired to withdraw from the arrangement made in 1862 for the lighting of the streets, a meeting of the ratepayers was held on Friday evening to consider what steps should be taken for lighting the street lamps in future. The agreement with the gas company was read and discussed, and Captain M'Corquodale, who occupied the chair, remarked that as before next winter the Police Bill now before the House of Lords would be law, and the circumstances might be naturally altered, he suggested that a committee should be appointed to attend to the interests of the inhabitants. This was agreed to, and an influential committee was elected.

ELECTRO-CHEMISTRY.—The current issue of the *Comptes Rendus* contains an interesting note upon the electrolysis of salts, relating principally to galvanoplasty. The experiments of M. Renard are borne out in several important points. In known solutions it is believed that the quantity of metal precipitated is proportional to the temperature. This proportion, however, would appear to increase in the inverse ratio to the density of the liquid. When the distance of the electrodes is successively doubled, the quantity of metal precipitated decreases in geometrical progression so long as the distance is less than 32 centimetres. Above this value the law is not applicable. When the two electrodes are identical the quantities of metal precipitated are proportional to the square root of their surfaces.

LIGHTING BY PRIMARY BATTERIES.—At the recent meeting of the National Electric Light Association in America, Mr. Allen V. Garratt said:—"A primary battery, capable of successfully lighting for a number of hundred hours a single incandescent lamp, or, if necessary, a score of them, is not an invention to be put aside as wholly insignificant. I speak conservatively when I say that it makes not only possible, but feasible, the electric lighting of a single house, a yacht, a parlour, or sleeping car, or even a man's own private carriage. It also places at the disposal of every physician and surgeon a light always ready and requiring but little care, with which he can explore the interior of the human body. I need not suggest other uses for such a light. They suggest themselves to every one. This is a field of electric lighting which is out of the reach of the dynamo machine."

BUCHAREST.—On Thursday, March 5, the first Court Ball was given at the New Palace. It may be remembered that we have from time to time mentioned the progress of the electric lighting being carried out under the supervision of Mr. Francis Jehl, by the Edison Company of Paris. The work was only completed on the day before the ball, so that no prolonged experiments could be made. The current for the lighting of the lamps is supplied from the machine house at the National Theatre, which has been illustrated in our columns. The total number of lamps in the New Palace is 928, in the Old Palace 466, making a grand total of 1,394 lamps. The lamps used are Edison 10-candle lamps. A table of their distribution will be given in our next number. At the ball the lighting was extremely successful and highly appreciated by the twelve hundred guests.

BRASS TAPED CORE.—An exchange says that in the submarine cable laid last year between Mozambique and Zanzibar the insulated core was protected by brass tape. This forms a complete protection against the teredo, which destroys the insulation of the cable. This type of cable is being much used where the teredo is found. Copper tape was used for some submarine cables many years ago, but not for the protection of the insulator. Its application for that purpose is recent, although the plan was patented nearly 20 years ago. Copper tape is also used for protection against land insects in some places where underground wires are necessary, all other methods to protect the insulation having proved ineffectual. Our contemporary is evidently not aware that the cables laid along the East Coast of Africa in 1879 were also brass taped in the same manner as the duplicate Zanzibar-Mozambique which is referred to—that is to say, brass taped as far as the intermediate sections and shore ends are concerned.

LOCAL AUTHORITIES AND TELEPHONE WIRES.—The Bill of the Nelson Local Board came before the Court of Referees, at the House of Commons, on the 8th inst., on the petition of the Lancashire and Cheshire Telephonic Exchange Company, for a *locus standi* to appear against the Bill. The sections of the Bill which affected the petitioners related to overhead wires, and empowered the Local Board to make, alter, or repeal from time to time bye-laws for preventing danger and obstruction to the public by posts, wires, and other telegraphic or telephonic appliances in or across the streets. Powers were also asked for the prohibition of such posts, wires, &c., unless upon conditions to be prescribed by the Local Board, and for the removal of such appliances already in existence, after a period of five years, if the Board should so determine. After some remarks by counsel representing the parties, the Court decided that, as Parliament was very jealous of local authorities obtaining such legislative powers as were sought by the Bill unless the parties affected were heard upon the petition, in this case the *locus standi* would be allowed.

RAILWAY CARRIAGE LIGHTING.—As our readers will be aware, the lighting of railway carriages by electricity is making great strides in France, and recently the Compagnie des Wagons-Lile have been carrying out a course of experiments under the direction of their engineer, Mr. Street, with the system recently invented by M. Lucien Desruelles, the results of which are said to have been of a satisfactory nature. The experiments have been principally carried out on the restaurant cars; each car is lighted by twenty-one incandescent lamps, of which nineteen are of 6 candle-power and two of 3 candle-power. These lamps, with the exception of the two last, which are grouped in series, are placed in multiple arc upon the terminals of the source of electricity, which, in this case, is a primary battery invented

Digitized by Google

by M. Desrulles. Each of the elements weighs 14 kilogrammes and has an E.M.F. of 2·19 volts, giving on short circuit about 35 amperes. Its capacity is about 200 ampere hours. The 21 lamps in each car are supplied by a battery of 45 elements, 15 of which are connected in series and three in multiple arc; in average working the difference of potential at the terminals is 17 volts, and the current about 17 amperes.

THE ELECTRIC LIGHT IN NEW SOUTH WALES.—Messrs. J. and J. Hayes, of the City Steam Flour Mills in Goulburn, N.S.W., have recently introduced several important improvements in their mills. Amongst these is the electric light, the proprietors thus having the honour of first adopting in Goulburn this mode of illumination. The apparatus has been supplied by the Australasian Electric Light Company of Sydney, and has been fitted up by Mr. Barton, in their employ. The power for working the dynamo is communicated by a belt from the driving machinery of the mill. The dynamo, which is placed on the first floor of the mill, occupies hardly more space than a gasmeter, being only 2ft. 6in. long by 1ft. broad and 1ft. high. The dynamo is a Victoria-Schuckert, made by the Anglo-American Brush Electric Light Corporation. It is capable of supplying 40 lights; the number at present used is 20, for which about 3 horse-power is required. The lights are Swan's incandescent. They give a bright soft light; but their great recommendation in the present instance is their safety as compared with naked lights, the danger of explosion in the mill being avoided. This is the reason which chiefly induced the proprietors to adopt the electric light. The first trial of the light was made recently, and the apparatus is now in full working order.

THE ELECTRIC LIGHT IN MANUFACTORIES.—A contemporary has recently had the pleasure of seeing an electric installation in Messrs. Marsland's printworks, Cheadle, which had been carried out by the Manchester and District Edison Electric Light Company. The works lie some distance from the village of Cheadle, and are not supplied with gas, the lighting formerly being done by means of oil lamps, so that the present opportunity was a good one for either putting down a gas plant or an electric light installation; the latter plan has been adopted, and, all things considered, we do not doubt that it was the best thing to do. There have been put down about fifty Edison-Swan incandescent lamps, each of sixteen candle-power, the motor being one of Elwell-Parker's 10in. machines; one of Marshall's 6 horse-power vertical steam engines supplies the necessary power. The engine and motor are well finished and reflect credit upon their respective makers. The usual devices of fusible safety wires are inserted in each room, so that in the event of an excess of current passing through any portion of the circuit, say, from contact of the wires, the fusible part melts out and the lamps in that part of the circuit are cut off; in this way the fault is localised and can be readily found and remedied. Switch taps also are applied to each room, and the work has been done with that care so essential to the success of an electric light installation.

THE TELEPHONE FOR RIFLE MATCHES.—Lieutenant H. de B. Hovell has recently made some interesting experiments at Browndown with the view of ascertaining the utility of the telephone in connection with rifle-shooting matches. The tests have been made at the 600 yards range, where a wire was laid from end to end at the height of about 4ft. from the ground, so as to communicate from the shooting party to the marker behind the butts. The telephone apparatus was attached to two india rubber caps of a similar pattern to those used in her Majesty's ships for diving purposes, one of which was worn by a person at either end of the range. These caps are of a portable description, and can, of course, be attached or detached at pleasure. They comprehend in a very small space a transmitter and a receiver, and were found to act so well that conversation could be heard almost as distinctly as by means of an ordinary telephone. So far the experiment is pronounced to be a success. By its means the officer in charge of a firing squad would be afforded direct communication with the "marker," who in turn could telephone at once the result of each shot, and other additional information. The apparatus is comparatively inexpensive, and it is probable that it will be adopted almost immediately. It could always be ready for use, as the wires can be permanently laid, and the affixing of the other apparatus only occupies a few minutes.

TESTING CARBONS.—The following is suggested as a perfectly fair carbon test:—Take a dynamo machine, with its full complement of lamps, and trim the lamps with the same make of carbons; note the speed of the dynamo carefully, and during the test measure the current at frequent intervals with an ammeter; see that all the lamps burn freely, without hissing, and yet not with arcs so long as to flame. Measure the E.M.F. around each arc with a voltmeter. Burn the lamps until all the carbons are consumed, or burn them, say, for four hours, and then measure the length of carbons consumed, and calculate the total time that they would burn, taking the average result. In testing another make of carbon, pursue the same course. You will now be able to note the difference between various grades of carbons. Some carbons will be soft, and will consume so rapidly as to make them uneconomical; others will be of such high resistance that the machine will not run its full complement of lamps with good long arcs, without increasing its speed. In such a case, a lamp or two could be cut out of the circuit until the arcs are normal, and this would show the degree of economy of the first carbons over the others. It is not infrequently the custom to mix several different brands of carbons on the same circuit of lamps, and then judge of the results entirely by the length of time each carbons burns. Nothing could be further from a real test. A carbon which would burn nine hours would frequently be less economical than a carbon burning eight hours; as generally the latter carbon would enable you to burn, say, two more lamps on a thirty-light circuit than the former. Calculating the rental receipts from these two lamps it would be found that they would more than make up the difference due to more rapid consumption of the eight-hour carbons.

THE ELECTRIC LIGHT IN GERMAN UNIVERSITIES.—An agreement has been entered into between the German Government and the Edison Company in Berlin for the supply of electricity to the university in that city. The necessary works will be carried out during the coming summer holidays, after which the whole of the buildings will be lit by glow lamps and arc lights, to the entire exclusion of gas. The current will be supplied from the central station in No. 85, Friedrichstrasse, and will be used not only for lighting, but also for experimental purposes in the laboratories attached to the university. The primary object of this installation is to afford the Minister for Education in Germany an opportunity of satisfying himself on the applicability of the electric light to schools and other educational establishments; and if the verdict should be in favour of the new illuminant it will be introduced as a general thing in universities and schools. As a matter of fact negotiations are already pending with regard to the introduction of the electric light at the old and world-known university of

Digitized by Google

Halle, and many others of the seats of learning will in due time follow. The observant English tourist, when travelling in Germany, has no doubt remarked what a large proportion of the students wear spectacles, and has been at a loss how to account for this. Whether the affliction of short-sightedness be due to want of outdoor exercise, or to the angular and indistinct character of German print, or to an excessive indulgence in beer and tobacco, as some uncharitable persons maintain, is a question we cannot pretend to answer. Certain it is, however, that with the introduction of the electric light, to the entire exclusion of gas, the affliction of short-sightedness will to a considerable extent be diminished, and at the same time the general health of students will increase.

Electric Lighting at the Leeds Town Hall.—Some time ago the Electric Lighting Committee of the Leeds Corporation resolved to illuminate the Victoria Hall by means of arc lamps, at a cost of about £450. It will be recollected that on the occasion of the last musical festival, in October, 1883, the hall was illuminated by means of incandescent lamps by Messrs. Crompton and Co. The "electroliers" have not been removed, and if the Musical Festival Committee should prefer the incandescent lamp to the arc lamp, they will be allowed to remain until after the Musical Festival in October next, when the Electric Lighting Committee will proceed to fix the arc lamps. Two arc lamps have been suspended in the hall, and the Electric Lighting Committee have had an opportunity of inspecting them. The experiment showed that no fault could be found with the steadiness of the light. There was no flickering or change in the brilliancy, and the committee were so satisfied with the lamps that they have ordered others to be fixed. The installation in its entirety will consist of eight arc lamps, driven by secondary batteries placed in the Municipal Buildings, and the remaining lamps, with the necessary wires, &c., are in readiness to be put up. The lamps, which are the Brockie Pell patent, are connected in parallel. They are of 2,000 candle-power each, and each lamp takes twelve amperes of current. The lamps are fixed upon pulleys, so that they may be varied in height up to 46ft., and the cleaning and renewing of carbons can be effected by a person standing in the body of the hall. E.P.S. batteries are used, of the L type, and their capacity is 500 ampere hours, which will give a ten hours' run for the complete installation. The secondary batteries, which are coupled upon two groups in parallel, are charged by dynamos which the corporation already have in the basement of the Municipal Buildings. These dynamos are compound wound, and are used to light the Public Free Library with incandescent lamps. The current is carried from the basement of the Corporate Offices to the Town Hall along a subway in Calverly-street, and thence into the false roof of the Victoria Hall, from which the arc lamps are suspended. The features of the installation, with which the committee are satisfied, are perfect steadiness of light, absence of noise, and duration of carbon. The lamps, batteries, &c., are supplied by Messrs. Rowbotham and Worsley, of Manchester, and the installation is being carried out to the designs and under the direction of Mr. Thos. Hewson, M.I.C.E., the Leeds Borough Engineer.

Telegraphic Charges.—A deputation from the Association of Chambers of Commerce, amongst whom were Mr. Lewis Fry, M.P., and Mr. J. D. Weston, M.P., recently waited upon the Postmaster-General to lay before him the views of the Chambers in regard to telephones, the registration of telegraphic addresses, and the International Conference. The deputation was introduced by Sir B. Samuelson, M.P. (President of the Association). Two memorials were presented praying for the reduction of the charge for registering addresses, and for a reduction or equalisation of the charges for telephonic communication. The Postmaster-General, in reply, said that the Post Office lost both in time and in money by the system of registered addresses, and the department, therefore, was not anxious to increase the number. The question of the charges for telephonic communication was one of great intricacy, and he did not feel at that moment competent to discuss the large question of the Government taking over the whole telephone management. At the request of the Postmaster-General (who was suffering from a cold), Mr. Patey stated that the result of the International Telegraphic Conference was that the telegraphic rate to India would be reduced from 4s. 7d. to 4s. a word, to Russia from 9d. to 6½d., to Spain from 6d. to 4½d.; and reductions would also be made to other European States and to Australia, and probably other countries in the far East.—The Postmaster-General has recently been memorialised from Yorkshire to reduce the amount charged for the registration of telegraphic addresses from £1. 1s. to 5s. His lordship has replied that the actual cost the department incurs in respect of each registration considerably exceeds the sum of 5s., and that any balance that may remain out of the charge of one guinea is far from being sufficient to meet the loss of revenue arising out of the reduction in the number of words in telegrams which is brought about by the use of an abbreviated address. Apart from the question of expense, the letter states further that the use of abbreviated addresses causes delay, owing to the additional processes having to be gone through in discovering the proper place to which to send the message. If the fee for registration were reduced, the department would be taking a step which would lead the public to believe that the registration of abbreviated addresses was desirable, and a large increase in the number of registrations would probably take place. Lord Wolverton does not think that the department would be acting rightly in taking such a step. In former years abbreviated addresses were used almost solely for foreign telegrams, and the number of registrations was extremely limited; but the system is one which the department could never recommend to the public, and his lordship considers that it would be contrary to his duty to do anything which would encourage any great extension of the system.

A New Torpedo.—The Paulson torpedo system consists in the use of chemically-generated gas, which is utilised either for forcing a column of water direct astern, or for causing it to actuate machinery for driving a propeller. The explosive charge consists of a species of gun-cotton possessing 50 per cent. more power than ordinary gun-cotton, but having an equal degree of safety. The steering device is that upon which Mr. Paulson is most communicative, and this is stated to consist of two batteries, one pole of each of which is placed in connection with the coils of two sets of electro-magnets, from which leads are conducted to two metal pins fixed on a disc of insulating material. Both the other poles of the batteries are placed in communication with a balanced magnetic needle of special construction. The metal pins are placed one on either side of the needle, and the course of the torpedo having been set it is started. Any deviation of the torpedo from its assigned course causes a relative movement of the needle, which touches one or other of the pins, thus establishing the circuit through the coils of one or other of the two magnets. An armature connected with the rudder is attracted, and by this means the torpedo is again placed on its right course. The depth of immersion of the weapon is also regulated and main-

Digitized by Google

tained in a similar manner by a vertically balanced needle. Another feature is that the torpedo can be directed towards iron ships, irrespective of the pre-determined course, by means of another balanced needle. A demonstration of the steering powers of the apparatus was recently given by the inventor at 15, Cockspur-street, Charing-cross, a model torpedo about 2ft. 6in. long and 7in. in diameter being used. The model was not placed in water but was swivelled on a stand, and it was clearly shown that when it deviated from the course upon which it had been laid, the electro-magnetic arrangement—which was of course concealed within the torpedo—came into operation and restored it to its normal course. More could not be shown, but it was stated that a full-sized torpedo, 16ft. in length and 14in. in diameter, had been made and successfully tried on the coast in England. On the last occasion, however, the torpedo had managed to get away from its inventor and had been no more seen. The material of which Mr. Paulson proposes to construct the shell of his torpedo differs from that hitherto used in that it is a species of papier-maché of a tough and fibrous nature. The new weapon is to be discharged from the shore or from any ordinary boat, thus obviating the cost of a special torpedo-boat. This feature points it out as valuable for coast and harbour defence, for which purposes it is the opinion of several naval authorities by whom it has been examined that it is especially adapted. In view of its apparent merits it would appear desirable that the Government authorities, who have had the matter under consideration for some little time past, should lose no time in constructing a torpedo of the proper working size and having it practically tested. This course is the less objectionable seeing that the cost is stated to be only about £150. At any rate the invention appears to justify prompt and thorough investigation in order that its practical usefulness or otherwise may be ascertained.

The Electric Lighting Act.—In view of the second reading of the Bill introduced by Lord Rayleigh to amend and extend the Electric Lighting Act, 1882, a report has been presented by the committee appointed to consider the matter at the instance of the President of the Board of Trade. The committee have arrived unanimously at the conclusion that the electric light companies should demand to be put simply in the same position as the gas companies are, both as regards their privileges and their obligations, inasmuch as they believe no satisfactory solution of the question of general electric lighting can be arrived at by amending the Act on the basis of a modified purchase option clause, and the conclusion itself is clear and intelligible, and will commend itself to the public by its fairness and simplicity. Electric light companies may safely undertake the business of general lighting under conditions entirely similar to those of the gas undertakings, and the committee have prepared the draft of a Bill, which Lord Rayleigh will present to Parliament. While unable to accept any purchase-option clause, the committee think it quite right that all reasonable facilities should be given to local authorities to acquire electric lighting undertakings by agreement. The committee says:—"Amongst other things it is to be remembered that as electric lighting develops and advances in popular estimation, a large and increasing capital will be necessary to extend the system and make the supply still cheaper and more popular. This will be the critical period; and the ultimate success of electric lighting may not be attained until a large portion of the term of the purchase option clause has expired. It is impossible that the new capital can in the remainder of the term earn a fair commercial profit, as well as the means of providing a sinking fund for replacing the loss. The price loaded with the cost of providing a sinking fund would be prohibitive to extended consumption. Any proposed extension of the enterprise at such a time must necessarily be a failure, commercially; the undertakers would be unable to obtain fresh capital in the market; and if there remained any uncalled capital already subscribed, the calls could only be made by a cruel injustice to the shareholders. If electric lighting undertakings are put on a footing of equality with gas, central station lighting will at least be tried on a scale sufficient to make the competition with gas serious. The executive committee believe that such undertakings will, through difficulties, achieve ultimate success. The possibility of electric lighting as a large and popular industry now hangs in the balance, and if the committee should adopt our recommendation to demand that the electric lighting industry shall be put on the same footing as gas, we think it fair that the argument should be respectfully urged on the Board of Trade, that if this reasonable demand is not conceded, upon them will rest the responsibility for the failure of electric lighting in this country, and for the far-reaching consequences which may follow such failure. How far these consequences may extend we cannot presume to speculate. Even at the present moment we believe that the stimulus given to genuine enterprise in electric lighting by putting it on the gas footing would be considerable. If that enterprise succeeds, a further stimulus will be given to the application of science to industry which cannot but be important. Indeed, the encouragement of electric lighting at the present moment might be the turning point in the long-continued depression of trade under which the country has lately been suffering. Having regard to the keenness of competition which has now overtaken the long undisputed lead of this country in industrial progress; having regard to the circumstance that England is already distanced by America in the industry of electric lighting; that this may be a step towards leaving to America a permanent lead in the new applications of science; and that America still holds in reserve the resources of the approaching extinction of her debt and the ultimate adoption of free trade, we think the Board of Trade will attach due weight to the importance of giving at this critical stage a fair field to the development of electric lighting enterprise. With these larger considerations the committee are not primarily concerned. As representing the interests vitally affected, the question for the committee is on what terms we can call for or invite capital to the enterprise of public electric lighting. We must keep in view that the electric lighting industry will in any case remain in possession of the smaller and safer field which may be exploited on conditions not involving wayleaves through the streets. The Electric Light Companies will continue in possession of the ship lighting industry, and on land they will be able to conduct electric lighting on a small scale as an expensive luxury for those who are able to pay for it. As to the larger field, if the industry can be worked only on the terms that property, which is the result of private money and enterprise of the undertakers — not consisting of an undertaking built upon land the subject of a concession, but as much their own as the property of an insurance company or telegraph construction company, which has been obliged to apply to Parliament for powers affecting its constitution—is to be taken from them by the local authority without either a fair bargain or an Act of Expropriation by the Legislature of the day, we, as representing those whose capital is proposed to be at risk, feel bound to pronounce the words *non possumus*. We cannot, we dare not, we will not embark our capital on these terms."

ECONOMY IN ELECTRICAL CONDUCTORS.*

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

(Concluded from page 355.)

V. For the purpose of constructing a table to be used for determining the proper current and resistance of conductor per mile to be selected in various cases in order to obtain maximum economy, and for determining the waste that will occur per mile in heating, and the amount of interest on the value of the copper per mile when the current and resistances per mile are employed, let

$$\frac{n\,t}{V} = \tan\phi,$$

then
$$C = \frac{P}{V}(1+\sin\phi) \quad . \; . \; . \; . \; . \; . \quad (11)$$

and
$$r = \frac{V^2}{n\,P} \cdot \frac{\sin\phi}{(1+\sin\phi)^2} \quad . \; . \; . \; . \quad (12)$$

Using these values, the following table (No. 1) has been calculated for V equal to 200 volts and P equal to 20,000 watts, in order to illustrate the way in which the current, sectional area of the conductor, and current-density proper to be used to obtain maximum economy, vary with the length of the line. The first column gives n the number of miles, at the end of which this power is to be furnished if the earth be used as the return. If the earth be not used as the return, then n will be *twice* the distance between the two ends of the line. The second column is $\frac{n\,t}{V}$, where t is taken as (17). The third and fourth columns give ϕ and $\sin\phi$, the fifth and sixth the current C in amperes that should be employed, and the resistance r in legal ohms per mile that should be given to the conductor to obtain maximum economy. Column 7 gives the sectional area A of the conductor in square inches, the resistance of one mile of copper wire of 98 per cent. conductivity at 20° C., one square inch in section, being taken as 0·04378 legal ohm. Column 8 gives D the current density—that is, the number of amperes per square inch. Columns 9 and 10, P_1 the power in watts wasted in heat per mile, and P_2 the watts wasted per mile as interest, including depreciation on the value of the conductor. The last column contains the values of P_3 the total rate of waste in watts per mile.

TABLE I.—To furnish 20,000 watts at the end of n miles.

1	2	3	4	5	6	7	8	9	10	11
n	$\frac{17}{200}n$	ϕ	$\sin\phi$	C	r	A	D	P_1	P_2	P_3

The latter portion of this table has been calculated merely for the purpose of illustrating how the current, sectional area of the conductor, and current-density necessary to be used to obtain maximum economy, vary with the length of the line, and not because anyone would think of attempting to transmit 30 horse-power 50 or 100 miles with a potential difference of only 200 volts at the dynamo.

The problem considered by Sir William Thomson led to the result that in order to obtain maximum economy the area of the conductor depended solely on the current, and was independent of the length of the line, or, in other words, the current-density was a constant. But from the preceding table we see that, *if a given amount of electric power has to be furnished at the end of a line with a given potential difference at the dynamo, maximum economy is obtained, not by keeping the current-density constant, but by making it diminish as the length of the line becomes greater.*

In order to employ this table for other amounts of power to be furnished at the distant end of the line, it is to be observed that since

$$C = \frac{P}{V}(1+\sin\phi) \quad . \; . \; . \; . \quad (13),$$

$$r = \frac{V^2}{nP} \cdot \frac{\sin\phi}{(1+\sin\phi)^2} \quad . \; . \; . \; . \quad (14),$$

and since the sectional area of the conductor

$$A = \frac{0{\cdot}04378\,nP}{V^2} \cdot \frac{(1+\sin\phi)^2}{\sin\phi} \quad (15),$$

it follows that with the same initial potential difference the most economical current to employ is directly proportional to the power to be furnished at the distant end, the most economical resistance per mile to give to the conductor is inversely proportional, and the most economical sectional area directly proportional to the power that has to be furnished at the distant end of the line.

VI. In the construction of telpher lines we use steel rods both to carry the load and to carry the conductor. In order, then, to see how the numbers in Table I. must be altered if steel be used, instead of copper, we must see how the value of t is altered. Now, since

$$t^2 = 67{\cdot}84\,\frac{i \times c \times \rho}{p}$$

where i is the yearly interest, including depreciation, on money invested in conductors, c the value in pounds of a ton of the metal used in making the conductor together with the value of the necessary amount of insulation, ρ the resistance of a wire one mile long and one square inch in section of the material employed in making the conductor, and p the annual cost in pounds of an electric horse-power for the number of hours that power is required. Now, the specific resistance of steel bears to the specific resistance of copper approximately the inverse ratio of the cost per ton of steel to the cost per ton of copper; hence the product $c\,\rho$ for steel will be roughly the same as $c\,\rho$ for copper, and consequently the value of t may, for a rough approximation, be regarded as unaltered. All the columns, therefore, in Table I. will remain roughly the same if steel be used in the place of copper, with the exception of column 7, giving the sectional areas, and column 8, the number of amperes per square inch.

Also all the columns will remain unaltered as long as $\frac{i \times c}{p}$ is constant; for example, no change will be necessary if the yearly interest, including the depreciation, be taken as £10 instead of £15, and if the yearly value of an electric horse-power be also taken as £10 instead of £15.

VII. We may take as an example of the use of the results obtained by this investigation the case of the electric transmission of power from Paris to Creil by M. Deprez. The distance is 37½ miles, and as a wire was used for both the going and return conductors n equals 75; the potential difference at the dynamo V was about 5,600 volts, therefore

$$\tan\phi = \frac{n\,t}{V}$$
$$= 0{\cdot}2278$$

or
$$\phi = 12°\ 50'.$$

Hence, as the power furnished at the distant end of the line, P, was about 30,000 watts.

$$C = 6{\cdot}549 \text{ amperes},$$

and
$$r = 2{\cdot}073 \text{ ohms}$$

give the values of the current and the resistance per mile of the line that should be used to give maximum economy, or since

* Paper read at the Meeting of the Society of Telegraph-Engineers and Electricians, March 12th.

Digitized by Google

the line is ·75 millimetre long, the total resistance should equal 155·5 ohms.

M. Deprez actually used a current of about 7·2 amperes, and the total resistance of his line was 100 ohms. We do not know on what principle he calculated the size to give to his conductor, which was a copper wire five millimetres in diameter, but the current conveyed was at the rate of about 36·6 amperes per square centimetre. The above, however, shows that the most economical current, using 17 for the value of t, would have been at the rate of 47·7 amperes per square centimetre. But as his object was rather to show economy in electric transmission of power, irrespective of first cost, than to show economy in copper used, and as when he began his experiments he was probably not quite sure of the potential difference at which his dynamo would give out electric power, we think that he was quite right in using a thicker conductor than our calculation shows would have produced the minimum total waste.

We have already seen that when we have to supply a given amount of electric power at the end of a certain line, using a given potential difference at the dynamo, the current-density to be employed to obtain maximum economy diminishes as the length of the line increases. Thomson's rule for the current-density is obtained from his equation for maximum economy—

$$C = \frac{t}{r},$$

and the equation

$$A = \frac{0{\cdot}04378}{r}$$

$$\therefore D = \frac{t}{0{\cdot}04378},$$ which is independent of the length of the line.

For t equal to 17 his D equals about 393 amperes per square inch. We see, therefore, that this current-density exceeds that given for all the lengths of line, even for the shortest—0·1 mile or 170 yards—in column 8 of Table I., although in calculating this table the same value was employed for t; that is, the same values were used for the yearly rate of interest, for the price of copper wire per ton, with its necessary insulation, and the same cost per year for an electric horse-power for the number of hours power is required. In order to see whether for any distance, or for any amount of electric-power to be supplied at the end of this distance, it is economical to use so large a current-density as is given by Thomson's rule, we will find an expression for our current density. Dividing the expression given for C in (13) by that for A in (15), we have

$$D = \frac{V}{0{\cdot}04378\,n}\,\frac{sin.\,\phi}{(1 + sin.\,\phi)};$$

hence, as

$$tan.\,\phi = \frac{n\,t}{V},$$

$$D = \frac{V}{0{\cdot}04378} \cdot \frac{t}{n\,t + \sqrt{n^2 t^2 + V^2}} \quad . \quad . \quad . \quad (16)$$

Now this is independent of P, the number of watts to be supplied at the end of the line; hence all the values of D, in column 8, Table I., being smaller than the current-density given by Thomson's formula for maximum economy has nothing to do with the amount of power that is to be supplied. Further, we see that the value of D in (16) can only equal $\frac{t}{0{\cdot}04378}$, the value of D given above by Thomson's formula, when either V is extremely large or n extremely small. Hence we may conclude that *in all problems connected with the electric transmission of power where the maximum potential difference that we may use is fixed for us by the Board of Trade, or otherwise, a smaller current-density than that given by Thomson's formula must be used to obtain maximum economy, and the longer the line the smaller must this current-density be; also, the smaller the maximum potential difference that may be employed, the smaller must the current-density be to obtain maximum economy.*

VIII. We have discussed at some length the conditions of maximum economy when a given amount of power has to be supplied at a given distance with a given potential difference at the dynamo, on account of its wide practical importance; but there are many other practical cases which we have not thought it necessary to discuss in which there is an initial relation connecting C and r. One example may, however, be referred to.

Let there be a level electric railway extending n miles in one direction from the engine-house, on which one train is running requiring P watts to propel it at a uniform speed of v miles per hour. Let the resistance of the conductor conveying the power from the dynamo to the train be r ohms per mile, and let V be the constant potential difference at the dynamo. At a time (τ) reckoned from the time the train is at the engine-house let it be at a distance x miles along the line, then

$$P = C\,(V - C\,x\,r),$$
$$x = v\,\tau,$$
$$d\,x = v\,d\,\tau.$$

When the train is at a distance x the rate of wasting power, in watts, is

$$C^2 x r + n\frac{t^2}{r};$$

therefore the waste, in joules, in a time $d\,\tau$ is

$$\left(C^2\,x\,r + n\frac{t^2}{r}\right) d\,\tau;$$

hence the loss in the whole line n miles long is

$$\frac{1}{v}\int_0^n \left(C^2\,x\,r + n\frac{t^2}{r}\right) d\,x,$$

and maximum economy will be effected by selecting C and r so that this expression is a minimum when C and r are connected by the first equation given above.

IX. Hitherto we have been dealing with a conductor giving off power only at one point—either at its end, or, as in the last problem, at a point the position of which varies from time to time; but in telpherage, and in many systems of electric lighting and transmission of power, we have to deal with a conductor giving off in every mile the same amount of electric energy; which, bear in mind, does not mean giving off the same amount of current per mile, since there is a diminishing potential difference as we proceed along the conductor from the dynamo. This problem we deal more fully with in another paper. But if we suppose that an independent conductor takes the required supply of energy to every short length of line—that is, if a number of feeders are employed—we can at once use the results that we have already obtained to determine the most economical amount of copper to employ.

Having determined the most economical size of separate conductor to convey the power to each point of the line of distribution, we may for practical purposes imagine all the conductors connected together metallically so as to form a tapered conductor. As, however—if we imagine such a metallic joining together of the separate conductors—currents will flow through the connections, because the potentials at a point where a connection is going to be made differ from one another in the various conductors, it follows that a conductor of the aggregate section of all the small conductors at every place will not be as economical as would be a conductor whose section at every place was independently determined from the considerations which are given by us in our other paper. However, taking the section of the tapered conductor to be equal to the sum of the sections of the separate conductors which distribute the energy with maximum economy, we find that the following is the result:—

Let the section of a conductor to transmit with maximum economy P watts n miles with a given potential difference be called

$$P f(n);$$

then

$$\int_x^{x_1} P f(x)\,d\,x$$

is the aggregate section at a point x miles from the dynamo when the end of the line is x_1 miles from the dynamo. It is easy to obtain an exact integral, using (15) for $P f(x)$, but we have preferred to integrate from a curve giving the value of A or $P f(x)$ when P is 20,000 in column 7 of Table I.

Digitized by Google

In this way we have, for illustration, calculated Table II., which gives the most economical sectional area, in square inches, at the end of each mile when the conductor *tapers* according to the law just mentioned; it is calculated for a potential difference of 200 volts at the engine house, and for a power of 5,000 watts given off in every mile. The four horizontal rows give the sectional area, in square inches, of the tapered conductor at the end of each mile, when the total length of the conductor is respectively 3, 5, 8, and 10 miles.

TABLE II.

Total Length of Conductor from Engine House, in miles.	Area, in square inches, of the Tapering Conductor at the end of										
	0	1	2	3	4	5	6	7	8	9	10 miles
3	0·24	0·17	0·09	0							
5	0 47	0·40	0·32	0·23	0·12	0					
8	0·94	0·88	0·79	0·70	0·60	0·47	0·33	0·18	0		
10	1·35	1·28	1·20	1·11	1·00	0·88	0·74	0 58	0·41	0·21	0

Table III. gives the current, in amperes, flowing through the conductor at the end of each mile in each of the various cases described above.

TABLE III.

Total Length of Conductor from Engine House, in miles.	Current, in amperes, flowing through the Tapering Conductor at the end of										
	0	1	2	3	4	5	6	7	8	9	10 miles
3	85·7	59 6	31·4	0							
5	151·8	125·7	97·5	66·1	34·0	0					
8	262·9	236·8	208·6	177·2	145·1	111·1	75·5	38·4	0		
10	343·2	317·1	288·9	257·5	225·4	191·4	155·8	118·7	80·3	40·7	0

Table IV. gives the current-density at the end of each mile in each of the cases described above.

TABLE IV.

Total Length of Conductor from Engine House, in miles.	Current Density in the Tapering Conductor at the end of										
	0	1	2	3	4	5	6	7	8	9	10 miles
3	357·2	350·5	348·9	0							
5	322·9	314·2	304·7	287·4	283·2	0					
8	279·7	269·1	264·1	253·1	241·8	236·3	228·8	213·3	0		
10	254·2	247·7	240·7	232·0	225·4	217·5	210·5	204·6	195·8	193·8	0

Here again, then, the current-density proper to be used to obtain maximum economy is not constant. It not only diminishes as we go further along the tapered conductor, but at any one point is the less the greater the total length of the line.

A THERMOPILE AND GALVANOMETER COMBINED.*

BY PROF. GEORGE FORBES, M.A.

The author has lately made use of a special form of thermopile and galvanometer combined, which is very sensitive for the measurement of radiation. The apparatus is especially suitable for use as a line thermopile.

The first experiments were made with two half tubes, one of antimony the other of bismuth, soldered together so as to make a short tube about 2 cm. external diameter, the walls being 2 mm. thick, and the length of tube about 2 or 2½ cm. The sides of the tube where the junction of the metals occurs was then filed flat, so as to present a thin wall to receive the radiations and to enable it to rise in temperature more rapidly, and also more uniformly throughout the thickness of this wall. This tube was lamp-blacked. A Thomson mirror and magnets (by J. White, of Glasgow), in its usual brass cell, but with an insulated coating, was then inserted in the tube, and the whole apparatus mounted inside a brass cube with a brass cone at one side to throw the radiations upon one junction, and with a circular hole facing the mirror. This apparatus, when properly adjusted with a lamp and scale was found to be very sensitive. It had been the intention of the author to use a telescope in place of a lamp, but the radiations of the lamp were found to give rise to no inconvenience.

Let us compare the probable sensitiveness of this instrument, say, with a line-thermopile of the ordinary construction of 20 pairs, forming a line of the same length as the tube, the double length of a pair of antimony and bismuth in the line-thermopile being equal to the circumference of the tube. Let E be the E.M.F. of one junction, and let R be the resistance of one pair in the line-thermopile, and let R′ be the resistance of the galvanometer used with the line-thermopile. The total resistance of the line-thermopile is 20R, and that of the tubular one is $\frac{R}{20}$, and the currents in the line and tubular thermopiles respectively are $\frac{20\,E}{20\,R+R'}$ and $\frac{20\,E}{R}$. If the galvanometer were specially constructed to match the line thermopile R′ would be made equal to 20 R, and the current would be $\frac{E}{2}$, or one-fortieth of the current in the tubular thermopile and galvanometer combined. Thus it would require forty turns of wire in the low resistance galvanometer, if these coils occupied the same space as the metal of the tubular thermopile, to equal the sensitiveness of the latter, and a larger number if it occupied a greater space. On the whole, it seems probable that by specially designing a galvanometer to match the line thermopile the arrangement would be about as sensitive as the new instrument in the form hitherto described, but the simplicity and cheapness of construction of the latter commends it.

The next apparatus was made according to the following instructions :—

Take a wedge whose distance from the apex to the base is about 6 cm., the base of the triangular section of the wedge being about 3 cm., and the width of the wedge 6 cm. The wedge is half of antimony and half of bismuth, the division being made by the medial plane perpendicular to the three rectangular faces of the wedge cut off the apex of the wedge by a plane parallel to the base of the wedge, and exposing a surface of 1½ cm. width. This is the surface which receives the radiations, and it is lamp-blacked. A hole about 1 cm. diameter is now drilled (or it is better to file it out before the two metals are soldered together) through the two sides of the wedge, so as to leave only a thin wall along the junction of the metals at the surface which receives the radiations. A Thomson cell with suspended mirror and magnet is inserted in this hole and the instrument is complete, and ready to be placed inside the brass box with cone already described.

The resistance of this cell is very low, and its sensitiveness thereby increased. Moreover, this type has a great advantage in the fact that the mass of metal acts as a damper upon the vibrations of the magnet, and so we have a dead-beat instrument.

The diameter of the cone to receive radiations at its mouth was 5 cm. A candle at a distance of 30 cm. from the mouth of the cone gave a deflection of 52 divisions, a reading being easily made correct to one division. A duplex lamp burning paraffin oil at a distance of 1½ metres gave a deflection of 60 divisions.

The author takes this opportunity to describe a method of carrying the delicate Thomson cells without danger of breaking the silk fibre suspension. The cell consists externally of a brass tube. A horse-shoe magnet is obtained with the distance between its legs small compared with the diameter of the above-mentioned tube. The tube is so placed as to rest on the inner edges of the legs of the magnet, with the mirror over the poles of the magnet, the mirror magnets having their poles over poles of opposite name of the horse-shoe magnet,

* Abstract of a Paper read before the Royal Society.

Digitized by Google

and with the silk fibre next to the magnet. The mutual magnetic attraction takes the tension off the silk fibre and holds the mirror fixed in position, and the fibre cannot be broken by a blow given to the apparatus.

CORRESPONDENCE.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the etiquette of journalism which prevents your courteous reviewer from revealing his identity does not prevent him from explaining his reasons for differing from the corrections which I have given to his remarks, I presume that the same useful etiquette will not debar him from reading my reasons for adhering to my corrections. As he has gracefully acknowledged his error in respect of the number 746, I may pass over without serious protest his irrelevant excuse that it was not until after Lord Rayleigh's investigations that we could rely upon the substantial correctness of horse-powers calculated from observations of volts and amperes by use of the denominator 746. That latter statement I do not dispute, but once more repeat that it has nothing whatever to do with the original and incorrect statement of my reviewer; the right figure should be 736.

I must, however, seriously protest against the rest of your reviewer's letter on page 353, in which he persists in using the term critical speed in another sense than that in which it is used by all the authorities who have written on the subject. I pointed out on page 331—though apparently all too briefly for the clear apprehension of the matter—that the definition of the critical speed of self-regulation must not be confused with the speed at which a self-exciting dynamo is just able to excite itself (with given resistances in its circuits). Your reviewer persists that the term "critical speed" is correct for the latter, not for the former. I beg most politely, yet firmly, to persist that the term critical speed, as used consistently by me, by M. Marcel Deprez, by Professors Ayrton and Perry, and I believe by every competent writer on the question of compound winding, is used in the sense of the speed that is critical for self-regulation, and *not* in the sense of the speed that is the limit for self-excitement. Of course, if your reviewer is right, then no machine that is not purely self-exciting can have a critical speed, be it motor or generator. It follows, as a matter of course, from the definition, if your reviewer's definition is right; but, unfortunately it is not! Give a definition a wrong turn, then hang the writer who dares to write the right one. This persistent perversity of using a wrong definition has led your reviewer in his defence into a strangely wrong-headed argument. He seriously argues about a sentence of mine as if the machines I mentioned in it as having permanent magnetism or separate excitement were not self-regulating machines at all, whereas I mentioned machines having such auxiliary excitement as instances of machines having certain critical speeds for self-regulation, and yet not depending on any limiting speed before their magnets are excited. Your correspondent seizes upon my words, oblivious that the whole thing relates to self-regulation, and jumps to the conclusion that I referred to certain magneto or separately excited machines that are not self-regulating, and which have no critical speed either in his incorrect sense or in the correct sense of the word. Hence follows all his muddle about the want of parallelism between a descending curve of potential and an ascending line of resistance, and his triumphant proof that the descending curve cannot possibly be parallel to the ascending line. Of course, it cannot; and it has absolutely nothing to do with the point at issue, simply because the descending curve about which he talks is not the curve of a self-regulating machine at all! I have shown on page 372 of my book that for a pure self-exciting series-wound dynamo there is no such thing as a critical speed, independent, like the true critical speed of a self-regulating dynamo, of the resistance of the external circuit. I have shown, on p. 382, how, at the critical speed, the characteristic curve of the self-regulating (constant-potential) dynamo (whether its initial excitement be due to the magneto machine or to the separately excited coils combined with the series coils) not only is but must be approximately parallel to the sloping line that represents (by the tangent of the angle) the armature resistance. This is a hard saying; it has "stumbled" your reviewer; it will stumble him again if he sets out with the wrong definition, even though it is carefully explained with the help of two illustrative cuts on pp. 382 and 383, and the similar case for constant-current machines by a third cut on p. 385 of my book. I know that my book is dull and tedious and long-winded, and I can well pardon a reviewer who should skip a little when he reached the 382nd page. Only he should not afterwards turn round and beg to be told how a curve (and the mathematical term "curve" includes those whose equations are *of the first degree*) can be approximately parallel to a given straight line. If he will ask me to show him how the curved sole of my boot can be placed approximately parallel to the horizontal plane, I shall be happy to oblige him.—Yours, &c., SILVANUS P. THOMPSON.

Finsbury Technical College, March 14th, 1886.

P.S.—About the motors. Your reviewer does not understand that *if* a constant current is driven through a motor the potentials at the terminals of the motor will vary with its speed, and may be made, therefore, to regulate that speed by use of a shunt winding properly proportioned to the case. He says: "If my (that is to say, his own) views on critical speed be right, special, and probably complicated, regulating apparatus will have to be added to each motor." Exactly so. I have no doubt of it. S. P. T.

SECONDARY BATTERY INDICATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have carefully read Mr. Sellon's specification, as given in his letter in your last issue, and must say, with all due deference to that gentleman's valuable inventions, that I fail to see how it anticipates the perfected arrangement patented by Mr. Parker in 1884. In the first place, ascertaining the state of the charge in secondary cells by measuring the specific gravity of the liquid had, we all know, been suggested and practised before the date of Mr. Sellon's patent. In the second place, the design shown in Figs. 1 and 2, and fully described by Mr. Kent, *would not work*, because any change in the density of the liquid, sufficient to cause the bulb to move *at all*, would send it right to the top or the bottom, whichever it happened to be, as there is nothing to stop it, unless the "*fine* wire of glass or of platinum" is supposed to displace so much of the solution that it would act like an ordinary hydrometer.

If the latter be the case, then the accuracy of the measurements indicated must depend upon the liquid being maintained always at an exact level in the cell, and I do not think there are many "gardeners" who could be depended upon to keep this level always constant.

Mr. Sellon's arrangement, shown in Figs. 3 and 4, also depends entirely upon the level of the liquid in the cell, and I feel sure the "gardener" would be too "heavy-handed" to adjust this always—even to one point of decimals—and a variation of one-tenth of an inch might cause much overcharging.

Mr. Parker's claim is for a simple form of hydrometer, which is not influenced by changes in the level of the liquid in the cell, and correctly indicates the density, so long as the bulb (which is of considerable size, in order to make the indications very accurate) is entirely below the surface of the solution. The weight is increased or diminished, as the arm carrying the balance weight forms a more or less acute angle with the perpendicular.

Mr. Sellon could obtain a similar, but I think less accurate effect—owing to friction, &c.—by using what is called a "fusee," instead of the pulley, in his "wheel-barometer" arrangement; but this would make it practically the same as what Mr. Parker claims.—Yours, &c., P. BEDFORD ELWELL.

THE WEST COAST OF AFRICA CABLE.

Considering the enormous capital invested and the commercial interests involved in Submarine Telegraph Cables belonging to this country they have, in our opinion, always been very inadequately represented at Westminster. The debate on the WEST AFRICAN CABLE CONTRACT last Friday week revealed the fact that what little representation they enjoyed in the old Parliament has been extinguished by the new electorate. Not property, not responsibility, not knowledge, but chiefly numbers now command a voice in the national deliberations; and unless the representatives of capital invested in submarine cables happen also to be men who can shout with the multitude, their interests may remain for the future undefended. This is greatly to be regretted, for the present composition of the House of Commons has already shown itself eager to assail any and every kind of proprietary right, and to regard no form of contract too sacred to be cancelled. We have seen in recent years how Cable Companies' affairs have suffered at the hands of responsible Ministers; how they will be handled by irresponsible legislators of the new order was sufficiently indicated the other evening.

The occasion was a very slight one indeed; but it was made the most of, and occupied the House for a couple of hours or more, furnishing material for many highly characteristic speeches. Ever since the troubles in South Africa the Government have recognised the necessity for a cable—or rather a series of cable sections—extending southwards along the West Coast of Africa, and placing our isolated colonies in that quarter of the world in direct communication with the home country The Brazilian Snbmarine Telegraph Company as far back as June, 1883, had offered to lay these cables, and some twelve months after tenders were invited by the Government in power, and after much negotiation, both by the Liberal Administration and their successors, the latter were able to make a bargain which everyone knows was a good one for the Government, whatever it may have been for the tendering company. A subsidy was in any case necessary for a term of years, as no cable could at present be worked there at a profit solely from commercial or private traffic. The amount of the subsidy was therefore alone in question; and the late Chancellor of the Exchequer managed to secure the cables for an annual grant vastly below the highest tender, and about £10,000 below that of the next lowest. This, too, with a perfectly sound and responsible company. The contract, which was concluded in January last, had to be submitted to Parliament for ratification; and it was this that gave Mr. HENNIKER HEATON, who represents the city of Canterbury, the opportunity he desired to make a gross personal attack upon the party or parties he was pleased to style "John Pender and Company." What he called his "mistrust" of this personage led him into making the wildest accusations of bad faith and dishonesty, without apparently the least ground for them, at all events in regard to this particular transaction, which Ministers and ex-Ministers alike described as perfectly straightforward and honest. Not often has the privilege of attacking in Parliament an absent man been so grossly abused. The member for Canterbury does not appear to know anything of cable construction, nor of England's needs in respect to national cable laying. He simply "suspected" and "mistrusted" the parties concerned, and declared he would prove them "dishonest" if an opportunity were afforded him in private. Such are the amenities of parliamentary life, which we have heard of in some of the Colonies, but which are a novel experience for us. We should like to know what the citizens of ancient Canterbury think of this new type of Conservatism.

The one tangible bit of ground for Mr. HEATON'S insinuations was the assertion that at the time the contract was signed with one company the cable had already been laid by another company. It was promptly explained that only a small section—a sixth of the whole—had been submerged; and that the transfer of the contract from the INDIA RUBBER COMPANY, who first undertook it at a high figure, was due to an agreement with the EASTERN TELEGRAPH COMPANY, who were prepared to carry it out at a much lower figure. But this was enough for the free lances of the smoke room, who forthwith, headed by Mr. LABOUCHERE, continued the fight on the highest moral grounds. It was shocking that all the facts, though utterly irrelevant, had not appeared on the face of the contract; it was especially monstrous that the EASTERN TELEGRAPH COMPANY, who possessed a lot of cables already, should own any more; and to clinch matters the payment of subsidies was radically bad in principle. The hon. member for Northampton confessedly knew less about the subject than the hon. member for Canterbury; but principles are quite above knowledge and far superior to good manners. Just as the village loafer in *Punch* salutes a stranger with "Let's heave a brick at him," so Mr. LABOUCHERE and his following make an ugly rush at this innocent contract, partly no doubt because they have a personal grudge against the contractor, but chiefly because they are grossly ignorant of the whole subject. That we are not exaggerating the facts, or needlessly protesting against the predatory spirit which actuated the debate, will be evident by a reference to the speech of Mr. ILLINGWORTH. This

Digitized by Google

gentleman objected to the smallness of the sum—more than a fourth part of the whole—to be contributed by the colonies towards the annual subsidy. "It was," he said, "the large owners of land in those colonies that were chiefly interested, and it was to make them a great landed aristocracy that the late wars were waged; therefore, they ought to contribute a great deal more than £5,000 of the £19,000 required." The member for Bradford evidently does not know where the West African colonists are or what they are; but he thinks they are landowners, and that is enough for him.

Men who are betrayed into such follies as these by prejudice or spite are not likely to draw nice distinctions between one class of property and another. We do not suppose that Mr. ILLINGWORTH confessed himself wrong when presently informed that West African colonists for the most part do not own so much as three acres and a cow. They own something plainly, or they could not pay £5,000 a year; and if £5,000, why not eight or ten thousand? So with cable property generally. Evidently it is being regarded with jealous eyes by a certain section of politicians nowadays; and to protect itself against these, as well as against the more excusable assaults of foreign governments, who not unnaturally view our supremacy with irritation, some active steps ought to be taken to secure a better representation in the British House of Commons. Failing direct representation, surely there are shareholders in that assembly who would willingly become the mouthpiece of the companies on occasions like the one on which we have been commenting. If mutual jealousies prevent any joint action of the kind for their common safety, then the companies must expect to see themselves separately assailed and ruined in detail.

EFFICIENCY TESTS OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The difficulties in transmission-dynamometer tests, especially with engines which are not free from sudden jerks (in my case a gas engine), led me some time ago to derive the following method for determining the power transmitted to a dynamo:—

Instead of driving the dynamo to be tested directly by the engine, it is coupled to an electric motor which receives its current from a dynamo driven by the steam or gas engine. The efficiency of the electric motor being determined previously by means of a dynamometric brake (this being comparatively much more accurate and easy than a transmission dynamometer test), we have at once the power applied to the dynamo by measuring the current in the motor. Of course the greater part of the current in the motor can be supplied by the dynamo under test, as indicated by Dr. Hopkinson in your last issue. This more intricate arrangement would only be useful, however, in testing large dynamos, when there is no sufficient current for the motor otherwise.

If we would admit that magnetic and other friction is the same with or without current in armature (as is admitted in Hopkinson's test), then the commercial efficiency of a dynamo may be tested, as I indicated, *without any mechanical power measurement, only by measuring elec'ric quantities.*

Indeed, the loss in friction is determined by the difference in electric work supplied to the electric motor running at a given speed, when coupled to the dynamo (without current in armature) or disconnected from the same.

By inserting this letter in your next issue, you will oblige —Yours, &c., C. L. R. E. MENGES.

The Hague, Holland, 15th March, 1886.

MISTAKES IN ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your previous number there is an article by Mr. von Tunzelmann on "Mistakes in Electricity." As I do not agree with him about that which he calls mistakes, I should like to understand more clearly his meaning on one or two points which are of vital importance at the present stage of electrical science. I therefore make the following quotations from his article, page 347:—

"The student will have learned already, in the study of frictional electricity, that electricity can neither be generated nor destroyed. . . . We see that the motion of electricity is like that of a material fluid, an analogy which is often of great value in explaining electrical phenomena; but in making use of it the teacher should carefully guard against allowing the learner to suppose that in the electric current there really exists anything like an actual material fluid."

This extract makes it very plain that Mr. von Tunzelmann does not believe that electricity is any kind of matter whatever. But the following paragraph of his seems to convey the idea that electricity is a something, and not a mere nonentity. He states, "In the development of electricity, either by frictional apparatus or by a voltaic battery, the electromotive force is produced in the same way—viz., by the contact of two dissimilar substances; but in the first case, the requisite energy is obtained from mechanical sources." According to this paragraph, electricity is *a force*, and it is *energy*. Does Mr. von. Tunzelmann agree that this is his meaning?—Yours, &c., JAMES JOHNSTONE.

THE ELECTRIC LIGHT AT THE PRINCE'S THEATRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have great pleasure in handing you the following report of the second year's work of the installation at the Prince's Theatre, and trust you will find space for it in your journal at an early date.—Yours, &c., ERNEST L. BERRY.

This installation has now completed its second year of running, having run for two years without a breakdown or any mishap in the light. The plant consists of a 12 horse-power Clark gas engine, manufactured by Messrs. L. Sterne and Co., a Siemens S D_1 dynamo, and storage cells by the E. P. S. Co. There are 350 Swan lamps, 108 volts, 16 candle-power.

The engine has during the year run for 2,559 hours, and has not given the slightest trouble either in starting or when at work. It was overhauled in December last, and the water jacket cleared of its deposit of lime. The only renewal we have had for the engine has been a few piston rings. Besides doing its ordinary work of driving the dynamo it is used frequently for pumping water into the tanks to supply the hydraulic fire proof curtain and lift.

In regard to the E.P.S. cells, as a difficulty was experienced in the leaking of the teak boxes, it was decided while making a change to put in some of the new cells containing all the latest improvements, and supplied in glass boxes; and of these new cells, although put to very severe tests, not one has failed. We have repacked several of the teak boxes with new positive plates and lead connections, and these have answered admirably. We had up to 16th of January of this year one cell of the old type, which has been in constant work for two years, and has not on any occasion failed. It has not been repaired, or seen to in any way. It is eviden', therefore, that there is no reason why, when carefully made, the accumulators should not last throughout this length of time without being in any way renewed, and it is expected that this result will be attained with the later cells put down.

The dynamo has run very well. A new commutator was put on in December last; the old one during its run was turned up three times. There have been 10 pairs of brushes used during the 12 months. The lamps show a somewhat better average than last year, on account of our being able to get 30 of the broken-looped ones repaired. We have renewed during the year 78 lamps from the following causes—38 by carbons, 10 by accident, and 30 by loops breaking off.

The cause of so many loops being broken off is through using 18 lamps to light up a scene of "The Great Pink Pearl" for six months, the constant moving about breaking the loops, and occasionally one got broken by a fall. There are several

Digitized by Google

lamps that were originally put up still burning, having run for 2,500 hours. Subjoined is an abbreviated account of the working expenses, and also the repairs and renewals for the year :—

WORKING EXPENSES.

Electrician and assistant	£239	5	6
Gas	188	4	0
Lamps	14	5	0
Oils for engine, shafting, dynamo, and pumps	10	0	0
Waste	1	12	6
10 pairs brushes	2	10	0
Lamp shades		15	0
Sundries, &c.	4	0	0
	£460	12	0

REPAIRS AND RENEWALS.

Dynamo	£12	9	0
Engine	7	0	0
Accumulators	187	9	6
Belts	11	5	4
	£218	3	10

Total for working	£460	12	0
Total for repairs, &c.	218	3	10
	£678	15	10
Previous year	452	10	0
Grand total for 2 years' working...	£1,131	5	10

Subjoined is Mr. Bruce's certificate as to the working of the installation :—

"I have great pleasure in again certifying to the successful working of the electric lighting at the Prince's Theatre. It has been in operation for more than two years, and during the whole of that period it has not failed on any one occasion. I am also greatly pleased at its adaptability for stage purposes; the lighting of the stage during one act of "The Great Pink Pearl" was most successful and original, and I hope before long to still further try its uses for stage effects.

"EDGAR BRUCE.

"The Prince's Theatre, March 11, 1886."

TELEPHONIC LITIGATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Our attention has been called to a paragraph in your issue of the 26th ult. with regard to certain proceedings brought by the United Telephone Company against Mr. Fleming, of Liverpool, for alleged infringements of Bell's and Edison's telephone patents, in which you state that the company has withdrawn from the attack so far as Prof. Silvanus Thompson's instruments are concerned.

The action brought against Mr. Fleming had nothing whatever to do with Prof. Silvanus Thompson or with his telephone. The action was brought in respect of certain Bell telephones and carbon transmittters, which certainly were not supplied by the New Telephone Company. The United Telephone Company have withdrawn from nothing, and the action against Mr. Fleming will proceed upon the lines always intended.—Yours, &c.,

WATERHOUSE, WINTERBOTHAM, AND HARRISON.

1, New-court, Carey-street, Lincoln's Inn, W.C.
March 17, 1886.

HOLBORN VIADUCT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : May I ask Mr. Hartnell if the Edison lamps now supplied to consumers on the Holborn Viaduct are a fair sample of those he speaks of having burned so long a time ? If such is a fact I am not surprised at their long life. My attention was drawn towards a window burning these lamps, the weakness of which caused me to "inquire within." I found the lamps inside no better than those in the window. The consumer was not at all satisfied with the light, and wished it out. He had been a strong advocate of electric light, and I believe was a large holder of stock in some company, but whose name he did not mention. He asked me the cause of the lamps burning so poorly. Being compelled to dig out a living by this business, which, through these very defects in other people's instruments, only enables me to live in a garret until the public are enlightened as to the causes of such imperfection, I went at once to inform the managing engineer to put on a little more steam, as his customers were becoming disgusted with the light, when, for my interest and that of the profession, they should be encouraging. I was refused admittance (perhaps from fear of my carrying off one of the company's dynamos). I feel safe in saying that until the electrical engineer tries to help the public to see it by explaining clearly the causes that can produce such effects, domestic lighting will progress with but little speed.—Yours, &c., BONEO.

YET ANOTHER DISCOVERY!

TO THE EDITOR OF THE ELECTRICIAN.

SIR : It appears to me that the votaries of electrical science are happily chosen to render the duties of the medical man less and less arduous ; and, by your leave, I shall endeavour to explain an idea—I will not say a grand idea, because *real* genius is modest—which, if acted upon, cannot fail to be of use to that worthy soother of pain.

We have the telegraph to communicate with our correspondents through, and we have the telephone by which we can give our wives due notice that Jones is coming to dine with us. Why, then—coming to another very important requirement—why should not the medical man be able to ascertain the temperature of his fever-stricken patient, as well as give his instructions as to treatment, *by wire* from his very consulting room ? This is a question which put itself very forcibly to me the other day while I was stretched out in my long chair pensively smoking a cigar. The solution came as an inspiration, and I felt highly elated. (I wonder if Sir William felt like that when the "mirror" flashed across his great mind ?) For the benefit of mankind and the doctors I give that solution.

A well-insulated wire must be laid from the consulting room to the patient's house. At one end a suitable metallic handle soldered to the line wire must be arranged so that the patient can place it under his arm, as he would a thermometer, when required. At the other end a very sensitive galvanometer, the line wire joined to one terminal and a wire leading to earth joined to the other terminal. I may here remark that this idea is especially applicable to fever-laden parts of the globe, where fever is the rule and not the exception. We will say, for example, East or West Africa. Earthing *there* by means of the gas pipe is not always possible, so the medico's best plan to make sure of good earth will be to solder the lead to a copper plate and bury that plate in the nearest swamp, for it is pretty certain that there is a swamp not far off. For the sake of economy the same wire can, by switching, be used for telephonic conversations and for the temperature-reading idea ; so we will suppose the arrangement complete.

Medico rings the bell, and is answered by the patient's nurse —usually a nigger in Africa.

Medico : "Where is your master ?"

Sambo : "In bed, saar."

Medico : "Switch over and put the handle under his arm for three minutes."

Sambo : "All right, saar."

It is done, and the medical man observes a very *slight* deflection of his galvanometer needle.

"Hum !" mutters he, "fever still high, 104°."

Three minutes elapse. He rings. Sambo answers.

Medico : "Tell your master to take another Dover's powder, and pile on some more blankets. I shall ring again in two hours."

Sambo : "Right, saar."

Two hours, during which time the medical man has been comfortably seated in his arm-chair listening to the pour-

Digitized by Google

ing rain outside, and thanking "his stars" that he has *now* no need to expose himself to it; the two hours elapse. Preliminaries are gone through as before, and when the handle is placed under the patient's arm the deflection is considerably *larger*. "Bravo!" exclaims Medico, "temperature gone down to 100 deg.!"

He switches over and rings.

Sambo: "Yes, saar."

Medico: "Your master is perspiring, isn't he?"

Sambo: "Yes, saar."

Medico: "Then tell him to take fifteen grains of quinine at once."

Sambo: "Fifteen grains; all right saar."

Medico: "I will ring again in two hours."

Need I explain that when the body is hot and dry with fever the galvanometer needle will be deflected only slightly, and that when it is damp with the thrice welcome beads of perspiration, the needle will be deflected considerably more? And cannot a doctor have his galvanometer scale so arranged that it will be easy for him to arrive at the temperature of the distant patient's body by those deflections?

Sensible persons suffering from fever invariably remain in bed until it has left them. Therefore, the medico can, after a little experience, make out a simple table of "In Bed Deflections," thus:—

Hot, dry Skin.			Cool, moist Skin.		
Deflection.		Temp.	Deflection.		Temp.
17	=	103°	26	=	99·5°
and so on.			and so on.		

But there are some people who will sit muffled up in an arm-chair with their slippered feet upon the carpet. In this case a table of "Feet on the Carpet Deflections" will be necessary.

Example:—

Dry.	Moist.
29 = 103°	37 = 99·5°
and so on.	and so on.

And if the patient has no carpet upon the floor, another table, headed "Feet on the Bare Floor Deflections," is called for.

Example:—

Dry.	Moist.
41 = 103°	52 = 99·5°
and so on.	and so on.

The medical man will see that the less insulating substance there is between his patient and the foundation of the house the greater will be the deflections, so he must always ask Sambo where "massa" is before taking the temperature. He will then know exactly which series of deflections to hit upon.

Here, then, is another drop of nectar for the doctor's fast-filling cup! If he avails himself of it, it will bring him personal comforts long, long given up as unattainable; it will serve as food for reflection; it will bring wondering myriads to his door, and soon he will be looked upon as an exalted performer of miracles! And, furthermore, Sir, the modest aim of one who prefers the doctor's room to his company will have secured its moral bull's-eye!—Yours, &c.

Zanzibar, February, 1886. NORMAL TEMP.

[We are always, or nearly always, glad to hear from our friends abroad; but when it comes to printing their letters we do wish they would call to mind that proverb of their native land which says, Brevity is the soul of wit.—ED. *Electrician.*]

RELATIONS OF SURFACE-RESISTANCE AT ELECTRODES TO VARIOUS ELECRICAL PHENOMENA.*

BY G. GORE, LL.D., F.R.S.

In some experiments described in a paper on "Evidence Respecting the Reality of 'Transfer-resistance' in Electrolytic Cells," read before the Birmingham Philosophical Society, January 21, 1886, I found that when a current of voltaic electricity was passed from dilute nitric or sulphuric acid, or strong nitric acid, into the surface of a thin platinum bottle used as a cathode, the temperature of the bottle suddenly rose, notwithstanding that certain amounts of heat must have been absorbed by the copious liberation of hydrogen which occurred, and by that substance assuming the gaseous state, each at the surface of the bottle; and I further found that this rise of temperature was not due to heat produced by ordinary conduction-resistance of the bottle or of the liquid, nor to resistance of any kind at the anode, and that it was due to some influence other than that of chemical change, at the surfaces of mutual contact of the liquid and bottle; and further, that it varied in quantity directly as the amount of "resistance" to the passage of the current into the surface of the bottle. I also found similar thermal effects of "resistance" at the surface of the bottle, when the latter was used as an anode.

In a previous investigation on "transfer-resistance" (*Proc.* Royal Soc., Vol. 38, p. 209), I also found "that a species of electric resistance distinct from that of polarisation and of ordinary conduction-resistance, varying greatly in amount in different cases, exists at the surfaces of mutual contact of metals and liquids in electrolytic and voltaic cells. That this resistance varies largely in amount with different metals in the same solution, and with the same metal in different solutions," "and is usually small with easily corrodible metals which form readily soluble salts, and large with those which are not corroded," and "that the same voltaic current was resisted in different degrees by every different metal when employed as an anode, and when used as a cathode," "and that the resistance at the anode was usually smaller than that at the cathode," and "that by rise of temperature, 'transfer-resistance' was usually considerably reduced." This "transfer-resistance" differs essentially from electric potential, because it is incapable of producing a current.

The present experiments were made for the purpose of examining some relations of this "surface-resistance" to various electrical phenomena. I call it "surface-resistance" in the present case, because in consequence of omission of stirring, it includes other forms of resistance besides that of "transfer" at the surfaces of mutual contact of the metals and liquids employed.

First.—In cases of thermo-electric currents produced by heating the junction of a metal and electrolyte. We know that when heat is applied to one of the two ends of a piece of non-corrodible metal in contact with opposite parts of an electrolyte, an electric current is usually produced, and we infer from the principle of conservation of energy that when such a current occurs, heat is absorbed and disappears at or near the heated junction, and is converted into and produces the current.

In order to determine whether the relative amounts of "surface-resistance" at the junctions of such a thermo-couple vary with temperature, and also whether the direction of current produced by such a couple is influenced by the relative total amounts of such "resistance" in the two directions in the circuit, I made the following experiments:—

The liquids employed were dilute sulphuric and nitric acids, each being composed of one volume of strong acid and ten volumes of water; and the electrodes were two perfectly similar sheets of platinum, each having a total immersed area of surface of about 24·0 sq. cm.

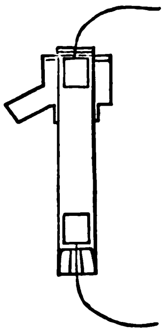
The thermo-electric apparatus consisted of a vertical glass tube, open at its upper end, 19·0 cm. high, and 3·0 cm. internal diameter (see sketch on next page). One of the platinum plates was suspended vertically in the upper end of the tube by means of a platinum wire; and the other, welded to a stout platinum wire, was supported vertically in the lower end by passing a wire through a cork fixed in a hole in a vulcanised india rubber bung which closed the end of the tube. The two plates were 9·0 cm. apart. The glass tube was nearly filled with the acid liquid; its upper end was surrounded by a water bath, the water in which was heated by applying a flame to a projecting arm of the bath. The bulb of a thermometer was immersed in the acid liquid near the upper plate; and the wires from the plates were attached to a dead-beat D'Arsonval

* Read before the Birmingham Philosophical Society, Jan. 21. [In our issue of Feb. 19 a paper on "Evidence respecting the Reality of Transfer-Resistance in Electrolytic Cells" was wrongly stated to have been read before the Royal Society; it should have been the Birmingham Society.]

Digitized by Google

galvanometer. The liquids were not stirred during the experiments.

With the lower plate at 14° C., and the upper one at 95° C., in the dilute nitric acid, a thermo-electric current of about ·00004 ampere was produced. At the same temperature, in the dilute sulphuric acid, the strength of current produced was about 00001 ampere. The current flowed from the cold plate through the liquid to the hot one in each case. As platinum is a thermo electric positive substance, though in a feeble degree, in metallic couples, these results indicate that both these liquids were thermo-electro-positive, and much more strongly so than platinum.



The electromotive forces of these couples during a state of balanced current were measured by means of a modified form of Poggendorff's method, and the values found were as follows: —With the plates at 14° and 95° C, in the dilute nitric acid, ·418 volt.; in the dilute sulphuric acid, ·282 volt.; and in a mixture of one volume of hydrochloric acid and ten of water, ·208 volt.

The amounts of "surface-resistance" were also measured by using a rheostat as a slide-wire bridge; the same electrodes, with the same amounts of immersed surface, being employed as were used in the thermo electric experiments. The electrodes faced each other at about 5·0 cm. apart in the respective liquids in a glass cup, the one which was positive in the thermo-couple being used as the anode; and the strengths of current employed were the same as the thermo-electric ones, because I have found that an alteration of strength of current affects the amount of "transfer-resistance." One terminal of a Thomson's reflecting galvanometer of 3,045 ohms resistance, was connected with the slider, and the other connected, first to the anode (or cathode), and then to a vertical platinum wire (or idle electrode) immersed in the liquid close to the anode (or cathode) but not touching it; a balance being obtained in each case by moving the slider.

In the dilute nitric acid, with a current of ·00004 ampere, the amounts of "surface-resistance" were :—

	At 14° C.	At 95° C.
At the anode.........	49266· ohms	531· ohms
At the cathode......	29784· „	494· „

By a rise of temperature, therefore, of one of the pieces of platinum of the thermo-electric couple 81 centigrade degrees, the amount of "surface-resistance" of that piece was reduced, as a cathode or in the direction of the thermo-electric current 98·34 per cent., and in the opposite direction, or as an anode, 98·92 per cent.; and the total "surface-resistance" in the circuit was also reduced 37·05 per cent. in the direction of that current, and 61·65 per cent. in the opposite one.

The results also show that the cold platinum offered 39·55 per cent., and the hot platinum of 6·97 per cent., less amount of "surface-resistance" as a cathode than as an anode; also that the total amount of such "resistance" in the two directions in the circuit, when one of the junctions was heated to 94°C., was 64·14 per cent. greater in the direction of the thermo-electric current produced than in the opposite one.

In the dilute sulphuric acid, with a current of ·00001 ampere, the amounts of "surface resistance" were :—

	At 14° C.	At 95° C.
At the anode	63500· ohms	3848· ohms
At the cathode ...	18350·	2152· „

By a rise of temperature, therefore, of one of the pieces of platinum of the thermo-electric couple 81° C., the amount of "surface-resistance" of that piece was reduced in the direction of the thermo-electric current or as a cathode 88·27 per cent., and in the opposite direction, or as an anode, 93·94 per cent.; and the total "surface-resistance" in the circuit was also reduced 19·79 per cent. in the direction of that current, and 72·88 per cent. in the opposite one.

The results also show that the cold platinum had 71·10 per cent. and the hot platinum 44·08 per cent. less amount of "surface-resistance" as a cathode than as an anode; also that the total amount of such "resistance" in the two directions in the circuit, when one of the junctions was heated to 94° C., was 195·75 per cent. greater in the direction of the thermo-electric current than in the opposite one.

The results obtained with these two liquids show that the amount of "surface-resistance" at each junction of such thermo-electric couples varies very greatly with temperature; and that the amount of such "resistance" to the passage of a current in either direction was more largely decreased by rise of temperature with the dilute nitric than with the sulphuric acid. I had previously found with thermo-electric couples composed of metals and electrolytes, "that by rise of temperature 'transfer-resistance' was usually and considerably reduced." (*Proc.* Roy. Soc., 1885, No. 236, p. 210.)

The direction of thermo-electric current produced in each of these two cases was the same as that indicated by the relative amounts of "surface-resistance" in opposite directions at the heated junction, but the reverse of that indicated by the relative total amounts of such "resistance" in opposite directions in the entire circuit.

As in each of the two couples, the total amount of "surface-resistance" in the circuit when one of the junctions was heated, was very much greater in the direction of the thermo-electric current produced than in the opposite one, I conclude that the direction of that current was not chiefly determined by the alteration of such "resistance" by rise of temperature. The thermo-electric action, and the "surface-resistance" therefore, appear to be largely distinct phenomena; and as both liquid and metal in those couples were thermo-electro-positive substances, the direction of the current was probably caused chiefly by the thermo-electric-positive potential of the liquid, increasing more rapidly than that of the metal by rise of temperature. We may also infer that the strength of the thermo-electric current in those couples was very largely increased by the great diminution of "surface-resistance."

In a paper on "Some Relations of Heat to Voltaic and Thermo-electric Action of Metals in Electrolytes" (*Proc.* Royal Soc., 1884, No. 233, pp. 251-290), I have shown by numerous experiments that "when metals in electrolytes were heated they were more frequently rendered electro-positive than negative, in the proportion of about 2·8 to 1·0; the proportion in strong solutions was about 3·27 to 1."

Second.—With regard to voltaic couples. As heat affects largely the amount of "surface-resistance," and the strength of current, in a thermo electric couple composed of a metal and an electrolyte, we may infer that it would also, chiefly by altering that "resistance," affect the strength of current in a voltaic cell.

In order to experimentally examine this, the lower platinum plate in the thermo-electric apparatus already described was replaced by a rod of amalgamated zinc 8·0 mm. long and 2·0 mm. thick, the upper platinum plate being retained in its place. The tube was then filled with the cold mixture of one volume of sulphuric acid and 10 of water.

With the entire apparatus and liquid at 14° C., the electromotive force (determined by the above-named method) was ·704 volt., and the strength of current without additional resistance in the circuit was ·022 ampere.

With the platinum plate and upper portion only of the liquid at 95° C., and the zinc electrode and liquid around it at 14° C., the electromotive force was ·763 volt., and the strength of current 0·705 ampere.

These results show that the electromotive force was increased about 8·38 per cent., and the strength of current 220 per cent., or to 3·2 times its original amount, by raising the temperature of

Digitized by Google

the platinum negative 81 C. degrees. This increase of strength of current was about 24 per cent. greater than when the lower plate was composed of platinum. This great increase of current was, I consider, largely due to decrease of "surface-resistance" at the negative plate, and in some measure also to the increase of electromotive force attending increased thermo-electro-positive potential of the liquid; also to several other manifest but minor circumstances, such as diminished conduction-resistance of the liquid, &c.

Third.—With regard to the thermo-electric phenomena of metals. Some experiments were made to try and detect any special degree of resistance at the junctions of ordinary metallic thermo-electric couples in the following manner.

The first couple consisted of a smooth horizontal bar of bismuth, and one of antimony, soldered end to end; each bar being 2·0 cm. long, ·7 cm. wide, and ·5 cm. thick. Whilst a current of ·2 ampere was being passed from one end of the bar to the other, the ends of two thin copper wires, about 1·0 cm. apart, forming the terminals of a Thomson reflecting galvanometer of 3,040 ohms resistance, were slid very slowly at right angles to and in a horizontal direction, from one end to the other, to and fro, along the upper surface of the couple; the direction of voltaic current being occasionally reversed. Under these conditions, a small portion of the current passed through the galvanometer. There was no sudden change in the deflection of the needles at any time when the wires crossed the junction of the two bars. A similar negative result occurred when a thermo-couple formed of iron and German silver wires 1·5 mm. diameter was employed; and also when a pair composed of platinum wire and mercury was used.

Had there existed a difference of resistance equal to ·001 ohm at the junction in either case, it would probably have been detected. I conclude, therefore, that if "surface-resistance" of any kind exists at the junctions of metallic thermo-electric couples, it must be exceedingly small in amount, and that it does not sensibly affect the direction or strength of the currents produced by them.

Some attempts were made to ascertain whether the amount of "transfer-resistance" at an electrode formed of a loop of platinum wire was affected by passing a separate current of electricity through it simply as a conductor, but the results were not satisfactory.

Various of the results of experiments described in this paper agree with the conclusion that differences of "transfer-resistance" are incapable of producing a current, and are essentially unlike differences of electric potential; also, that heat decreases "transfer-resistance" whilst increasing contact-potential in metal-electrolyte thermo-electric couples.

DYNAMO TESTS.

(Concluded from page 357.)

The tables show a gradual decrease in the efficiencies, the difference between the first and last values being about one per cent.

The cause seems to be the different amounts of lead given the brushes. If we compare the first with the third test, it will be seen that, with about the same current in the field and a greater number of revolutions of the armature the E.M.F. of the latter test is about five volts less than that of the former. In the last test, with the speed still further increased and with the field current about constant, the E.M.F. is slightly less than in the third measurement.

The partial load tests were made after the constant had become steady. After the three-quarter load test, a measurement was made on full load. As it was not made under the provisions of the code, it is marked "unofficial" in the table. The half load test was repeated to check the former measurement. The difference of ·3 per cent. in the total efficiencies is probably accounted for by the slight increase of armature friction caused by running on the three-quarter load. The greatest value of the commercial efficiency is on three-quarter load, the slightly less value of the total efficiency, as compared with the full load, being more than counterbalanced by the smaller loss in the armature and field

Weston No. 6 M. Dynamo.

Diameter of armature	$8\frac{1}{32}$in.
Weight of machine	2,000
Number of commutator bars	72
Total number of turns	144
Turns per commutator segment	2
Average length of a turn	6ft. 5in.
Must brushes be adjusted?	slightly.
Diameter of bearing, pulley end	$1\frac{5}{8}$in.
Diameter of bearing, commutator end	$1\frac{3}{8}$in.
Length of bearing, pulley end	$6\frac{3}{4}$in.
Length of bearing, commutator end	5in.
Number of turns per minute	1,150
Volts for best work	120
Amperes for best work	80

Table IV., on p. 376, gives the results of the measurements.

The full load measurements probably agree as closely as the conditions of the tests. There was a good deal of sparking at the brushes, and the machine seemed overloaded.

For the partial loads, the total efficiency increased up to the three-quarter load, and there was little sparking at the commutator. On the unofficial full load test, the sparking was quite violent, and the efficiency fell about two per cent. from the three-quarter load. Comparing the unofficial full load with the tests of the day before, and applying the difference of armature friction to the former, it will be seen that the total efficiency for the unofficial test is less, the load being greater and the efficiency at this load decreasing rapidly as the load increases.

Edison No. 4 Dynamo.

Diameter of armature, $6\frac{1}{4}$in. inside, $7\frac{1}{16}$in. outside.	
Weight of machine	1,470
Number of communicator bars	50
Turns in one coil	2
Length of useful wire in a coil	48in.
Must brushes be adjusted?	Yes.
Diameter of bearing	$1\frac{1}{4}$in.
Length of bearing	$6\frac{1}{4}$in.
Turns per minute	1,600
Volts for best work	125
Amperes for best work	80

Table V., on p. 376, gives the results of the measurements.

This machine was not coupled directly to the dynamometer, the high speed required being deemed unsafe. It was run by a belt from a pulley on the transmission shaft of the dynamometer. In allowing for the loss due to the belt, it was assumed that for the full load the friction of the armature was the same as that of the No. 5 dynamo.

The full load tests agree very closely, the total efficiencies increasing slightly with the horse-power, the commercial efficiences differing very little.

The measurements on the partial loads are perhaps a little low, as it is probable that sufficient allowance was not made for the belt. The temperature was much lower than for the full load tests and the belt was probably stiffer.

Edison No. 20 Dynamo.

Diameter of armature	$9\frac{1}{16}$ inside, $10\frac{5}{8}$ outside.
Weight of machine	8,331 pounds.
Number of commutator bars	44
Turns of wire in a coil	1
Length of useful wire in a coil	59in.
Must brushes be adjusted?	Yes.
Diameter of bearing	$2\frac{5}{8}$in.
Length of bearing	$10\frac{7}{8}$in.
Number of turns per minute	1,000
Volts for best work	125
Amperes for best work	400

Table VI., on p. 376, gives the results of the measurements.

The full load tests are marked unofficial, because the preliminary run of ten hours was not on full load. The machine was started at the usual time, midnight, with about the right load, but in a few hours the power fell to about fifty horse-power, and remained about the same until noon of June 19th,

* Armature insulation gave way. † Unofficial. ‡ Average of full load measurements.

when by increasing the number of revolutions, the proper load was nearly attained. The tests were to have been repeated the next day, but unfortunately the insulation of the armature gave way, making this impossible.

The tests seem to agree quite well. It is hard to compare the first full load measurement with the others, as the conditions were different. The two full load measurements made under about the same conditions agree almost exactly.

WESTON NO. 6 W. I. DYNAMO.

Length of bearing, pulley end	6¾in.
Length of bearing, commutator end	5in.
Turns per minute	1,200
Volts for best work	130
Amperes for best work	100

Table VII. above gives the results of the measurements.

The values of the total efficiency for the different measurements of this machine differ widely. The first test gives a much smaller value than the rest, and is rejected, because, whether the difference is caused by errors in the measurements, or in the adjustment of the machine, the test evidently does not represent the normal efficiency of the dynamo.

Table VIII. above gives a summary of the tests.

In the table, the full load efficiencies of the Edison No. 20 dynamo are marked "unofficial," because the preliminary run was not in conformity with the code, not because there is any reason to mistrust the results.

Of the fifty-four measurements made, four were for obvious reasons deemed unworthy of calculation. These were two tests of the Edison No. 5 dynamo, and a couple of partial load tests of the Weston No. 7 M machine, made while the constant of the potential galvanometer was unsteady. Of the remaining fifty tests, but one is rejected—a full load measurement of the Weston 6 W. I. dynamo.

Considering the care taken in standardizing all of the instruments used in the measurements, and the very close agreement of tests made on the same dynamo, it seems probable that the results given in the above table represent very nearly the efficiencies of the machines under the conditions of the tests.

The dynamos were favoured by being coupled directly to the dynamometer, and it will be seen on looking at the tables that the loss by friction was slight.

In the measurements, the ohm was taken at 106 centimetres of mercury, so in order to reduce the values to absolute measure the potentials, and therefore the efficiencies, should be reduced by about one-fourth per cent.

DIRECT SPANISH TELEGRAPH COMPANY.—The report of this company shows that after providing for the repairs of the new Bilbao cable (£2,959), and for fixed charges, there remains a credit to profit and loss of £1,449. Of this sum it is proposed to add £1,400 to reserve, leaving £49 to be carried forward.

EFFECTS OF STRESS AND MAGNETISATION ON THE THERMO-ELECTRIC QUALITY OF IRON.*

BY PROF. J. A. EWING, B.Sc., F.R.S.E., University College, Dundee.

This paper comprises a revised version of one submitted to the Royal Society in 1881, under the title "Effects of Stress on the Thermo-electric Quality of Metals, Part I.,"† along with much new matter. It deals principally with the cyclic changes of thermo-electric quality which an iron wire undergoes when exposed to cyclic variations of stress (described in the abstract of the former paper), and with the relations of these changes of thermo-electric quality to the changes of magnetism which also occur as an effect of stress. Stress was applied by exposing the wire to longitudinal pull by means of loads.

The changes both of thermo-electric quality and of magnetism exhibit that tendency to lag behind the changes of stress to which in a previous paper ‡ the author gave the name *hysteresis*, and the effects are sufficiently similar in regard to the two qualities to suggest that the changes of thermo-electric quality occur as secondary effects of changes of magnetism.

To examine whether this is so, simultaneous measurements of the magnetic and thermo-electric effects of stress in an iron wire were made, and also independent observations of the thermo-electric effects of magnetisation, without change of stress.

A comparison of these made it clear that stress causes change in the thermo-electric quality of iron directly, and not as a secondary effect of magnetisation. If the wire be completely demagnetised to begin with, and kept clear of all magnetisation during the application and removal of stress, the presence of hysteresis is not less marked than before. Experiments are given to show how the thermo-electric effects of stress are modified by the existence of more or less magnetisation of the wire; and conversely, how the thermo-electric effects of magnetism are modified by the existence of more or less constant stress. The influence of vibration in destroying the effects of hysteresis is investigated, and also the result of exposing the wire to the process of demagnetising by repeated rapid reversals of a continuously diminishing magnetising force, and it is shown that this process acts in the same way as vibration in destroying the effects of hysteresis. Residual effects of hysteresis are studied, as, for example, the difference which presents itself when a wire is magnetised after having been loaded strongly and then unloaded down to a certain constant state of stress, and, on the other hand, when the same state of stress has been produced by simply increasing the load; and it is shown that these residual effects are wiped out by vibration or by demagnetising by reversals.

With regard to the effects of stress on thermo-electric quality, it is clearly shown that if a somewhat soft wire be more and more strongly magnetised these effects become more and more similar to those which are found when the wire is hard-drawn, but not magnetised. A few experiments were made with wires of silver, copper, lead, magnesium, and German silver, but in none of these was hysteresis of thermo-electric quality with regard to load discovered.

Special attention is directed to a peculiar feature in the curves by means of which the experimental results are exhibited. In curves showing the relation of thermo-electric electromotive force to load, it is shown that any reversal from loading to unloading, or *vice versâ*, causes an inflection in the curve, the first effect of the new process being to continue the kind of change of thermo-electric quality that was going on before.

That this is not caused by any mechanical disturbance which the loading or unloading produces is shown by the fact that it occurs in an equally marked way after the molecules have been brought to a condition of stable equilibrium by vibrating the wire before beginning to load or unload. It is suggested that the effects of hysteresis, described in the paper, have a possible relation to the properties which Prof. Osborne Reynolds has recently shown to be possessed by granular media.

The experiments described in the paper are closely connected with those which were communicated to the society in January, 1885, under the title "Experimental Researches in Magnetism," and are now being published in the *Philosophical Transactions.* They were conducted in the Physical Laboratory of the University of Tokio in 1881-3, partly with the help of one of the author's Japanese students, Mr. S. Sakai. The results are given graphically, and are for the most part reduced to absolute measure.

* Abstract of a Paper read before the Royal Society on the 11th March, 1886.

ELECTRICITY IN THE FUTURE.

Mr. J. Johnston, in a paper recently read in America upon motors, says:—

The future electric station will be erected to utilise power in hundreds of ways not now thought of. Central stations should be made large enough to combine all the present methods of using electricity, with full allowances for future discoveries, for I believe electricity is in its infancy. By this strange and novel agency power will be used to do its share toward the support and advacement of the human race. We may yet know, in our time, what electricity is, for to-day we only know it is a power that shows itself by its manifestations. A professor in a college asked a student one day what electricity was. The student hesitated and tried to think of the correct answer, but in vain; it was of no use. He could not recall it, but in self-defence said, "I did know, but have forgotten." The professor replied, "This is terrible. The only man who ever knew what electricity was has forgotten the answer." Electric light and power stations will be erected in the future as large as our present cotton mills. The engines will be used in the daytime to run lines of shafting to furnish power for manufacturing purposes over the station. Power motors will transmit electricity all over our cities to run small machinery. Both arc and incandescent lights will be used. Perhaps storage may yet be a success. Electricity will be used to drive machiney, to produce ventilation, for heating purposes.

The exhaust steam will also be used for heating neighbouring buildings in cold weather. There is no need to expatiate upon the advantages to be gained from an economical method of transmitting power, the costly and persistent attempts of inventors and capitalists to get better methods are enough to prove their desirability. Many systems have been tried and found wanting. In electricity, thanks to the living inventors, we have a force into which power can be transformed, as by the wave of the magician's wand, a force which flows to any distance with the rapidity of lightning and the stillness of a ray of sunlight, and then at bidding resumes its original shape quicker than thought can follow it.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting of this Society on Thursday evening, 11th inst., held in the Institution of Civil Engineers, Great George-street, Westminster, two papers by Profs. AYRTON and PERRY were presented, the one on "Economy in Electrical Conductors," which was read by Prof. AYRTON, and which we have printed at length elsewhere; the other, read by Prof. PERRY, on "Some Problems in Telpherage." Owing to the lateness of the hour the last-named paper was not discussed; and the third paper which had been announced for that evening, by the same authors, "Note on Magnetic Resistance," was postponed. But the reading of the first of these papers gave rise to a discussion, or rather altercation, which, although of no particular interest, was evidently enjoyed by the audience as a relief to the wearisomness of listening to a long, dry mathematical discourse. Without

Digitized by Google

denying that the calculations embodied in the paper would prove suggestive and useful in certain conditions, the general opinion appeared to be that those problems which were really a difficulty for practical electrical engineering just now had been left quite as obscure as ever, perhaps more so, by the elaborate equations and tables travelled over that evening. Prof. FORBES, Mr. CROMPTON, and Dr. FLEMING spoke more or less in this sense; and the former protested also that the authors had wholly misrepresented or misunderstood Sir W. Thomson's statement with regard to the proper sectional area for a copper conductor used in transmitting electric energy; and that a large portion of the paper purported to be a correction of an error which Sir W. Thomson never committed. After Prof. PERRY's reading of the paper on "Telpherage," the usual vote of thanks concluded the proceedings.

ELECTRIC LOCOMOTION.

A lecture on this subject was given by Mr. A. Reckenzaun on the 10th inst., at a meeting of the East of London Association of Marine Engineers and Foremen, at the Poplar Town Hall. The lecturer prefaced his lecture by explaining the general principle involved in the production and transmission of electric currents, and after alluding to several instances of the successful use of electricity to railways, &c., in this country and abroad, he proceeded to describe more in detail the various methods resorted to by different inventors for transmitting the energy when once it has been generated. Attention was also specially directed to the mechanical details of construction of the complete propelling apparatus. Incidentally appropriating his remarks to his audience, Mr. Reckenzaun took occasion to point a moral by touching upon the advisability—one may say the *necessity*—to all mechanical engineers of obtaining a thorough knowledge of electrical science, "for electrical engineering is," he said, "rapidly becoming an important branch of *mechanical* engineering, and it is *through* the judicious combination of the experiences gained from each that electricity has made, and will continue to make, such rapid advances in practical utility in such many and various directions. Mechanical engineers are too apt to look upon electric locomotion as nothing better than an expensive amusement, and to exclaim against the process of first converting steam power into electric energy, then transforming this energy into mechanical power, basing their objection upon the loss thereby of a considerable percentage of the original available force in the course of this double, sometimes treble, conversion."

The lecturer went to the very root of this matter. Beginning with the efficiency of the dynamo, and following up the possible loss through resistances in conductors and motors, friction in motors, and gearing of, for instance, an electric tramcar, he proceeded to show most conclusively that in many instances it is more economical to convert steam into electricity, and use the latter for propulsion, than to apply steam direct upon a locomotive. A locomotive must, for obvious reasons, be *at least* as heavy as the vehicle it draws. By placing the electric motor under the car to be propelled, and which itself carries the passengers, we obtain two great advantages. We got rid of the great weight of the extra vehicle, weighing from six to ten tons, and which requires two-thirds of its power to move itself, while, again, we make use of the dead weight of the passengers and the motive-power mechanism to produce the necessary adhesion to the rails. Thus in a car whose motor receives its energy through conductors the motive power apparatus need not weigh more than half a ton, or, taking the system of storage batteries, with its extra ton of cells, we have a great gain over a steam locomotive or any other of similar weight. Considering that the tractive force must be proportionate to the load to be carried, it must be evident that, with so great a saving in dead weight, we can readily afford to lose a large portion of the energy in transmission and conversion. No one would be so foolish as to put a separate locomotive upon a tram line if he could place the motor on the car. Exceptional cases present themselves where a system of haulage has its advantages, such as in "telpherage"—the transport of goods along overhead rods carried upon posts—but even there the locomotive must possess special appliances for providing a sufficient "grip" upon the rods. Another instance was that of underground haulage in mines, where a number of small trucks must be moved, yet where separate motors to each truck would be highly inconvenient. It was, however, a strong point in favour of electric tramcars that the motor could be made to form part of the passenger-carrying vehicle.

The lecturer's concluding remarks had reference to the construction of electric boats.

The lecture was listened to with marked attention, and a hearty vote of thanks was moved by the president of the association, Mr. George Williamson, to Mr. Reckenzaun for his interesting and instructive address.

COMPANIES' MEETINGS & REPORTS.

The Telephone Company of Egypt (Limited).

The third ordinary annual general meeting of the shareholders of this Company was held on the 16th inst., at the offices, 14, Austin Friars, under the presidency of Lieut.-General A. Fraser, C.B., R.E.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting and the minutes of the last meeting. The report of the Directors, an abstract of which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN then moved the adoption of the report and accounts, and the declaration of the dividend recommended, at the rate of 5 per cent. per annum (to be applied, as stated in the report, as follows:—2 per cent. in final payment of the cumulative preferential dividend of 7½ per cent. for 1883, and 3 per cent. in part payment of the cumulative preferential dividend of 7½ per cent. for 1884).

Mr. G. B. FROST seconded the resolution, which was carried unanimously.

On the motion of Mr. FROST, seconded by Mr. THOS. LLOYD, Lieut.-General Fraser was re-elected to his seat at the Board, Mr. Frost expressing his conviction that the very satisfactory state of the Company was a great deal due to the successful management of the Chairman.

The CHAIRMAN, in acknowledging his reappointment, stated that his earnest desire was to carry on the working of the Company successfully. Hitherto he thought they had been very successful, but he must say that that was not due so much to the direction here as to their staff in Egypt. Mr. Evans had throughout carried on the business there very successfully, and was a man to be trusted. They did trust Mr. Evans, and on no occasion had he ever found that that gentleman had given them reason to suppose that their trust might not be continued in him. He would like to be able to let Mr. Evans know that the shareholders generally approved of the work which he had done, and of the work of the staff under him, which in the opinion of the Directors was entirely satisfactory.

Mr. HENTSCH then moved the re-election of the auditors of the Company, Messrs. Price, Waterhouse, and Co., at the remuneration of fifteen guineas.

Mr. FROST seconded the resolution, which was carried unanimously.

On the motion of Mr. FROST, seconded by Mr. HENRY GREWING, a vote of thanks was passed to the Chairman, and the proceedings then terminated.

National Company for the Distribution of Electricity by Secondary Generators (Limited).

The third ordinary general meeting of the shareholders of this company was held at the registered offices of the Company, 18, Warwick-street, Regent-street, on the 18th inst., under the presidency of Mr. William D'Oyly.

The SECRETARY (Mr. J. E. Pickering) read the notice convening the meeting, and the report of the directors, which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN formally moved the adoption of the report and accounts.

Mr. J. DIXON GIBBS: I have much pleasure in seconding the motion, but I think, in doing so, that very few remarks are necessary to supplement the sense of the report itself. The business generally is improving, as you see, and in many directions we have good promise for the future. The amount referred to as having been received from the Banque d'Escompte for the current year—up to the 1st of February of this year—is only £1,087. That is the balance of 40,000fr., or £1,300, due for the year ended the 1st of February, 1886; but for the year ended the 1st of February, 1887, there will be a *minimum* of 100,000fr., or £4,000. That is the annual *minimum* for this year. With regard to the work done, the only addition that is worth noticing since the report was printed is the opening of a further portion of the Tours installation, which M. Gaulard has just returned from effecting most successfully. The apparatus is ready, and is going out for the Italian installations, which may be expected to be opened in the course of the next month. I think that that is all I need say in further explanation of the report, and I beg to second its adoption.

Mr. KENNETH MACKENZIE referred to the item in the balance-sheet of plant and machinery, £4,444, and asked how it was made up, as it seemed to him a very large amount.

The CHAIRMAN stated that it included three dynamos, two of which had been sold; the generators which were used in the installation on the Metropolitan Railway, the workshops, tools, &c.

Mr. MACKENZIE inquired how the valuation had been made, and whether it was upon the present or the cost value of the plant.

The CHAIRMAN stated that the cost value had been reduced and taken off.

Mr. GIBBS pointed out that since the date of the report two of the principal items embraced in the total had been sold—two large dynamos—and that would reduce the amount. The items had been taken at a very low value, and the amount shown included the plant they had at Turin.

Mr. GLOVER: You have written off £360 in the profit and loss account?

The CHAIRMAN: Yes.

Mr. MACKENZIE: It may be taken, then, that this is a fair amount of what the value is?

Mr. CAMPBELL: Not what it is, but what it was on the 31st of December.

Mr. MACKENZIE stated that the preliminary expenses were shown at £486, of which £54 had been written off. He wished to know whether the amount was in connection with the original formation of the Company.

The CHAIRMAN replied in the affirmative.

Mr. MACKENZIE asked why only £54 had been written off.

The CHAIRMAN: Because we cannot write it all off in one year. It is a necessary expenditure in the first instance. If we wrote off all these

Digitized by Google

things at once we could not expect to show any profit. We have written off some this year, and we hope to write off a good deal next year.

Mr. GLOVER stated that more than 10 per cent. had been written off, and it seemed to him that if that amount were written off every year it would meet the case.

Mr. CAMPBELL pointed out that the universal practice was to write off so much a year.

The CHAIRMAN then put the resolution, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. GUSTAV DUFRESNE, the following resolution was carried unanimously:—"That a dividend be paid on the preferred shares at the rate of 10 per cent. per annum from the respective dates of allotment to the 31st December, 1884, payable forthwith."

Mr. GIBBS proposed the re-election of the retiring Directors, Mr. D'Oyly and Sir James D. Mackenzie, Bart.

M. GAULARD seconded the motion, which was carried unanimously.

The CHAIRMAN having acknowledged his re-election, proposed a resolution confirming the appointment as a director of Mr. Gustav Dufresne to fill the vacancy caused by the death of Mr. Le Fez. The Chairman stated that the Directors had the power, under the Articles of Association, to make the interim appointment, but such an appointment had to be confirmed at the following general meeting. He, therefore, proposed the confirmation of the appointment of Mr. Dufresne, whom they had found of great assistance at the Board from his commercial knowledge and other qualifications.

Sir J. MACKENZIE, in seconding the motion, said he thought the Company were to be congratulated on the accession to the directorate of so able a coadjutor as Mr. Dufresne. They had been very much in want of the commercial element to which the Chairman had referred, and in Mr. Dufresne they had certainly got a very able and thorough business man to help them. Moreover, bearing in mind the general character of the Company, they were very much in want of a linguist, and in Mr. Dufresne they had the services also of an accomplished linguist.

The CHAIRMAN put the resolution, and it was carried unanimously.

On the motion of Mr. NURSER, seconded by Mr. LUDEZ, the auditor (Mr. J. H. Thornton) was re-elected.

Mr. CAMPBELL then proposed a vote of thanks to the Chairman and Directors—to the Directors for the able manner in which they had carried on the business up to the present time, having brought the ship into clear water, and given the shareholders a dividend, and to Mr. D'Oyly for presiding over them that day.

Mr. GLOVER seconded the motion, and said he thought the shareholders ought to be very much congratulated on the successful way in which the Directors had piloted the ship, especially in view of the depressed condition of electric lighting generally. If the electric lighting industry had been brighter, the Company would have had better returns than they had made. As it was, however, he thought the progress which had been made was very satisfactory, indeed.

The CHAIRMAN acknowledged the vote, and expressed regret that the attendance of shareholders had not been larger.

Mr. GLOVER said he did not think shareholders cared to trouble to attend a satisfactory meeting.

Mr. GIBBS said he had no doubt that that was the explanation of the thin attendance. In answer to Mr. K. MACKENZIE he added that the whole of the details of the Tours installation had been given to the Société d'Electriciens, and would be published *in extenso* in the next *Journal* of that society.

The CHAIRMAN stated that the first part of that installation was opened about two months ago, and the second section had just been opened.

Mr. GIBBS added that there were two circuits of 2,000 metres each.

The proceedings then terminated.

Direct Spanish Telegraph Company (Limited).

Report of the Directors for the half-year ended 31st December, 1885, to be presented at the general meeting of shareholders on Tuesday, the 23rd inst., at half-past two o'clock:—

The accounts show, after paying for the repairs of the new Bilbao cable (£2,959. 13s. 7d.) and providing for debenture interest, a balance to the credit of profit and loss of £1,449. 5s. 2d. The traffic receipts show an increase of £287. 14s. 9d. as compared with the corresponding half-year of 1884, and an increase of £1,111. 12s. over those for the last half-year. The repairs of the new Bilbao cable, the interruption of which was mentioned in the last report of the Board, were promptly and economically effected. The cause of this break, which occurred in very deep water, cannot be ascertained. The entire cost of these repairs, it will be noticed, has been paid out of the revenue for the half-year. The new Bilbao cable has, since the repairs, worked perfectly. The Marseilles-Barcelona cable has remained in excellent working order throughout the half-year. The Directors are arranging to have the original Bilbao cable examined in the course of this summer, with a view to ascertain its condition. The Directors propose to put £1,400 to the reserve fund, which will then amount to £9,800, and to carry £49. 5s. 2d. to the next account. Sir James Anderson and Mr. John Denison Pender are the Directors retiring by rotation, and, being eligible, offer themselves for re-election. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

Swan United Electric Light Company (Limited).

Report of the Directors to be presented at the adjourned ordinary general meeting of the Company, to be held at the Cannon-street Hotel, on Tuesday, the 23rd inst., at one o'clock:—

The Directors remark that, as a copy of the last report of the Edison and Swan Company was sent to every shareholder, it is not necessary to allude further to the English business. The shareholders are aware that the Company is engaged in litigation with the German Edison Company and with the Continental Edison Company which control the Edison patents in Austro-Hungary, Belgium, France, Russia, Spain, &c. Believing it to be for the interest of all concerned that this litigation should be brought to an end, the Directors have spared no effort to arrive at some fair and equitable settlement with the Edison companies on the Continent. Negotiations have been carried on with this end in view; those with the Continental Edison Company are still in progress, but it seems as if in Germany the suits must be fought out. It will be seen on reference to the last balance-sheet that the loss which had accrued up to 30th June, 1884, amounted to £2,327. 7s. 9d., to which must be added that on closing the Paris Factory in 1884, £1,128. 14s. 8d., and by the fire at Lille, £1,094. 2s. 11d. The loss during the year ending 30th June, 1885, as shown by the profit and loss account, amounts to £6,258. 9s. 7d., which, added to previous loss, brings the total up to 30th June, 1885, to £10,808. 14s. 11d. The Lille and Cologne Factories were not in working order until the spring of 1885. During the end of 1884 and the early part of 1885 the Company had to purchase lamps to supply their customers. In spite of legal proceedings and most active rivalry the business of the Company improved in the quarter ending 30th September, and shows a favourable balance of £3,206. 0s. 5d., thus reducing the amount standing at debit of profit and loss at that date to £7,602. 14s. 6d. Heretofore the accounts have been made up to 30th June in each year; the Directors propose that the financial year shall in future end on 30th September, and for that reason they now present the accounts to the shareholders for fifteen months. The question of the distribution to the shareholders of the shares allocated to this Company in the Edison and Swan Company has received the most careful consideration of the Directors, but they find that such distribution cannot take place pending the legal difficulties before referred to. Messrs. J. W. Swan and C. H. Stearn, directors, retire by rotation, but, being eligible, offer themselves for re-election. The auditors, Messrs. Quilter, Ball, and Co., also offer themselves for re-election.

BUSINESS NOTICES.—Messrs. Eck, Callow and Co. notify that Mr. D. J. Callow retired from the firm as from the 3rd day of February last, and has no further connection with or interest therein. Mr. Cecil B. Callow is general manager.—Messrs. Frederick Young and Co. notify that Mr. D. J. Callow and Mr. M. A. Callow retired from the above firm as from the 3rd day of February last, and have no further connection with or interest therein. Mr. Cecil B. Callow is general manager.

NOTES.

MONTEVIDEAN AND BRAZILLIAN COMPANY.—The ordinary meeting of this company is postponed from March 25th to April 7th.

THE CABLE FLEET.—We hear that the Eastern Extension Company's new ship, "The Recorder," reached Singapore on Tuesday last.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 19th inst. amounted to £3,134.

METROPOLITAN TRAMWAYS. — The North Metropolitan Tramways Company is applying to Parliament for powers to use electricity as a power for moving carriages on their lines in West Ham, East Ham, and Leyton.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 19th inst. were £2,549, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

OBITUARY NOTICE.—We regret to announce the death on Saturday, the 13th inst., of Mr. Robinson Kendal (Chairman of the West Coast of America Telegraph, and South of England Telephone Companies), at the age of forty-eight years. The cause of death was heart disease.

BOOK RECEIVED.—"Electricity Treated Experimentally, for the Use of Schools and Students," by Linnæus Cumming, M.A. This work is published by Rivingtons, Waterloo-place, London, and contains the substance of experimental lectures delivered to some of the senior boys in Rugby School.

ANOTHER ELECTRIC LIGHT BILL.—Lord Bury has introduced a second Electric Lighting Act Amendment Bill into the House of Lords. We have been unable as yet to obtain a copy of the Bill from the Queen's printers, who say it will not be ready for a few days. Hence we reserve any remarks we may have to make till the text of the Bill is before us.

SUEZ CANAL.—According to a telegram from Lloyd's agent at Ismailia, the "Carthage," lighted by electricity, left Port Said at eight o'clock on Monday night, passing through the Canal during the night, and arriving at Ismailia at 5 a.m. on Tuesday. We believe this is one of the first instances of steaming through the Canal during the night, and that it can only be done by the aid of the electric light.

THE BERLIN NATIONAL EXHIBITION IN 1888.—We learn from Berlin that the general feeling of manufacturers, engineers, and electricians, which for some time was rather adverse to the idea of another exhibition with all its attendant expenses and loss of time, is gradually giving place to a more enterprising spirit, and it is probable that the German manufacturers of dynamos, motors, and lamps will very largely exhibit.

THE INSTITUT ELECTRO-TECHNIQUE MONTEFIORE.—This University in Liége was founded, about two years ago, by M. Montefiore-Levi. It is intended to educate electrical engineers in the same manner as the Continental polytechnic schools are intended for the education of mechanical and civil engineers. The average number of lessons given on theoretical electricity is 70 per term, and that of technical electricity is 140 per term.

GREAT NORTHERN TELEGRAPH COMPANY.—The ordinary meeting of this company will be held in Copenhagen on April 21st. The following business will be submitted:—A report of the business for the past year, and of the condition of the cables and other property; production of the accounts and balance-sheet, resolution to be passed of the amount of dividend to be paid for the past year, and discharge given to the directors for the same period; &c., &c.

A PHOTOGRAPHIC INDICATOR DIAGRAM OF THE WORKING OF A PRIMARY CELL.—Messrs. Trowbridge and Hayes pass the current through a mirror galvanometer and photograph the image of a lamp on a revolving drum covered with sensitised paper. A curve is obtained which shows the variation of current strength as a function of time, and gives a clear idea of the falling off in current strength due to polarisation and other causes when the resistance in circuit is kept constant.

A STANDARD OFFICE FOR ELECTRICAL UNITS IN GERMANY. At the last meeting of the Berlin Society of Electricians, Prof. Rühlman proposed that the German Government be petitioned to legally define the electrical units now in use, and to establish an office for electric measurements where a legal standard of resistance should be kept, and used as a basis for standardising resistances supplied to the public. The proposal was seconded by Prof. Foerster and Dr. W. Siemens, and unanimously adopted.

THE POWER OF THE HUMAN EYE TO DETECT MINUTE TRACES OF COLOUR. — Interesting experiments have been made by E. L. Nichols on the quantity of colouring matter which must be mixed with a perfectly white powder (carbonate of magnesia) before the human eye can detect it. From these experiments it appears that red and yellow are most easily detected, 16 and 17 parts respectively being sufficient for detection when mixed with a hundred million parts of white powder.

TRANSMISSION OF DIFFUSED LIGHTS ACROSS A GAUGE SCREEN.—Langley observes in *Silliman's Journal* that the ratio of the open surface to the total surface of a screen formed of wire gauge corresponds fairly well with the percentage of diffused light which the screen allows to pass. This is also the case when several screens are placed close together, the intensity of the light decreasing in geometrical progression with the number of screens; but for concentrated light the reduction is much greater.

ARC LIGHTING IN BELGIUM.—There seems to be a wide field for arc lighting in Belgium if we may judge from the number of foreign arc lamps which were exhibited during the recent electrical exhibition at Antwerp. It is also interesting to note that out of the ten exhibitors showing a total of 250 lamps, only two were by Belgian firms, with only 62 lamps. The following is a lists of the lamps shown:—Brush 45, Zipernowski 20, Gramme 13, De Puydt 32, Jaspar 6, Pieper 24, Patterson 52, Spieker 32, Crompton 4, Piette and Krizik 22.

PRIMARY BATTERY FOR LIGHTING PRIVATE CARRIAGES.—Herr Vohwinkel, in Vienna, manufactures a primary battery which is intended to be placed under the driver's seat, and which gives a current of 18 ampere hours at 36 volts pressure. The cells are enclosed in a wooden box, 23in. by 8in. by 9in., and a switch is fitted to the driver's seat, by which the current can be interrupted. It is stated that there is hardly any local action when the switch is off. The cost of keeping alight three 7-candle lamps for nine hours (after which time the battery has to be recharged) is stated to be 2s.

TELEPHONES AND FIRES.—Another instance of the value of the telephone in cases of fire is to be noted in connection with the recent alarming fire at Lemberg. The fire originated at five o'clock in the morning, and immediately on its discovery

Digitized by Google

the alarm was telephoned to the fire brigade, who arrived on the spot in time to save the building. The advantages of the telephone system were so apparent that the mayor of the town directed the superintendent of the exchange to call upon him with the view to its extension, which will increase by so much the business for the Telephone Company of Austria.

FIRE AT THE CAVALRY BARRACKS, BRIGHTON.—On Sunday night a fire broke out in the store room of the Cavalry Barracks, and, owing to a short supply of water, it rapidly spread, and got beyond the control of the regimental brigade. A trooper was therefore despatched to the Volunteer Fire Brigade Station, whence the alarm was sent by telephone to the other stations. The Hove Volunteer Brigade by this means was enabled to arrive at the fire within half an hour of the alarm being given, during which time the men were got together, horses procured, and a distance of about three miles covered.

SHIP LIGHTING.—Some time ago the London and Edinburgh Shipping Company issued specifications for the lighting by electricity of their steamer "Malvina," and the estimate submitted by H. Bennett and Co., of 45, Bothwell-street, Glasgow, was accepted. The installation consists of an Andrews patent dynamo, 68 twenty candle-power lamps, and one of Tangye's Soho engines. The lighting has been divided into four circuits, controlling respectively the saloon, second cabin, engine room, and holds. The steamer has been fitted throughout on the single wire system, and the result has proved entirely satisfactory.

ELECTRICITY IN MINES.—In a paper recently read by Mr. C. Roberts, at the Junior Engineer and Scientific Society, at Glasgow, the difficulties of lighting mines safely and effectually were dealt with, and Mr. Swan's self-contained miner's safety lamp was fully described. Mr. Roberts also entered into the question of blasting by the aid of electricity generated by a small hand dynamo, and described the application of electricity to signalling in mines. The paper concluded with a short review on the present state of the electrical transmission of power, and its application for working fans, pumps, and other machinery.

CALORIMETRIC DETERMINATION OF THE TRUE OHM.—We learn from a recent number of *Silliman's Journal* that Mr. Fletcher has attempted to calculate the value of the true ohm in B.A. units by measuring the heat developed in a wire by the passage of a known current during a given time. According to Joule's law the heat $Q = \frac{C^2Rt}{W}$, where C represents the current, R the resistance, t the time, and W the mechanical equivalent of a heat unit. He finds that W = 42,068,000 B.A. units, and that the B.A. ohm is ·9904 of a true ohm. This figure is considerably higher than the mean of the latest determinations in England and on the Continent, which is ·9887.

THE UNITED STATES.—The telegraphs of the United States are almost entirely in the hands of the Western Union Telegraph Company, which had in 1884 145,037 miles of line, 450,571 miles of wire, and 13,761 offices; the number of messages sent in 1884 was 42,076,226, the receipts 19,632,940 dollars, expenses 13,022,504 dollars, and profits 6,610,436 dollars. Including minor companies, there were altogether 164,000 miles of telegraph line open for public use in 1884. In 1884 there were 96,000 miles of telephone wire belonging to one company, with 307,010 telephones, and 906 telephone exchanges. Altogether it is estimated that in the beginning of 1884 there were 120,000 miles of wire for telephone use.

REGISTERED TELEGRAPHIC ADDRESSES.—In the House of Commons on Tuesday last Mr. H. Fowler said, in answer to a question of Mr. D. Smith:—"There are, the Postmaster-General tells me, several objections to the official publication of a list of registered telegraphic addresses, the chief among them being that inconvenience to the public would arise from messages being addressed to names which, although appearing in a periodical list, had ceased to be registered. Numerous alterations, I should explain, take place in the register every day, some names being altered, and others withdrawn. I may add that certain persons strongly object to the publication of their registered addresses." On Thursday night Mr. Labouchere was to ask a question in the House as to the expediency of reducing the fee for registered telegraphic addresses in provincial towns to one half.

THE HEFNER-ALTENECK STANDARD FOR LIGHT.—Dr. Bunte has recently experimented with Hefner-Alteneck's standard lamp, burning amylacetate by means of a solid wick 8·3 millimetres in diameter, and has added certain improvements by which the height of the flame can be more accurately adjusted. He has also observed that the purity or otherwise of the atmosphere in which the lamp burns has a very marked influence on the amount of light given out. Photometric rooms are generally so closed up from all sides that ventilation is imperfect. Special attention should be paid to this point, as the lamp will only give one standard candle if burning in a quiescent and pure atmosphere. The wick tube must be eight millimetres wide and the total height of the flame must be forty millimetres, and the lamp should be left to burn at least for ten minutes before a measurement is taken.

EDISON AGAIN.—The *Daily News*, *Nottingham Daily Express*, and other papers, have commenced another "Edisonian" boom. This time Edison has worked out the problem of communicating with a train in motion, and, of course, is said to do this by some wonderful discovery of his into the unknown regions. When the whole thing is calmly discussed by the aid of diagrams the wonderful is not to be found, and only the ordinary apparatus appears. Who but the veriest tyro in electrical knowledge can subscribe to such sentences as—"The current generated on the train can be made to leap to the ordinary telegraph wires, thus obviating the necessity for having any special wire laid near the rails;" and, "The electrical message which Edison could shoot 50 feet through the air he now finds can be projected 580 feet without a wire or other conductor?" This is amusing, but it is not science.

LIGHTHOUSE ILLUMINATION.—Mr. Wigham, writing to *The Times* on March 16th, among other things, refers to the electric light in the following terms:—"Mr. Edwards repeats the conclusions of the Trinity House, and, making no mention of gas, states 'that for ordinary necessities of lighthouse illumination mineral oil is the most suitable and economical illuminant, and that for salient headlands, important landfalls, and places where a very powerful light is required electricity offers the greatest advantages.' So far from this being the case, the investigations of scientific men unconnected with the Board of Trade or the Trinity House, the two institutions being practically one, will prove that for great headlands the electric light is the worst that could be used for effect, and the greatest in expense; that for ordinary lights of sufficient power to show to the horizon in clear weather mineral oil is the cheapest; but that for great headlands and other important stations where the clear weather light requires to be augmented for foggy weather, the cheapest and by far the most powerful light is that of gas."

Digitized by Google

THEATRE ROYAL, MANCHESTER.—This installation was made in December, 1882, from which time it has worked without the slightest hitch. In January of last year the Manchester Edison Company were requested to enlarge the installation, and so put incandescent lamps in the footlights, in order to do which it was necessary to remove the gas fittings; the confidence of the lessee had not been sufficiently strong to allow this at the outset. The lamps, which are of the Edison type, have been running about 6,000 hours; there are still many of the original ones in use, and none of the renewals have given out yet. The dynamos are four Edison 250 light machines which are worked at varying loads as scenic effects may require. During the whole time the commutators have not worn more than $\frac{1}{32}$in., and the wear of brushes has only been $\frac{7}{8}$in. each. In November, 1884, the installation was again extended in order to light the Comedy Theatre, which has been done with equal success, and a few months ago a large set of Elwell-Parker accumulators was added for the lighting of a warehouse and a concert hall in the vicinity from the theatre plant.

THE LIGHTING OF THREE RAILWAY STATIONS AT ANTWERP.—Some time ago tenders were invited for the lighting of three railway stations at Antwerp by arc lamps, and now the *Chronique des Travaux Publiques* publishes the result. The distribution of the lights was left to the parties tendering, the only condition being that no part of the floor space should have less light than $\frac{1}{50}$th carcel, equal to about 0·15 English candles. It is not stated how this illumination was to be measured. Only two electrical companies tendered—the Société Electrique in Brussels with 29 Brush lamps, having a total intensity of 33,500 candles, and the Thomson-Houston Company, with 43 lamps, having a total intensity of 25,800 candles. The cost of the plant was to be £4,600 and £5,200 respectively, and the price to be paid for running the installation £1,900 and £1,940 per annum respectively. The Antwerp Société Continental (Gas Company) offered to instal 146 gas lights, giving a total of 14,000 candles. The cost of gas pipes, and lanterns, and burners was to be £2,400, and the yearly expenditure for gas, £1,900. Therefore, with the same yearly working expenses electricity will give twice the amount of light as compared with gas.

DOMESTIC LIGHTING BY PRIMARY AND SECONDARY BATTERIES COMBINED.—M. Hospitalier, in *L'Electricien* of the 20th inst., describes his own private installation, which is so small that it would not pay to use a steam-engine or gas-engine in the usual way. The installation consists of six lamps, varying in candle-power from three to twelve, but all requiring a pressure of 10 to 11 volts. The current required by the three-candle lamps is 1·2 ampere, and that required by the twelve candle lamps is 3 amperes. There are six secondary cells connected in series, and wires lead from the five connections, and from the two terminals of the battery to a board, where they are joined to seven contact studs. The poles of the primary battery are joined in a similar way, with two switches placed on the same board, and by setting the switches so as to establish connection with any two particular contact studs, the secondary cells comprised between these points are charged. As a rule, three out of the six cells are charged at a time, the position of the switches being changed every morning and every evening. The primary battery consists of bichromate cells of one litre capacity each.

PATENT OFFICE PRACTICE IN THE UNITED STATES.—Those of our readers who have taken out patents in the United States will probably all agree that the way is beset with difficulties. The invention may be absolutely new, useful, and a proper subject for a patent, yet if the would-be patentee is not a citizen of the United States some difficulty will surely crop up. With their own countrymen the American examiners seem to be by far more easy going. Thus we find in the Official Gazette of the United States Patent Office for March 9th, 1886, a patent which closely resembles the original English patent of Varley for compound winding of dynamos. The number of the patent is 337,778, and the only point of dissimilarity with the modern compound machine is in the name. Instead of calling his invention a method for making dynamos self-regulating, the inventor calls it a regulator for dynamo-electric machines. One of the two horseshoe magnets constituting the field is wound with shunt wire, the other with main wire. The latter is considerably smaller than the former, and is called a detractor. It would from this appear that a new name for a part of the machine, and a misleading title for the whole, are sufficient to make a bad patent pass safely under the critical eye of the learned examiners in Washington.

THE LATE RAILWAY ACCIDENT ON THE RIVIERA. — Our contemporary *Electricité* points out that if means of communicating from the station with railway trains in motion had been available, this disastrous accident could have been prevented as soon as the station master had discovered his error. The immense importance of Gilliland's system of telegraphing to and from moving trains naturally suggests itself to the reader. But before this invention is perfected and actually introduced on every railway many years may elapse, and meanwhile station masters will have to rely on the old and time-honoured staff system. It seems incredible that an accident of the kind which has just taken place on the Riviera should happen at all. There is only one staff for each section of a single line, and no driver is permitted to start (notwithstanding any orders from the station master) unless he is in actual possession of the staff. Our French contemporary enjoins electricians and financiers to exert themselves in devising some electrical inventions by which similar railway disasters should be rendered absolutely impossible. It seems that *Electricité* does not know that already two years ago Mr. Willoughby Smith brought before the Society of Telegraph-Engineers and Electricians a suggestion to establish electrical communication with moving railway trains by means of inductive influence between two coils.

TELEPHONE LITIGATION.—As a good deal of interest is taken in the electrical, as well as in the legal, world on this subject, it may interest our readers to hear that there appears to have been some foundation for the rumours that the United Telephone Company (Limited) had taken active steps to stop the sale of valve telephones by the New Telephone Company (Limited). On Saturday last the case of the United Telephone Company *v.* Fleming, an action for infringement, came before Mr. Justice Chitty in court. Mr. Fleming had filed affidavits stating that, though he once had bought two Butler transmitters, the only transmitters he had ever used or sold were numerous valve telephones, purchased by him from the New Telephone Company. As that company had indemnified him against all claims for infringement, he claimed that it should defend the action brought by the United Company. This the New Telephone Company stated by their counsel they were perfectly prepared to do. The United Company, however, refused the challenge, and their counsel then stated that they were not suing Mr. Fleming in respect of the valve telephones, but in respect only of the Butler transmitters, which, according to the statement, he had never sold. Mr. Justice

Digitized by Google

Chitty, on learning that the United Telephone Company declined to include in this action the valve telephone, directed the pleadings of the United Telephone Company to be altered so as to make it clear that they did not attack the New Telephone Company's instruments.

ELECTRIC LIGHTING IN TOURS.—A central station for the distribution of electricity by Gaulard and Gibbs secondary generators was opened two months ago in Tours. The last number of our contemporary *Cosmos* contains a detailed description of the opening ceremonies, and also some data on the plant erected, from which we take the following :—Power is supplied by two Weyher and Richemond steam-engines, one of 150 horse-power, running at 70 revolutions per minute, the other of 100 horse-power, running at 80 revolutions per minute. The power is transmitted by link belting to a counter shaft, and thence to the two Siemens alternating current dynamos type W_{100}. These are excited by the D_2 continuous current dynamos. The speed of the main dynamos is 500 revolutions per minute, which gives 16,500 reversals of current in the same time. With the full exciting power they develop an E.M.F. of 2,500 volts, but at present 1,250 volts are used, the current being at present 22 amperes. The mains are laid in underground troughs, and consist of 19-strand 65 mm. wire insulated by rubber, ozokerite, and tarred hemp. It is contemplated to erect 10 secondary generators; but at present only four are in use. Each consists of six primary and six secondary coils, the former being placed in series, the latter in parallel, so that the ratio of conversion is about 1·24, giving a secondary current of about 50 volts and 125 amperes. The four generators absorb each $5\frac{1}{2}$ amperes, and are placed in parallel on the mains. If the figures given by *Cosmos* are correct, the efficiency of conversion would be the ratio of 50×125 to $5\frac{1}{2} \times 1250$, or about 90 per cent.

FINSBURY TECHNICAL COLLEGE.—At a meeting of the City and Guilds of London Finsbury Technical College Old Students' Association, held on Wednesday, March 10th, at the College, Leonard-street, Mr. H. Newman Lawrence in the chair, Mr. W. T. Pettigrew (vice-president) read a very interesting paper on "Lighting of Railway Trains." The author spoke of the importance of the question of efficiently and economically lighting railway carriages, and the necessity of some radical improvement in the present general system. He gave his opinion that railway managers and engineers have very naturally hesitated in entering upon the heavy expense of lighting their carriages upon any other than the ordinary system lest to-morrow a newer and better one than they have adopted should present itself. The different systems of lighting were then enumerated as follows :—The ordinary roof lamp, burning rape or roof lamp oil ; the mineral oil roof lamp, burning highly refined and high-flashing petroleum ; ordinary coal gas ; coal gas compressed ; coal gas compressed and enriched ; oil gas, and electricity. The author then gave a detailed account of the different systems, the construction of the lamps, candle-power of the different lights, and particulars of the oil or gas used, and apparatus and fittings to the carriages. The system of lighting by oil-gas, as fitted to the Metropolitan and Metropolitan District Railways, and altogether fitted to over 3,000 carriages in Great Britain, was then fully entered upon, both as regards the manufacture of the gas and the apparatus and fittings to the carriages. On the subject of the electric light in railway carriages, the many systems on the different railways were described and contrasted, and mention was made of the brilliancy of the light and the conspicuous advantage over other lights, of putting out and relighting so readily without having to apply a light to each lamp. The costs of the various systems were also compared. In the discussion which followed Prof. S. P. Thompson, D.Sc., contributed some useful and interesting information on the subject. The following gentlemen also spoke :—Messrs. A. Chatterton, B.Sc., W. S. Crawshay, L. Davidson, W. Dickson, O. Haes, A. W. Herbert, H. Newman Lawrence, A. C. F. Webb, and N. R. Wilson.

COMPRESSED AIR AS MOTIVE POWER FOR DRIVING DYNAMOS.—In Paris there is a society owning and working a number of clocks distributed throughout the town. These clocks are worked by compressed air, and as it was found necessary to remove the compressing machinery from the centre of the town where most of the clocks are situated, the company were forced to lay down an underground air main, $3\frac{1}{8}$in. in diameter, which happens to pass along some of the boulevards and other principal streets. Advantage is therefore taken to supply motive power not only for the clocks, but for other purposes; and in the Café de Paris there is, according to our French namesake, *l'Electricien*, an installation worked by compressed air from the pneumatic main. The pressure employed varies between 45 to 60lb. per square inch, and the power is regulated by a throttle-valve interposed between the air main and an air vessel, or reservoir, from which the engine is supplied. The object of this reservoir is to prevent the strokes of the piston of the air-engine from being felt in the main. Since the air in passing through the engine works expansively its temperature becomes considerably lowered, and to prevent the formation of ice and snow, which would have the effect of clogging the valves and passages, the air must be heated to about 50deg. centigrade before being admitted to the cylinder. This is done by passing it through pipes heated by a gas stove. The dynamo employed is of the Gramme type, giving 35 to 40 amperes at a pressure of 100 volts when driven at 1,400 revolutions per minute. It receives motion by a belt from the fly-wheel of the compressed air engine, which runs at 150 revolutions. The power is charged for at the rate of 70 centimes (about 7d.) per horse-power hour, but the method of making up the account is, to say the least of it, very primitive. It simply consists in attaching a counter to the engine shaft, and charging according to the total number of strokes made by the piston. With a water engine this would be perfectly fair, but with an engine which works by the pressure of an elastic fluid, first more or less throttled, then heated, and then expanded, the amount of power obtained is in no way proportional to the total number of strokes made during any given time. Whatever be the merit or otherwise of this system of charging for power, the price charged is quite prohibitive, and we cannot well see how it could be otherwise. Of all the known means of transmitting energy to a distance, compressed air is the most wasteful. It would have been much more economical to lay a pair of cables at the same time as the pneumatic tube was laid, and work the lamps in the Café de Paris direct by a dynamo in the compressing station.

PHOTOGRAPHY BY A LIGHTNING FLASH.—According to Prof. E. J. Houston, Mr. Albert S. Barker, of Philadelphia, has succeeded in taking two very fair photographic negatives of outside objects while illumined by no other light than that of a single lightning flash. These photographic views were taken at 7 p.m. on Thursday, October 29, 1885, near Philadelphia. The night was excessively dark, the wind strong, and the rain heavy. The camera was placed in an open window, with the slide drawn. The lightning flash came in less than one minute, when the slide was returned. The plate holder was then

Digitized by Google

reversed and suitably placed for a second exposure. The plate was one of the highly-sensitive gelatine films. Mr. Barker developed the plates the same evening. From their behaviour he rated the actinic effect of the light as equal to that obtained from an exposure of about $\frac{1}{300}$th part of a second in bright sunlight. The popular impression as to the duration of the lightning flash is that it is practically instantaneous. From the experiments of Wheatstone and others with the rotating disc, the duration of the flashes measured would vary apparently from the $\frac{1}{1000}$th to the $\frac{1}{10000}$th of a second. Others estimate the duration of the flash as even shorter than these figures. It is very doubtful if the average severe flash in this latitude does not endure or continue for a very much longer period. Despite the popular belief to the contrary, the author has frequently observed the motion of foliage when illumined by no other light than the lightning flash. This would not of course be the case if the flash were even approximately instantaneous. It is a very significant fact that in the photographs of Mr. Barker the foliage shows unmistakable evidence of having perceptibly moved during the period of exposure; thus showing that it was by no means instantaneous. It is to be hoped that Mr. Barker, or some other photographer, will repeat these exposures under the following conditions, viz., to make the exposure while the camera is sharply focussed on moving foliage, or a rapidly rotating wheel, while illumined by a lightning flash, so as to determine more definitely the duration of the flash. In the case of the lightning flash, the large percentage of blue rays would of course render the plate more sensitive to the extremely short exposure by practically prolonging the same, since the ordinary photographic chemicals now employed are especially sensitive to the blue portions of the spectrum. It would appear from the facts developed by the photographs of Mr. Barker that the method of measuring the duration of the lightning flash as adopted by Wheatstone and others, which consists essentially in endeavouring to detect by the unassisted eye the change in position of a rapidly moving wheel, or other object, while illumined by the flash, might be greatly improved by substituting for the eye the sensitive photographic plate, since the latter is apparently far more sensitive than the eye. Should photographic pictures of a rapidly rotating wheel, whose rate of motion was known, be taken while illumined by a lightning flash, the displacement of the image on the negative would give far more reliable data for calculating the duration of the flash than the methods heretofore employed. Mr. Barker's photographs, therefore, are not only interesting as showing how extremely sensitive the photographic plate may be made, but are also of interest as throwing some light on the possible duration of the lightning flash.

ELECTRIC HOUSE LIGHTING BY PRIMARY BATTERIES.— Numerous attempts have been made to obtain a successful incandescent electric light by means of secondary storage batteries, charged from dynamos, but, owing to the small amount of electricity obtained in comparison with the power required, these batteries have so far, we believe, not been proved to be a commercial success. One of the latest improvements in this direction has been the production of a primary battery, named the "Aurora," which is really an improved bichromate solution battery, having a power which is remarkable for its size, and the advantage of not polarising, heating, or evolving any deleterious gases. Each cell holds about a gallon of exciting fluid, which, we are informed, is made by a peculiar patented process, and is the important factor in the success of the battery. Two large carbon plates are placed outside of the porous cup, and in the latter is inserted the zinc, of a special form to expose a large amount of surface. In the porous cup is put water, which in a few hours becomes charged with the exciting fluid from the outside jar. The zincs are well amalgamated to prevent local action. We recently attended a private exhibition of a complete system of house lighting by the use of this battery, as introduced into the residence of Mr. Henry V. Parsell, of this city, and were agreeably surprised to notice the power of the battery in sustaining with beautiful brilliancy several incandescent lamps, and the facility with which they could be lighted. In a room adjoining Mr. Parsell's laboratory, together with a fine large screw-cutting geared lathe and other highly polished steel tools, were located on shelves twenty eight cells of battery. None of the tools were corroded or in the least damaged by reason of fumes emanating from the battery. In addition to its use as a lighting battery, it was shown that it could be employed as a motive power for driving the large lathe, by means of a small Cleveland electric motor, developing a force equivalent to one-third of a horse power. A special switch was provided, which enabled the operator to utilise at once the force from one to twenty cells, as might be needed. No difficulty was experienced in rapidly boring, with large-sized drills, through blocks of the hardest wood 2in. thick. Many novel uses of the lamps were shown; half a dozen 6-candle lights placed in a cabinet of minerals, when turned on, instantly lighted it perfectly. In a dome in the ceiling of the laboratory, painted blue and decorated with gilt stars, were hidden from view a group of small lamps. These when lighted produced a very soft, radiant effect, giving a light similar to that of a full moon on a clear night. A special small Edison lamp of 40 candle-power placed in a magic lantern was next lighted, and the pictures in the lantern thrown upon the screen. The brilliancy of the light compared favourably with the lime light. A peculiar dark room ruby light, for photographic purposes, was shown, and also the perfect adaptability of small lamps for illuminating safely dark closets. Adjustable lights with neat porcelain shades mounted on a stand for desk use or for reading purposes, as well as suspended lamps, were also exhibited. We were informed that about thirty lamps of varying candle-power had been distributed about the house, but the full power of the battery was not capable of sustaining more than eight sixteen candle-power lights at a time. It was expected that for ordinary use but half a dozen lamps would be used at once. In comparison with the results obtained, the loss of zinc in the battery is exceedingly small. Mr. Parsell stated that although the zincs had been constantly immersed and the battery had been working for two months, the zincs had lost but a few ounces each in weight. He had replenished the battery but once during that time, having used it every day. The advantage of having electricity generated for general use in one's house so easily, and with so little trouble and danger, as this battery appears to furnish it, cannot be over estimated. We understand its practicability has been so well established by prolonged experiment that a new company, with a large capital, called "The Household Electric Light Manufacturing Company," of New York, has been organised for the purpose of putting in electric plants in private residences and caring for the batteries, keeping the same in order. The small lamps, their attachments, and the battery are supplied by the Stout Meadowcroft Company, of this city. The above is from the *Scientific American.* We give it as a fair specimen of "Primary Battery" literature from the other side of the Atlantic, and may say that the praises of the inventor are not warranted by the teachings of science.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 208.)

Action between a Magnet and a Magnet, or between a Magnet and a Conductor supporting an Electric Current. The Closure of the Electric Current. Its Necessity.

The section before the last being preliminary to the subject of the stresses, and the last section being of a perfectly abstract nature, the one to follow this will be on the magnetic stress in general, as modified by differences of permeability and other causes. The present section is of an intermediate nature. Though dealing with the magnetic stress outside magnets, its principal object is to direct attention to the vexed question of the closure of the electric current; which I endeavour, as far as I can, to bring down to a question of definition.

Let us forget, if possible, for a time, all knowledge of the electric current—or rather, let us make no use of it. Suppose that we are fully acquainted with the mechanical actions of rigid magnets upon one another. That there is probably no such thing as a perfectly rigid magnet (that is, in the larger theory, an unmagnetisable magnet, whose permeability is unity, or the same as that of the enveloping medium) is immaterial. We suppose there is. Except that the argument would be more complex, it would not alter our general conclusions to take a magnetisable magnet.

We may put any collection of little rigid magnets together to form a complex magnet, having any distribution of magnetisation. Its external field of force is to be got by observing the mechanical force it exerts upon one pole of an exceedingly weak and slender magnetised filament, uniformly and longitudinally magnetised, so as to localise its poles strictly at its ends. Upon the basis of the definition of a unit pole, that it repels a similar unit pole at unit distance with unit force, we can map out the external field of force. Let F be the magnetic force intensity, the force on a unit pole placed in the field, or rather, n times the force on a pole of strength n^{-1}, when n is infinitely great. F is subject to the conditions

$$\text{div.F} = 0, \qquad \text{curl.F} = 0,$$

outside the magnet. The lines of F start from the surface of the magnet, proceed in curved paths through the air, and end upon its surface again at other places.

If we describe a closed surface in the air, completely enclosing the magnets, of whose position within the surface we might be ignorant, we should be entirely unable from our examination of the field outside the surface, to determine the interior distribution of magnetisation, or even to determine the situation of its poles, that is, the distribution of the imaginary magnetic matter, to which, if we ascribe self-repulsive force according to the inverse square law, we may attribute the external field. We might ascribe F to a distribution of matter σ over the surface itself, of total quantity zero; or to a distribution of a vector quantity γ over the surface in closed lines, producing external F according to another law, viz., $\text{V}f\gamma$ = force due at a point Q to the element γ; f being the force at γ due to unit matter at Q; or to combinations of both σ and γ, one of which is unique, inasmuch as it produces no internal field. Contract the surface until it reaches the magnet itself. Then we may ascribe the external field to σ, or to γ, or to combinations, definitely, on the surface of the magnet, or in its interior in various way, but not definitely. The distribution of magnetisation is, *a fortiori*, still more undiscoverable, for there may be distributions corresponding to no magnetic matter, giving no external force.

But, making use of our knowledge of the effect of building up a magnet from smaller ones, we may suppose that the magnetisation is known. Let the vector magnetisation be I, and its convergence be ρ, the density of the magnetic matter. Then

$$\text{div.F} = 4\pi\rho, \qquad \text{curl.F} = 0,$$

fully determine F. It is of considerable practical utility in theoretical reasoning not to treat the surface and the volume densities separately, but to include them both in ρ, the volume density. Thus, if a magnet be quite uniformly magnetised, there is, strictly speaking, no ρ. The convergence of I is on the surface. But, by supposing I not to cease abruptly on reaching the surface, but gradually, however rapidly, through a thin surface layer, we make the matter have a space distribution, of the same total amount per unit of surface as the surface distribution it represents. We can always derive the surface expressions from those of the volume with great ease, when we want them; whilst our work is much simpler without them when we do not want them.

The resultant force between any two magnets may now be easily represented. $\Sigma F_2\rho_1$ is the resultant force on a magnet whose matter density is ρ_1, due to another magnet whose polar force is F_2. And $\Sigma F_1\rho_2$ is the force of the first magnet on the second. (We need not trouble about the forces of rotation at present, which are nearly as simply represented.) These are equal and opposite. Also $\Sigma F_1\rho_1 = 0$ and $\Sigma F_2\rho_2 = 0$; a magnet cannot translate *itself* (or rotate itself either). So if $F = F_1 + F_2$, making F the actual force of the field, the forces on the magnets are $\Sigma F\rho_1$ and $\Sigma F\rho_2$ respectively.

Describe any closed surface separating one magnet from the other; let the first magnet be inside. The force on it may, as in the last section, be represented by the surface integral

$$\tfrac{1}{2}\Sigma(\sigma\text{F} + \text{V}\gamma\text{F}),$$

if $\sigma = \text{NF}/4\pi$, $\gamma = \text{VNF}/4\pi$, N being a unit normal from the inner to the outer region. Or, which is the same thing, by

$$\Sigma\{\text{F.(NF)} - \text{N.}(\tfrac{1}{2}\text{F}^2)\}/4\pi,$$

in terms of the Maxwellian stress.

The following is the process of showing that this stress gives rise to the required mechanical forces. The quantity summed up is the vector stress on the plane whose normal is N. If we fix the direction of N, its divergence is the N-component of the force per unit volume, by the principles of varying stress.

Now $$\text{div.}\{\text{F.(NF)}\} = (\text{NF})\text{div.F} + \text{F}\nabla(\text{NF}),$$

and $$\text{div.}\{\text{N.}(\tfrac{1}{2}\text{F}^2)\} = \frac{d}{dn}\left(\tfrac{1}{2}\text{F}^2\right) = \text{F}\frac{d\text{F}}{dn},$$

if n be length measured along N.

Also, $$\text{F}\left\{\frac{d\text{F}}{dn} - \nabla(\text{NF})\right\} = \text{NVF.curl.F},$$

so, S being the vector stress on the N plane,

$$4\pi.\text{div.S} = (\text{NF})\text{div.F} - \text{NVF.curl.F},$$
$$= \text{N}\{\text{F.div.F} - \text{VF.curl.F}\},$$

or, $$\text{div.S} = \text{N}\{\text{F}\rho + \text{V}\Gamma\text{F}\},$$

if $\Gamma = \text{curl.F}/4\pi$. This being the N-component of the force, the force itself is

$$\text{F}\rho + \text{V}\Gamma\text{F}$$

per unit volume; or, since $\Gamma = 0$, the magnetic force of the magnets being polar, simply $\text{F}\rho$ per unit volume.

The length of this process depends upon our wishing to develop the term $\text{V}\Gamma\text{F}$. If it were not for that, we would see at once that

$$\nabla(\text{NF}) = \frac{d\text{F}}{dn}$$

when F is polar, N being in any direction, and so get the force $\text{F}\rho$ immediately.

The question now asks itself (remembering that we are ignorant of the electric current), what is this Γ, whose vanishing cuts the work short at the beginning, in our case of F being polar. Can it really represent any physical magnitude?

It is defined by curl. $\text{F} = 4\pi\Gamma$, and is necessarily zero in the case of magnets. It indicates *closed* lines of F, which are impossible with a strictly polar force in all space Γ is a vector, and is necessarily closed. This is a mathematical consequence of its definition.

Furthermore, whilst F, as a polar force, with $\Gamma = 0$, is a special kind of distribution of a vector, if we allow Γ to be not zero F becomes of the most general type possible, *any* distribution of force, or any field of force, without the polar limitation. Given the divergence, and the curl of a vector, the vector itself is fixed, if it is to vanish at infinity.

Digitized by Google

Supposing, then, we allow that Γ can exist, we can predict what the mutual force between a magnet and it will be. Let there be Γ in a certain region, outside of which there is only ρ, therefore only magnets. The resultant force on this region is equivalent to VΓF per unit volume. We cannot localise the force, we can only know its total amount. It is necessarily ΣVΓF. The reason we cannot say that VΓF is the force on unit volume is that Γ is necessarily closed, and so we cannot work down to a unit volume without having current in the external region as well, which is against our previous knowledge.

So far Γ has a merely speculative existence. It is got by making the assumption that there can be closed lines of magnetic force. Admit that there can be, the laws of Γ follow. Γ is necessary closed. The magnetic force it produces at Q is $\Sigma f\Gamma$ if f be the force at Γ due to unit matter at Q. The force between one Γ and another and between Γ and ρ follow, viz., that the resultant force on any region containing ρ and closed Γ is

$$\Sigma(\rho \mathrm{H} + \mathrm{V}\Gamma\mathrm{H}),$$

H being the actual intensity of the field due to all the ρ *and* Γ.

Now, we do know what Γ is, under certain circumstances. By the researches of Ampère, the father of electrodynamics, who gives his name to the père, the unit of electric current, we know that Γ measures the density of current in a conductor when it is steady. His researches were conducted in a very different manner, and are indeed very difficult to follow, like most novel researches, but the results are exactly these, without his hypotheses as to the action between different elements of a current. We virtually measure the strength of current in a conductor, when we use a galvanometer, by the line integral of H round a current, and that is the amount of the quantity $\Gamma = \mathrm{curl.H}/4\pi$, passing through the line of integration.

Also, steady currents are closed. So far, then, we identify Γ with the conduction current.

But *our* Γ is closed under any circumstances. We know also that conduction currents are not always closed; for instance, when we charge a condenser. We still measure the conduction current in its transient state by Γ. We do so by the continuously changing instantaneous magnetic force if the charge or discharge be slow enough; otherwise, by the ballistic method, which is virtually the same. Γ being then unclosed in the conductor, has necessarily its exact complement, to close it, outside the conductor, *i.e.*, our Γ has, though it may be only called current when in the conductor.

But our Γ, being identified with current when in a conductor, both in steady states when the current is closed in the conductor, and in transient states when it is closed through the dielectric, and this Γ in the dielectric being related to the magnetic force in the same way as if it were conduction current, why should we not call it electric current also? As it demonstrably exists, we see that the closure of the current is reduced to a question of a name. It would be positively illogical not to call it electric current.

To sum up.

1. From magnetic knowledge only, there should be no closed lines of force in the space outside magnets.
2. If we admit the existence of closed lines of force, or say generally, if we admit that the line integral of the force in a circuit in air can be finite, we arrive at a vector quantity Γ having the property of being closed, and we can find the mechanical force between it and magnets or other Γ, and can thus definitely measure Γ.
3. This Γ we know to be conduction current, when steady.
4. But in transient states, conduction currents are not closed (or need not be).
5. But a part of Γ still measures the conduction current.
6. The other part, the complement of the conduction current, is outside the conductor, continuous with the conduction current, and closing it.
7. Then why not call it electric current?

We see that it is not a question for experiment, for no amount of experimenting could alter this reasoning, but of definition, an agreement to call a certain function of the magnetic force always by one name, viz., the electric currrent, which, if in a conductor, heats it and and wastes energy, whilst in a non-conductor does not, energy being stored potentially. It is, of course, needless to add that this current in a non-conductor is Maxwell's current of displacement, $\dot{\mathrm{D}}$, the rate of increase of the displacement, whilst $\mathrm{E}\dot{\mathrm{D}}$ is the activity of the electric force E to match, and $\frac{1}{2}$ ED the stored potential energy of displacement.

NOTE on equation (32*a*), p. 207, Jan. 22, '86.—For mnemonical purposes, the following is a concise form of this equation. The potential being given $= \mathrm{P}_0$ over a closed surface, due to matter or current within or on it, the potential P at any external point Q is

$$\mathrm{P} = -\Sigma p^2 \frac{d}{dn}(\mathrm{P}_0/p), \quad . \quad . \quad . \quad . \quad . \quad . \quad (32a)\ bis.$$

if p be the potential due to unit matter at Q, and n be length measured along the normal outward.

(To be continued.)

MUNCASTER CASTLE INSTALLATION.

At a time when the sun has passed the equator, and when a genial warmth has replaced the wintry temperature of the early part of the month, our readers can hardly realise the troubles and privations undergone in a journey to Muncaster Castle on the first two days of March. Cumberland under a canopy of snow presented a scene at once weird and beautiful. From the experiments carried out at Messrs. Mather and Platts, at Manchester, we were bound to Ravenglass, the nearest station to Muncaster. Our colleagues at Manchester little knew the lucky escape they would have when parting for the South and for home on Saturday, Feb. 27th. When the hospitable doors of Mr. W. Glover closed on us on Sunday night the wind was bitterly cold, and snow was beginning to fall, while on Monday morning the storm had commenced in stern reality. March, indeed, came in like a lion. Before starting northward we paid a hurried visit to two of Mr. Glover's works; we hope shortly to visit the third, and to give a description of the same. Starting from Manchester we soon found that the snow would assert its supremacy. Everywhere it was drifting, and the train service was becoming more and more deranged. Despairing of getting to Ravenglass we decided to stop at Ulverston, and again fate was in our favour, for between Barrow and Ravenglass two trains were snowed up. One line was with difficulty got clear on the Tuesday, and we had the pleasure of passing the snowed-up carriages on the other line. Arrived at Ravenglass, we found it a little seaside village without much accommodation for man or beast. It seemed that even when within a mile or so of our ultimate destination that we must turn back, but fortune, in the shape of a two-horse buggy, in which was seen the genial face of Mr. Richardson (Messrs. Robey and Co.) came to our aid, so that the last difficulty was overcome. The correspondents of the political papers undergo privations to obtain authentic news, and we think we can claim that the correspondents of the technical press do not spare themselves in order that they may verify the facts of an installation. It is easy to accept descriptions and give them publicity, trusting wholly for their correctness to the sender, who is generally a greatly interested party, but not so easy to verify the facts before subscribing to their accuracy. The gentlemen who met at Muncaster Castle on March 2nd must always feel some sort of contempt for the "drawing room soldiers" who take things on trust. However, Edinburgh, London, Lincoln and Manchester met amid the snow drifts, and proceeded to explore the castle. If we have adverse criticism to make, let us make it at once. Opinions may differ, and do differ considerably, upon questions relating to ornament and light, and, therefore, we may be allowed to say that the fixed standards in the hall seem to us far from being the best means of placing the lights; and although candles are always placed upon the table in the dining room, it would be better to have more lamps. Two clusters could be placed overhead, and kept in perfect harmony with the arrangement of the room. Lastly, so far as suggestion is concerned, we think the whole benefit of the

Digitized by Google

light is not obtained upon the table in the billiard room. Have lamps with the top half silvered been tried, and, if so, with what result?

The greatest admiration was expressed for the electrolier in the library, and without doubt it is one of the most elegant and tasteful that we have ever seen. It is made of polished copper in the form of sprays and flowers, each flower carrying an incandescent lamp. The lamps are so arranged that one-third, two thirds, or the whole number can be switched on or off, as desired. The electrolier was made by Messrs. Edmondson and Co., of Westminster, who carried out the whole installation, from designs of Mr. Ferguson, the architect of the castle. From the castle to the engine house was the next move, in order to try some experiments with the engine, and more especially with its governor.

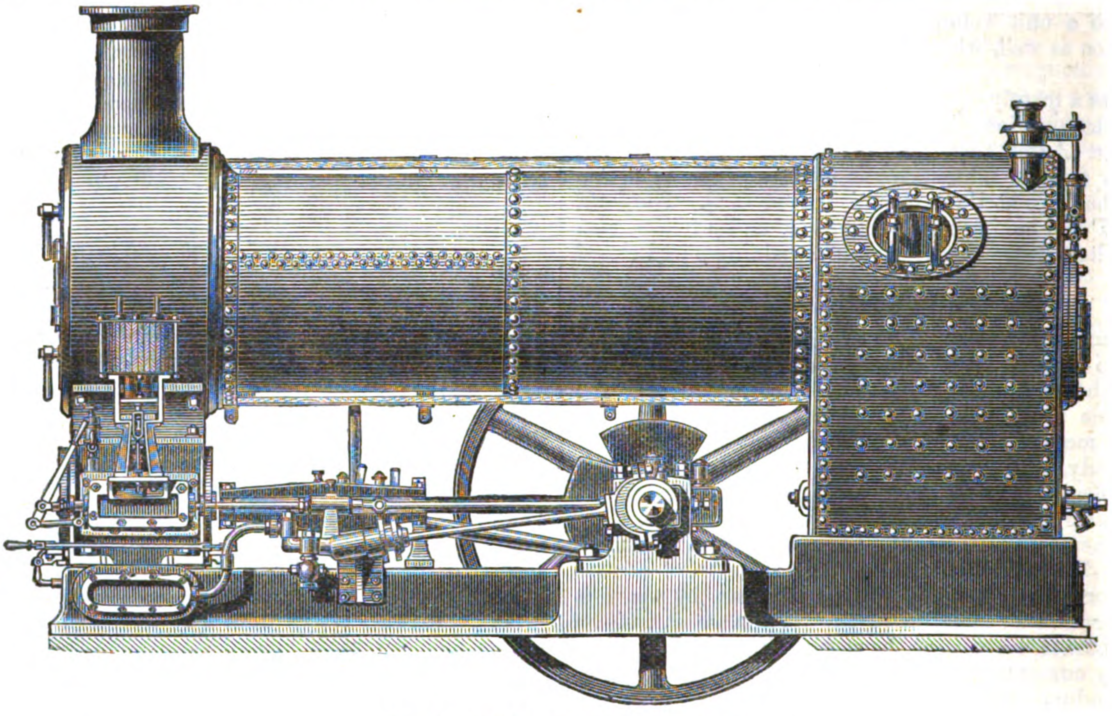

FIG. 1.—"Robey Engine." Side View.

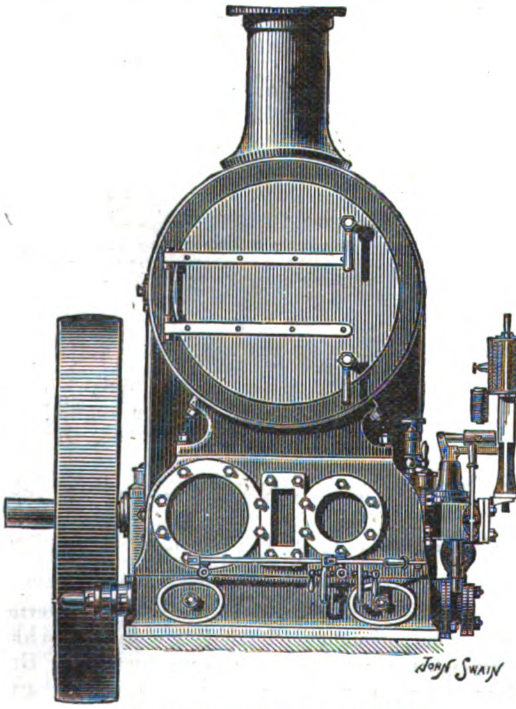

FIG. 2.—"Robey Engine." End View.

The experiments, which were highly successful, were made to test the efficiency of the Richardson-Nevile electric regulator, which was exhibited and described at the summer meeting of the Institute of Mechanical Engineers held at Lincoln last August (*vide Electrician*, Vol. XV., pp. 235-6, 252-3).

The installation at Muncaster Castle, as we have said, was made by Messrs. Edmondson, and consists of two Elwell-Parker shunt-wound dynamos, each capable of supporting 120 lights of 16 candle-power. Practically the whole of the castle is lighted by electricity.

The machines are driven by a steam engine of 14 horse-power nominal, made by Messrs. Robey and Co., of Lincoln. The engine has two cylinders, 8$\frac{3}{4}$in. diameter by 14in. stroke, fixed on a massive cast-iron base plate, which also supports the boiler, and is of the type now so well known as the Robey engine (Figs. 1 and 2). The engine is not only used for driving the dynamos, but also for sawing wood, &c., for the estate, for which purpose it is fitted with an ordinary high-speed governor, controlling a double beat valve. When used for electric light purposes this governor does not come into play, the engine being then controlled entirely by the Richardson-Nevile electric regulator.

It may be well to refer briefly to the combined governor, which is illustrated in Figs. 3 and 4. The regulating part of the governor consists of a double solenoid magnet M M, placed vertically, and wound with insulated copper wire, within which works a double core, A A. To the cross piece D, at the bottom of the cores, is linked the long arm of the lever E, the short arm of which presses downwards upon the spindle of an ordinary double-beat Cornish equilibrium valve that controls the admission of steam to the chest. For incandescent lighting in parallel the wire on the bobbins is placed in shunt circuit between the main leads, and the size of wire is adjusted to the electromotive force it is desired to maintain between the mains; when the proper electromotive force is attained the cores A A are suspended within the solenoids by their attraction. Since the resistance of the solenoids is fixed, any increase in electromotive force causes an increased current to flow through them, and consequently the cores are attracted with increased force, and are drawn upwards, thereby closing the equilibrium valve a little, and reducing the steam supply until the electromotive force has been brought down again to its proper value. So far as here described the governor is very imperfect, allowing of too much variation (especially under variable boiler pressures) in electromotive force, which is very destructive to the existence of the lamps. To remedy this defect the small

Digitized by Google

cylinders B and C seen in Fig. 3 are added. Each cylinder is fitted with a small piston and rod, the tops of which engage with a lever L, but on opposite sides of the fulcrum. The cylinder B communicates by means of a small pipe with the boiler, and the cylinder C with the steam chest. This arrangement very accurately neutralises the effect of a variation in the boiler pressure by opening or closing a little the throttle valve, as the case requires, and in that way a constant steam chest pressure is maintained, whatever the pressure in the boiler may be, so long as it is enough to keep the machines going at their proper speed. The cylinders B and C can be moved nearer to or further from the fulcrum of the lever, so that the resultant effect of their differential action can be accurately adjusted. The centrifugal governor shown is added for safety in view of a wire breaking or of the main driving belt leaving the pulley; of course, if, as in this case, the engine is used for other work, it is absolutely necessary that a centrifugal governor be applied in addition to the electric regulator. A high testimony to the value of the apparatus consists in the fact that though it was set to work over six months ago and left in the hands of an ordinary engine driver it has continued to work most satisfactorily, and was found by the gentlemen who witnessed the all the lights were turned on the effect on the engine was equally instantaneous. These experiments were many times repeated, always with the same results. It is certain that a momentary change must really take place when large numbers of lamps are switched in or out, else no effect could be produced upon the engine, for "out of nothing nothing can come." To ascertain this amount was the next object. The voltmeter was kept in the circuit and carefully watched by one gentleman, another as carefully observing the time, whilst a third manipulated the switch. A signal being given, the lamps on all switched out, the voltmeter needle makes a sudden upward movement, instantaneously changes its direction, and comes gradually to rest again. The maximum variation, and that only for an instant, was not more than 5 per cent., and the whole time occupied by the regulator in shutting off steam from the engine and bringing the E.M.F. to its normal intensity did not exceed 3 seconds, the speed of the engine being reduced from 143 to 123 revolutions within that time. Similar experiments were then tried with the accumulators, with equally satisfactory results. The next test was made to show how far the boiler pressure could be raised without affecting the speed of the engine, the load remaining constant. Steam was allowed

Combined Electrical and Centrifugal Governor.

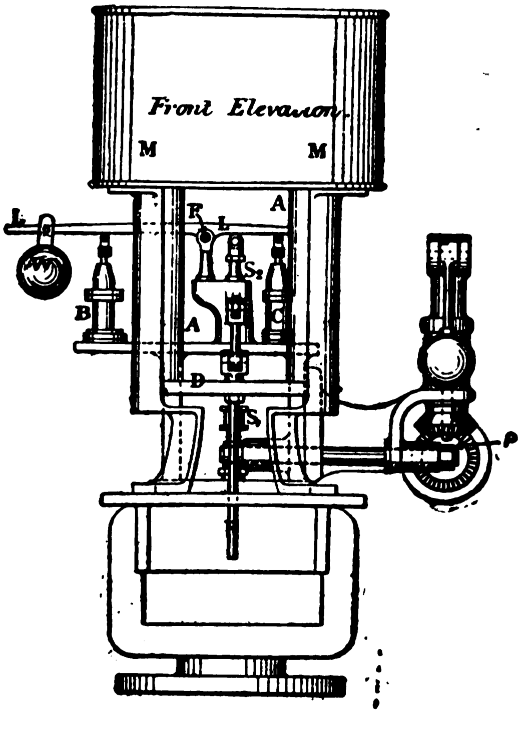

Fig. 3.

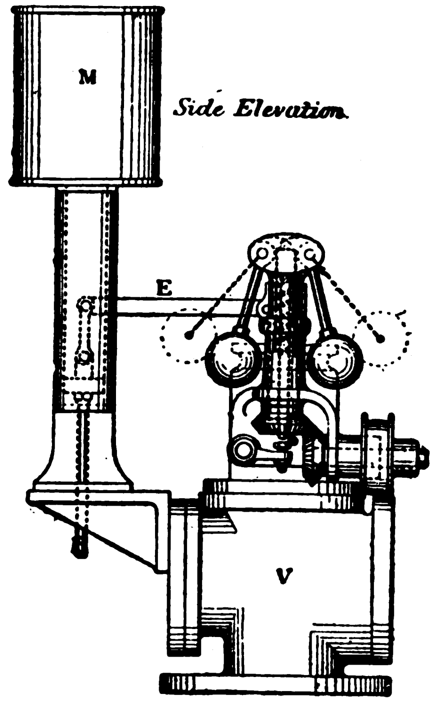

Fig. 4.

tests in a state of the highest efficiency. The tests made at Muncaster were as follows:—The engine was started, running the dynamo with one lamp only burning in the engine room. A man was then sent round the castle to turn on the lights, as would be done in ordinary use, while the voltmeter was carefully watched to see the effect upon the electromotive force. This remained constant at 120 volts, it being impossible to detect the slightest variation. The engine, as the lamps were turned on, increased in power and speed, the intensity of each light remaining constant. Groups of lights on the brackets and electroliers in tens, twenties, and thirties were turned in and out without making any perceptible change in the electromotive force. A most severe test—probably the most severe possible—was then tried. All the lights which could be lighted were turned on, and by a switch in the engine house all turned off at once. Simultaneously with turning the switch the click of the slide valve was heard in the steam chest, showing conclusively that all the steam had been shut off, and that the engine was running empty. Examination of the voltmeter before and after showed no difference in the E.M.F. When to run down from 75 to 40lbs. pressure and run again to 80lbs., the speed of the engine remaining constant within one revolution. It was remarked that, though the regulator acted with most remarkable promptitude or suddenness, there was not the slightest tendency to overrun or hunt.

We certainly must congratulate Messrs. Robey and Co. upon the success of these experiments, and Mr. Richardson for the admirable governor he and his colleague have devised.

The Economy of Small Arc Lights.—German *savants* continue to experiment with small arc lamps, which German electricians are continuously bringing forward. Dr. Valler, in Hamburg, has recently examined the small arc lamp of Scharnweber, intended for a current of about 4 amperes, and he finds that at an angle of 45 degrees to the horizontal, 483 English standard candles are obtained with an expenditure of 196 watts. The average between the horizontal intensity and that at 45 degrees is 315 candles, obtained with an average expenditure of 200 watts. This is at the rate of 0·63 watt per candle.

ANSWER TO CORRESPONDENT.

A. F.—*We cannot call attention to the note you refer to, as by so doing we should be perpetuating the evil. We quite agree with you as to the bad effects and the undesirableness of such notes.*

THE SIXPENNY TARIFF.

If any proof were needed of the general popularity which the SIXPENNY TARIFF for INLAND TELEGRAMS has already secured, it would be furnished by the ASSOCIATED CHAMBERS of COMMERCE. That body of commercial representatives are not famous for modesty in preferring their claims to consideration, or for moderation in propounding their grievances. A deputation from them waited on the POSTMASTER-GENERAL a short time ago to state their views on the new tariff, and also as to the charges for telephonic communication. With regard to the latter we have nothing to say at present, further than to agree with Lord WOLVERTON that the question is a great deal too large and complicated to be dealt with, except by a gigantic addition to the business of the Department entirely beyond the sphere of practical politics just now. But with respect to the first-named subject, namely, sixpenny telegrams, all that the deputation could find fault with was the, in their opinion, excessively high charge for registering addresses. Subsequently a memorial reached the POSTMASTER-GENERAL from Yorkshire, equally limited in the scope of its complaint, proposing only that this charge should be reduced from a guinea, the present fee, to five shillings. With the exception of the customary newspaper correspondence in the autumn months, most of which came more properly under the head of facetiæ than of serious remonstrance, this is substantially the main fault that has been found with the scheme inaugurated last October; and this only from one class of the community, the class not solely or chiefly considered when the change was advocated. From the general public there have been extremely few complaints, and none at all of the two essential features of the tariff, its brevity and its taxed addresses.

Now this we consider is a great triumph for the originators of the reform; and our testimony ought to count for something seeing that we were never very ardent believers in the blessings of cheap telegraphy, though for many years we were the only newspaper that consistently advocated the abolition of the free addresses. The reduction of the initial charge from one shilling to sixpence was a bold step, which, if popularity is proof of success, has succeeded perhaps beyond expectation, especially as it was coupled with such a reduction in the number of words as might not improbably have been resented as irksome and unnecessary. All has gone smoothly, however; the public have cut down their telegrams to the sixpenny dimensions with pretty general regularity, and when this could not be accomplished they have paid the trifling extra charges with commendable good temper. Added to this, the traffic has been disposed of with wonderful celerity; at least, we infer as much from the absence of public complaints on this score, a circumstance which, considering the enormous increase in the number of telegrams we know to have been despatched, reflects much credit on the POSTAL TELEGRAPH ADMINISTRATION, as well as on the sagacity of those who stood out against the alternative scheme of free addresses with a tariff so low as sixpence.

Had free addresses been conceded, it is highly probable that the provisions made for dealing with the augmented business would not have satisfied the requirements to nearly the same extent. But besides this there must have been a greater loss to the revenue as well as an increase in outlay on plant and in working expenses. As it is we hear of a not inconsiderable falling off of receipts during the past six months, compared with a corresponding period under the old tariff. This is no more than was expected, at all events by persons who took trouble to consider the matter seriously. It will be a good while, we fear, before the British Public double the number of their telegrams all round; and until they are nearly doubled the revenue will show a deficit—a diminishing deficit, no doubt, but still a deficit; and the expenditure we may be sure will go on swelling in nearly the same proportion. Neither in private firms nor in public departments can vast additions to the business be made without a commensurate addition to office expenses. Already we hear of demands being made for increased pay in consequence of the increased work and responsibilities thrown upon the staff of *employés*; and we do not see how these demands can be justly refused on principles which prevail in all ordinary business relations. It was perfectly well understood by those who agitated for this great change in the telegraph system that it was made for the good of the country generally, that the Post Office had no business to earn a profit, and that the benefits conferred on the public by a cheap system of communication by telegraph would far outweigh any loss that might be inflicted on the Post Office revenue. We need not argue these points; but the most fanatical exponent of a cheap Governmental service will hardly venture to assert that servants employed by the Government ought to accept these high philanthropic, philosophic, or politico-economic motives in lieu

Digitized by Google

of pay. Granting the general good, and dismissing, as we have done, the theory of working for profit, it is the more evident we must pay the public servants adequately for enabling us to confer this boon on the community.

No doubt when it comes to be known exactly how the finances of the telegraphs stand in regard to the new tariff, the usual flood of suggestions for mending matters by making them worse will be poured in. We can only hope that they will be dealt with in the same firm and business-like manner with which the deputation from the ASSOCIATED CHAMBERS OF COMMERCE were disposed of the other day. Undoubtedly the charge for registering addresses seems a very high one ; and if it covered only the act of registering, it would, of course, be preposterously so. But it ought to have been pretty evident, even to the Chambers of Commerce, that addresses are registered by persons only who receive many telegrams, and that many references to the registry involve a great deal of time and labour. We have no practical knowledge of the system, and do not mean to have any. The outlay of a few halfpence at most will make our address perfectly intelligible, and will ensure swift delivery without a preliminary search in the Post Office Register of Addresses. But for those who fancy the luxury of having an unintelligible code for their addresses with the idea of saving something the system will last so long as they find it pays. By some it is evidently thought to be a good advertisement ; and it is cheap for them at a guinea. For the rest it is a barefaced evasion of the taxed addresses ; and the request to reduce the charge to five shillings means neither more nor less than that the Department shall abrogate that rule in favour of particular firms. We are glad to see that the POSTMASTER-GENERAL met the request with a flat refusal, pointing out that the system of registered addresses, which may be fairly legitimate for expensive foreign telegrams, is an abuse of the cheap inland tariff, and involved the Department in a loss far exceeding the total number of guineas charged. Perhaps after this the gentlemen represented by the Chambers of Commerce will be discreetly silent on the subject of registered addresses, otherwise they may find that a class privilege which they are now enjoying at the public expense will be in danger of being withdrawn altogether.

CORRESPONDENCE.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In his last letter Prof. Thompson seriously protests against the persistency with which I adhere to what he is pleased to call a wrong definition. Persistency is certainly not a fault of Prof. Thompson, for so soon as he finds that one of his statements has become untenable he qualifies it by saying he meant something else. Thus, in his letter published in your issue of the 5th of March he speaks of a magneto machine having a critical speed. To a plain-speaking man a magneto machine means one with permanent steel magnets, but in his last letter Prof. Thompson explains that he means a machine with steel magnets, provided with series-exciting coils—that is, a dynamo which is partly self-exciting. Only if that was his meaning from the beginning he ought, in his definition for critical speed, to have included the resistance of the series coils. This he has not done. He spoke of the " line that represents (by the tangent of its slope) the armature resistance." But even accepting his latest definition I cannot help thinking that the term "critical speed" is ill chosen. I should prefer to call it the proper working speed, for it is that speed at which the machine will do what is claimed for it by the term self-regulation, *i.e.*, it will keep a constant pressure at its terminals. I shall not follow Prof. Thompson in his elegant simile concerning the sole of his boot, as I prefer to discuss scientific subjects in scientific language ; but dropping all squabbles about phraseology, I shall, with your permission, go back to the point where I had originally the misfortune to differ from Prof. Thompson. It was not a question whether the term critical speed was correct or not, but it was a question whether constant current motors could be made to run at a constant speed if constructed on the basis of Prof. Thompson's formulæ. I shall endeavour to show that a constant current motor cannot be made self-regulating in the way suggested. The condition of supply is : a constant current, whatever may be the counter electromotive force of the motor. The working condition is : a constant speed under a variable load. Since the current supplied to the motor is constant, the work obtained from it must be approximately proportional to the electromotive force at the brushes. That is to say, the heavier the load the greater must be the E.M.F., provided the condition of constant speed to be fulfilled. From the latter condition it also follows that the torque must be proportional to the work done, and therefore it must be proportional to the E.M.F. Since the torque is the product of armature current and strength of field, we find that the latter must be approximately proportional to the E.M.F. Now, Prof. Thompson classifies motors for constant current under these three headings :—

(*a*) Magneto motor, with shunt regulating coils.
(*b*) Series motor, with shunt regulating coils.
(*c*) Series motor, with long shunt regulating coils,

and he proceeds to say that the latter two, with differential winding, are the only important cases.

From his formula it appears that the shunt coils must tend to demagnetise the field. A motor constructed on these principles would therefore have the weakest field when the E.M.F. at the brushes is a maximum, and the strongest field when the E.M.F. is a minimum. Now, I have just shown that the speed can only be maintained constant if E.M.F. and strength of field are approximately proportional, and since the differential winding recommended by Prof. Thompson has exactly the opposite effect, it seems tolerably certain that his motor will not be self-regulating. But even were both series and shunt coils to magnetise the field in the same direction, the motor would not be self-regulating ; for an increase in the load would in the first instance slightly reduce the speed, and this would subsequently result in a reduction of the strength of the field, which again will lower the speed, and so on. A motor so constructed would work in a condition of unstable equilibrium.—Yours, &c., THE WRITER OF THE REVIEW.

Erratum.—In Prof. Silvanus Thompson's letter in our last issue, on p. 369, lines 21, 22, first column :—

For " It has nothing whatever to do with the original and incorrect statement of my reviewer ; the right figure should be 736," *read,* " It has nothing whatever to do with the original and incorrect statement of my reviewer *that* the right figure should be 736."

PARALLEL DISTRIBUTION BY TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In the course of the last few weeks Prof. Forbes, as well as some other gentlemen, have ventilated the advantages and disadvantages of connecting inductional transformers for alternating electric currents in multiple arc with the high tension mains.

We are glad to see that some of the writers on this subject agree in their views with those held by us for a considerable time, and also that the scientific side of the question is becoming the subject of investigation by men of science. But as to the industrial side of the question we beg to state that the connection of alternating current transformers with their primary coils in multiple arc, and supplying the same with alternating currents of sensibly uniform tension, is the subject of our English patent No. 3,379, dated 16th March, 1885, and that the same is patented to us in Germany and in most industrial countries of the world. We are also determined to

Digitized by Google

defend our rights relative to this invention with all the means provided by law.

We request you kindly to publish this communication in the next issue of your esteemed journal.—Yours, &c.

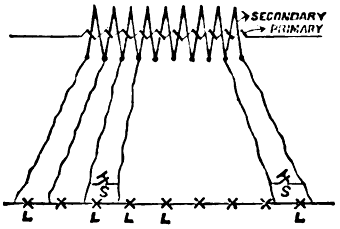
CHARLES ZIPERNOWSKY,
MAX DERI,
OTTO TITUS BLATHY.

Budapest, 18th March, 1886.

THE GROSVENOR GALLERY INSTALLATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 5th inst. you say, in relation to the Grosvenor Gallery Installation, "the lamps are connected to the transformers in parallel, and as they are turned off the potential rises." Could this not be obviated by connecting up the lamps to transformer as in the following sketch:—



S, S are *short-circuiting switches*, there being one to each lamp, L. Lamps L are connected on "the three wire system," and want *very few volts* and *large current* to work them (such as Bernstein's for example). A branch for one lamp (only) is taken off every sixth convolution or so.

Switching out one lamp by shortcircuiting it would, as I understand it, *have no effect whatever* on the other lamps in the series; it would also be highly economical.

The construction of these transformers would readily allow these connections to be made. I should also say that there would not be much difficulty in modifying the present connections to lamps.

If you think the above suggestion worth inserting in your valued paper, I shall feel obliged.—Yours, &c.,

A. M. TAYLOR.

3, Clifton-terrace, Southsea, Hants., March 18, 1886.

MISTAKES IN ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. James Johnstone's question under this head in your previous number, I must first point out to him that the expression—"development of electricity"—which he quotes from my article means neither more nor less than the *production of electrification*, viz., the process by which the distribution of electricity is altered in such a way as to enable it to produce visible effects. I should have thought that this was sufficiently clear from the paragraph immediately preceding the expression quoted.

Now, in order to produce such an alteration in the distribution of electricity in any system a certain amount of work must be done, and, therefore, some source of energy is requisite.

Again ("Maxwell's Electricity," Vol. I., page 46, second edition), if a small body, carrying a small charge, e, be moved from one given point, A, to another, B, along a given path, it will experience at each point of its course a force, R e, where R varies from point to point of the course. Let the whole work done on the body by the electrical force be E e, then E is called the total electromotive force along the path A B.

From this definition of electromotive force we see that a quantity of energy may be expressed as the product of the two factors, quantity of electricity and electromotive force. It is, impossible, then, that electricity should be energy, as it is only one of the factors of energy, the other factor being electromotive force.

Mr. Johnstone's misapprehension evidently arises from his confounding electricity with electromotive force. From his statements, "According to this paragraph, electricity is a *force*, and it is *energy*," it would appear that he supposes force to be the same thing as energy, and also that he is unaware that electromotive force is not a force at all, but that it has been so named owing to the analogy between its action on electricity and the action of force upon matter.—Yours, &c.,

G. W. VON TUNZELMANN.

FRANKLIN INSTITUTE TESTS ON INCANDESCENT LAMPS AT PHILADELPHIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Mr. Tatham's letter in reply to ours on the above tests, we are sorry that we did not see Mr. Wahl's letter in the New York *Electrical Review* of June 20th, which, however, we consider a somewhat weak denial in face of the strong assertions made by the *Electrical Review*.

Mr. Tatham states in his letter:—"In the conduct of the tests the cardinal principle was to do right and also to *avoid all appearance* (the italics are our own) of wrong-doing. To this end a code was adopted and judges selected, with the full concurrence of the contestants, and nothing was concealed from the parties in interest. The contestants were invited to inspect and did inspect every step in the progress of the tests, and their experts compared the photometric measuring powers of the judges with their own."

We are surprised at the Franklin Institute again making the above assertions. We beg most emphatically to deny that a code was adopted or judges selected with our concurrence. We deny that we were ever informed of what was in progress, and we were never invited to inspect, nor did we inspect any steps in the progress of the tests; nor had we experts to compare their photometric powers with that of the judges, but on the contrary, never heard a word of our lamps being tested until we saw in the London *Electrical Review* that the tests were practically over. Mr. Tatham is incorrect when he says the "boast of our lamps is that they are brilliant and cheap." To advocate them on account of their brilliancy would be manifestly absurd, and so far as cheapness goes, although our lamps are the same price to the general public as those of other makers, the trade are willing to pay and do pay a higher price for them than any other lamp. What we claim is that the efficiency of our lamps will be found considerably greater than that of other makers, while the life of our lamps compares very favourably with them.

With regard to the method adopted by the committee of running our lamps five volts higher than they were marked, we think that some statement should have been made of the fact that for some considerable time the lamps were run at from 25 to 32 candle-power, or an efficiency of about $2\frac{1}{4}$ watts per candle-power (mean horizontal intensity), and yet in their report the committee use the words "possibly received more than their proper E.M.F." In the face of the above, these words present a needlessly incorrect view of the case.

With regard to Mr. Preece's statements, he had ample opportunity of testing the lamps at the Wimbledon trials, where they were run for some considerable time, our lamps being, we believe, the only ones of which none broke the whole time. As for the statement that some of the lamps were sent over by Mr. Preece specially to be tested by the Franklin Institute, the following is Mr. Preece's reply to our letters:—

"Gentlemen: The lamps tested at Philadelphia appear to have been some of yours, sent by me to a personal friend, who omitted to give me the faintest idea of the purpose for which they were intended. Had he done so I should, of course, have told you. I had the pleasure of inspecting an installation recently where your 20-candle lamps have obtained an average life of 1,500 hours, and many of them are now 'alive and kicking' after 4,000 hours' work. They were 80 volt lamps, running at 79 and taking 73 amperes, or 56·7 watts each.—Yours faithfully, (Sgd.) "W. H. PREECE."

As we have every confidence in our lamps, we are only too

Digitized by Google

anxious to have them tested in competition with those of other makers, and we shall be happy to subscribe £50 towards any tests such as mentioned lately by Mr. Crompton.—Yours, &c., WOODHOUSE AND RAWSON.

E.P. STORAGE CELLS.

The following interesting letter of Sir William Thomson to the secretary of the Electrical Power Storage Company will be read with interest :—

DEAR MR. DRAKE: Your storage cells have given me the greatest satisfaction. I have used 44 of them for my house lighting ever since I got them first charged up, within a few days after receiving them from you (Nov., 1885), and they have worked to perfection. It is the greatest possible comfort to us in the house to have the light with satisfactorily equal brilliancy at all hours of night or day and every day of the week. I have now cut off the gas at the meter, so that there is absolutely none used in the house. I have no oil lamps, and have not used so much as a single quarter of a candle within the last three months, as I have the electric light in every part of the house where light can possibly be wanted by night or day. I find by a little management of throwing off a few cells from the house circuit when the engine is going, and throwing them on when it is stopped, that there is no difficulty in keeping the potential at the house within 2 or 3 per cent. of absolute constancy.

I use a Clerk gas engine to drive the dynamo, and find that it is impossible to tell by the appearance of the lamps whether the engine is going or not. Before I had your secondary battery we could always see a pulsation of the lights in time with the revolutions of the engine. The absolute steadiness of the light which we now have is most satisfactory and pleasing.

I have six of your cells continually in use on my laboratory table, and they are charged according to need by joining them up parallel and putting them into the charging circuit; so that when they are being charged the engine is called upon to work against a potential of 45 cells, instead of, as usual, a potential of 44 cells. This makes scarcely a sensible difference to the engine; it merely lets it go a little faster and causes it to give a slightly smaller current. Of course, a sixth part of this charging current passes through each of the laboratory cells. I use these cells for laboratory purposes, sometimes keeping them joined in parallel and sometimes joining them in series, according to my laboratory needs. It is a great convenience to me to be able to get at any moment 180 amperes for testing and adjusting my electrical measuring instruments. With this varied and irregular use in my laboratory the six cells keep in perfectly good order. I suppose if I take care never to run them down too low they will keep in good order for years.—Yours truly, WILLIAM THOMSON.

16th March, 1886.

NEW ARC LAMP FOR SMALL CANDLE-POWER.

We illustrate in Figs. 1, 2, 3, and 4 a new arc lamp manufactured by Buss, Sombart and Co., in Magdeburg, which is intended for all cases where a small unit of light is required. It is claimed for this lamp that it can be placed either in parallel or series connection, and will work equally well in either case. The peculiarity of this lamp consists in a special feeding arrangement by which a too rapid descent of the upper carbon—a common failing in ordinary clutch lamps—is rendered impossible. The current enters at *p*, passes through the body of the lamp to the upper carbon, thence across the arc into the bottom carbon, from there through the electromagnet A and out at *n*. The top of the wheel frame, *a a*, constitutes the armature of the electromagnet, and in being attracted raises the rack rod and strikes the arc. In order that the lamp may feed, the train of wheels M, N, O must be set in motion, but it will be noticed that the latter wheel can only rotate through a limited angle, since one or other of the two pegs projecting from its face is arrested by coming in contact with one of the lappets *e e'*, attached to a spindle, P, which carries a comparatively heavy fly-wheel, Q. The usual shunt solenoid, B, in combination with a lever, H, and brake, I, operates the feed motion. When the wheel frame is first pulled up, I presses upon Q, preventing its rotating, but should the arc lengthen, and thus the power of the shunt-solenoid increase beyond its normal amount, the core C will be sucked further in, thereby raising the lever H and brake I, and thus allowing the fly-wheel to revolve in obedience to the pressure exerted by one of the pins in wheel Q upon one of the lappets on the spindle P. When the wheel Q has turned through about 90 degrees, the opposite pin comes into contact with the other lappet, whereby the rotation of the fly-wheel is stopped and reversed. After a further rotation of 90 degrees the second pin slips off the lappet, and the first pin is brought into contact with the first lappet, and so on, the motion proceeding step by step at a very slow rate until the shunt solenoid drops the lever H, thus arresting the oscillation of the fly-wheel Q. Since the latter is of considerable weight the to and fro motion can take place only slowly, and overfeeding should be almost impossible. The core of the shunt solenoid is provided with rings, *j j*, to prevent the air from passing too easily, and thus the motion of the core is steadied.

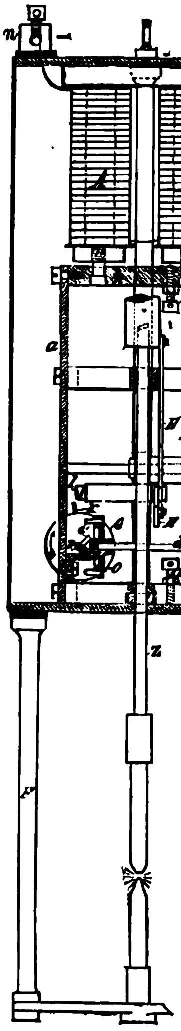


FIG. 1.

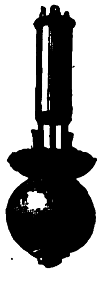

FIG. 4.

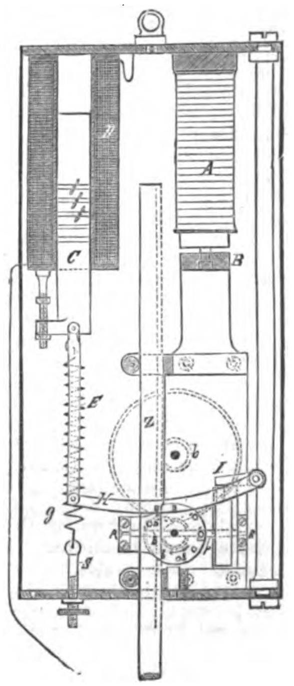

FIG. 2.

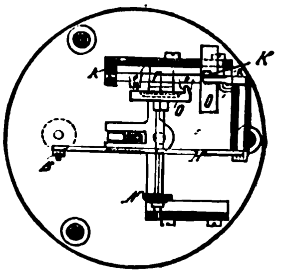

FIG. 3.

Dr. M. Krieg, of Magdeburg, has in the *Centralblatt für Elektrotechnik* published the results of a series of trials with these lamps, from which we abstract the following figures :—

Upper carbon (cored), 7 mm. ; lower carbon (solid), 6 mm.

Current in amperes.	Volts over terminals.	Length of arc mm.	Spherical candles.
4	48—49	2·5	198
3	48—50	2·0	119
2	47—50	1·8	76

Digitized by Google

Thus a mean luminous intensity of 76 candles could be obtained with an expenditure of 100 watts electrical energy, or about 1·3 watt per candle.

DOMESTIC ELECTRIC LIGHTING.*

BY W. H. PREECE, F.R.S., VICE-PRESIDENT OF THE SOCIETY.

Electric lighting, on some distributive plan like that of gas, is still an event of the future, in England. Other countries (notably the United States), Germany, Austria, Italy, Belgium, &c., are ahead of us; but in the electrical illumination of our homes—the traditional castle of the Englishman—we are in advance of all other countries. The number of private residences now lighted by electricity is very considerable. The way in which men of wealth have constituted themselves into amateur electricians is very characteristic of this country. There is something about electricity, in all its practical applications, that renders it captivating. Its marvels excite the imagination, its powers astonish the mind, its ready adaptability encourages invention, and its easy control favours its employment for many purposes where mechanical appliances would, in many cases, be more suitable. Hence, men of means and of leisure have made its study a hobby. There is no purpose to which wealth can be applied more beneficial or praiseworthy than that of aiding the thrashing out of problems whose successful results lead to the greater comfort and happiness of the many. Pure air in our lungs means health in our bodies and energy in our minds. The success of domestic electric lighting is a great sanitary question, and its solution has a much greater significance than mere commercial rewards. Municipal authorities expend fabulous sums in preventing the contamination of our water, but no local power has yet attempted to remove the poison from the air we necessarily breathe with our present mode of artificial illumination. Electric lighting does not do this, but it stops the supply of the vitiating gases.

Now, the progress of electric lighting in this country has been very seriously checked by the inordinate mania for speculation that characterised the year 1882, and the terrible losses that ensued therefrom; but there has been a quiet, steady progress made, that has not been checked by restrictive Acts of Parliament, and has not been deterred by misapplied capital. I want to chronicle what has been done, and how it has been done. The pioneers of domestic electric lighting in England have been Sir William Thomson, Sir William Armstrong, Mr. Coope, Mr. Sellon, and Mr. Charles Moseley. Sir William Thomson used a gas engine, and worked his lamps direct from the dynamo, not only lighting his house, but his class room and laboratory in the University of Glasgow; Sir William Armstrong obtained his power from a waterfall in his grounds; Mr. Coope used a steam engine; and Mr. Sellon and Mr. Moseley relied on secondary batteries, obtaining their power from a gas engine. Their good example has been very largely followed, and there are now a great many private houses in all parts of the country thoroughly and efficiently lighted. In fact, electric lighting is becoming a fashion, and the only fear for its ultimate general success is its falling into the hands of the inexperienced and ignorant—one chief cause of its check in the past. I have not known a single case of failure where the installation has been undertaken by experienced men. There have been many disappointments where

"Fools rush in where angels fear to tread."

Electric lighting means the utilisation for illuminating purposes of a certain amount of energy, which has to pass through various stages and forms, from its dormant condition in coal and water to its active condition in a lamp. I propose to discuss the question in each stage.

The Motor.—Steam, gas, and water have been used as agents for the production of power, but petroleum has not yet had a trial in England, and wind is too uncertain to be relied upon. Water is the most economical when it has not to be paid for, gas the most convenient, but steam is the most reliable. Electric lighting by incandescence absorbs much power. Power is the rate of doing work or of expending energy. Mechanical engineers measure this rate of doing work by referring to an arbitrary and erroneous standard called the horse-power; but electricians have introduced a new standard, more scientific and exact, called the watt. The watt is the work done in one second by an ampere flowing through an ohm, and having, therefore, an electric pressure of one volt. The number of amperes multiplied by the number of volts gives the number of watts. A watt is equal to ·7373 foot pound per second, and there are 746 watts in one horse-power. I am in hopes that the present horse-power will become a thing of the past, and that all engineers will measure power in watts, on the decimal system. A kilowatt is not such a euphonious name, but it is a truer and more scientific term than horse-power. An engine giving off 10 horse-power develops therefrom 7,460 watts. Now, an average glow lamp, well incandesced, gives one candle-power light for each three watts expended in it, and, therefore, a 20 candle-power lamp absorbs 60 watts, and a 10 candle-power lamp 30 watts. Hence, 10 horse-power, if all utilised in the lamps, will maintain 124 20 candle-power lamps, or 248 10 candle-power lamps in full incandescence. Thus, if we know the watts to be expended in the lamps, it is very easy to calculate the power required to maintain them alight. It is customary to allow eight 60 watt or sixteen 30 watt lamps per horse-power, so as to give a fair margin for loss in conversion and transmission.

A simple effective safe domestic steam motor has yet to be introduced. Hathorn, Davey and Co., of Leeds, exhibited at the Inventions Exhibition the best that has yet been made, but it has the disadvantage of requiring a large supply of water to condense the steam. It is a vacuum engine working at atmospheric pressure, and is, therefore, free from explosion. The various high-speed engines that have recently been introduced by Peter Brotherhood, Willans and Robinson, Fielding and Platt, Beauchamp Towers, &c., require higher technical skill than is usually to be found among the domestics of an ordinary household, and the difficulty of comprehending, examining, and repairing them stands in the way of their use. A simple single or double acting steam engine of small horse-power, that shall be economical in working and not liable to break down, easy of repair, that shall work with great regularity of speed, and be easily governed, and that does not require a skilled engineer to attend to it, is a great desideratum. The Society of Arts have under consideration a plan, so eminently successful in the agricultural world, and pursued for many years by the Royal Agricultural Society, of offering prizes for the best engines designed to fill the special purpose of providing power for electric lighting purposes. The points of merit that are considered to be of the greatest importance are—

a. Regulation of speed.
b. Power of automatically varying speed to suit variation of load.
c. Noiselessness.
d. Cheapness.

The competition is intended to embrace all classes of engines—steam, gas, petroleum, &c. The gas engine seems best adapted to supply this want. Gas is already in use in most establishments within reach of gas works, and it seems far more natural to utilise the energy stored up in gas to generate power, than to poison the atmosphere we breathe, deteriorate our valuables, and dirty our walls by burning it in air for illuminating purposes, especially as we get more light by doing so. Twenty-five cubic feet feet of gas will give us 1 horse-power, or eight 20 candle-power glow lamps, or 160 candle-power in all; but five 5ft. burners will give only 75 candles when burnt in air in ordinary burners. Gas engines are within the intelligence of butlers, gardeners, and coachmen; they are always ready for work; they attain their maximum efficiency at once; they can be stopped in a moment. They are not noiseless, though they are advertised to be so, and they are rather wayward. Some of them develop tempers of their own, and they occasionally cause angry expressions, but their efficiency is remarkable; and in spite of an oppressive monopoly nearly as bad as that of the telephone, they are rapidly coming into favour, and when the present patent expires, they will doubtless receive very great improvement, and much greater development.

In England, the opportunities of using water power are few and far between. Small powers are easily obtained, but from 10 to 15 horse-power requires a considerable quantity of water, or a higher fall than is usually attainable in any but hilly countries. The power of the tide, or that of a flowing river, is very small when utilised within the limits of ordinary people. The whole flow of the Thames through London Bridge would maintain only 800 lamps alight. In Scotland, however, the case is different. There several persons have utilised the water stored up in lakes. Sir John Fowler has lighted his highland home by using three turbines of 12 horse-power, which, night and day, work dynamos. A 5in. pipe from an artificial lake gives a head of 310ft. Many wonder why the wind is never used, but, apart from its uncertainty and unreliability, there is the fact that the power developed by the best windmills is, on the average, but very small. They are so unreliable that the proprietors of most windmills keep a steam-engine as a stand-by. The windmills so largely used in America and Holland for irrigation purposes exert but a fraction of a horse-power, and it requires a very wide expanse of sails to obtain, even in high winds, sufficient power to light a country house.

The Dynamo.—The relief which the practical world receives from the removal of the burden of a monopoly is well illustrated by the advances made in dynamos. The expiry of the Gramme patent was the signal for energy everywhere. Not only has the construction of the instrument been vastly improved mechanically, but its output has been trebled, and its price reduced to one-third; so that the dynamos of to-day are nine times better than they were during the existence of the patent. We are chiefly indebted to Elwell and Parker, of Wolverhampton, for leading the way. Hefner Alteneck first struck out a new path, which was taken up by Edison, and indeed has been well-nigh perfected by the high scientific attainments of Dr. J. Hopkinson. Science has converted a crude instrument into the most perfect converter of energy that exists. Commercial enterprise has brought it within the reach of all. I have for the past two years been converting 2 horse-power into electrical energy with an Elwell-Parker dynamo that cost £30.

The improvements that have been effected are due chiefly to the more intimate knowledge that experience and study have given us of the theory of the machine. Better shaped magnets, more intense fields, more accurate proportion of parts, better copper and better iron, improved ventilation, have trebled the energy given out by each pound of copper wound on the armature. The intensity of the field has been increased five times; machines are far less troublesome; faults have become less frequent; armatures do not burst up so often; sparking at the brushes is less evident; commutators do not cut so much; heating of the coils is a thing of the past; and the ill effects of self-induction are being eliminated. The forms of dynamos are being whittled down to two or three recognised shapes; but as long as the spirit of rivalry is stirred up by competition and emulation, so long shall we have some manufacturer who will make a change for the sake of a change, and who will advertise his wares as the best in the world. Suffice it to say, that for us users little remains to be desired in the quality and price of the dynamos. The output may be increased, and the speed may be reduced, but we cannot gild refined gold nor paint the lily.

The efficiency of a dynamo is the ratio of the energy given out in the external circuit to the energy supplied by the engine, and this in most

* Paper read at the Society of Arts, March 24 1886.

Digitized by Google

modern dynamos exceeds 80 per cent. The output of a dynamo is measured by the number of watts it delivers, and this becomes a very convenient measure and indication of its capacity. Dynamos are now indicated in kilowatts (or "units," as some call them), and when we are told that such and such a dynamo is a 12-unit or a 12-kilowatt dynamo, we know it can deliver 120 amperes at 100 volts, or 150 amperes at 80 volts, or 200 amperes at 60 volts, according to its requirements. This also enables us at once to determine the horse-power required to drive the dynamo. Twelve kilowatts means 16 horse-power, add one-fourth to allow for loss and waste, and we get 20 horse-power. Dynamos usually indicate the E.M.F. they work at when driven at a certain speed, and they have, or ought to have, the proper number of revolutions per minute engraved or painted upon them. If makers would only supply with their dynamos their characteristic diagrams we should have all the information the user wants. Dynamo sare classified into *shunt*, *series*, or *compound* wound, according to the work they have to do. The former are almost exclusively used for domestic purposes, for reasons which will presently appear. A well-constructed dynamo, kept clean and well lubricated, and never overworked, should last a lifetime without much attention, except to the brushes and commutator.

(To be continued.)

PHYSICAL SOCIETY.—March 13th.

Prof. BALFOUR STEWART, President, in the chair.

Prof. U. S. Pickering and A. C. Hayward were elected members of the Society. The following communications were read:—"On the Growth of Filiform Silver," by Dr. J. H. GLADSTONE. It has long been known that if a piece of metallic copper be placed in a solution of nitrate of silver, replacement of one metal by the other will take place, the silver being deposited in the crystalline form, sometimes having a resemblance to fern leaves, or as superposed hexagonal plates, or knobs. It was observed, however, as far back as 1872, by the late Mr. Tribe and the author, that if nitrate of silver were decomposed by suboxide of copper instead of the metal the silver presented itself in threads, which rarely, if ever, bifurcate, but frequently turn at sharp angles or twist in every direction. This was described in the British Association report for 1872, and it was observed that the same forms occurred in native silver. More recent observations have shown that the particular character and rapidity of formation of these threads depends very much upon the strength of the solution, and the condition of the suboxide. Hydrated suboxide will scarcely decompose a two per cent. solution, even after standing. The threads, which bend at a sharp angle, usually do so at 60 deg. or 120 deg.; other threads, however, are symmetrically curved; but, especially in strong solutions, they are given to twisting about in every direction, and generally terminate in irregular knobs of silver. As a rule a thread continues to grow of the same thickness as it commenced, but it sometimes enlarges for a while into a flat plane, or becomes encrusted for some distance with small crystals of silver. When the solution is very nearly exhausted of silver, fine arborescent forms appear; but with the suboxide there are never produced the fern-leaved forms, or hexagonal plates, or the other distinctly crystalline structures which characterise the growth from metallic copper. During the reaction the suboxide is changed into black protoxide and metallic copper, which dissolves; and the change will take place as well with the acetate and sulphate as the nitrate. If a mixture of suboxide and metallic copper be employed, not only do the distinctly crystalline and the filiform forms make their appearance, but strange intermediate forms come into existence.

"Apparatus for Measuring the Electrical Resistance of Liquids." By Prof. REINOLD. The apparatus consists of two bottles connected by a horizontal tube. The whole is filled with the liquid to be examined and immersed in water, by which means and by thermometers inserted in each bottle the temperature may be regulated and accurately ascertained. The electrodes are platinum plates, one dipping into each bottle. Two fine tubes terminate near the ends of the connecting tube, and electrodes are fitted into them at some distance from the ends; by connecting these to a quadrant electrometer or a condenser and galvanometer, the difference of potential between the ends of the tube can be compared with that at the ends of a known resistance in the same circuit.

"On Chromatic Photometry." By Capt. ABNEY and Lieut.-Col. R. FESTING (this paper had been previously communicated to the Royal Society). A series of experiments had been made by the authors to determine the comparative luminous effect of different parts of the spectrum. A monochromatic light from any part of the spectrum of the electric arc was obtained by a method devised by Captain Abney, and previously described by him to the Society [Physical Society, June 27, 1885]. The photometric effect at different parts of the spectrum was compared with that due to a candle at different distances by Rumford's photometer. In using this it was found best to place the candle in a given position, and obtain a balance by moving the slide upon which the spectrum was formed, and through a slit, in which part of the light was allowed to pass, rapidly to and fro. For each portion of the candle there are thus two corresponding positions of the slit. From the results of these observations a curve may be drawn showing the luminosity at different points. From the method by which it is obtained it is evident that the curve of one observer is not directly comparable with that of another, since a deficiency of perception in any part of the spectrum would affect the light of the candle as well as that examined. Since, however, the curves obtained by a great number of persons coincide very closely with those obtained by the authors, they have felt justified in adopting them as the normal curves. In the case of the electric arc the normal curve attains a maximum rather nearer the red end of the spectrum than the blue. Assuming the normal curve, any other curve may be compared with it by increasing or decreasing its ordinates so that no part of it shall lie without the normal curve; in curves thus obtained, several of which were shown, deficiency in colour perception is often very clearly marked. By the use of two or more slits in the movable slide experiments were made upon mixtures of colours, and it was found in all cases that the luminous effects of a mixture of colours was the sum of the luminous effects of its components. It was also found that the colour of the comparison, and the quantity of light admitted to form the spectrum, were without effect upon the form of the curve. Light from the sun, and from an incandescent lamp, were similarly examined, though it should be observed that the result for sunlight differs notably from that given by Maxwell. An examination has also been made of light after passing through a turbid medium, and an expression of Lord Rayleigh's

$$I' = I e^{-x\lambda^{-4}}$$

where I is the original radiation, I′ that after passing through the medium, λ the wave length of the light, and x a constant depending upon the medium, has been closely verified.

COMPANIES' MEETINGS.

German Union Telegraph and Trust Company (Limited).

The fifteenth ordinary general meeting of the shareholders of this company was held at the offices, Winchester House, 50, Old Broad-street, on the 22nd inst., Sir James Anderson in the chair.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting.

The report of the Directors for the year ended December 31st last, stated during that period the total receipts amounted to £10,930, which, with the balance brought forward, made a total of £11,036. The expenses for the same period amounted to £823, of which £750 was provided by the German Union Company of Berlin. The renewal fund and reserve fund of the Berlin Company now amounted to £58,000. The capital was £330,000. The cables were in good working order. The International Telegraph Conference, held in Berlin last year, had introduced reforms of great importance for European traffic. The Agreement for the reduction of tariff between Great Britain and Austria and the countries beyond, which the Berlin Company accepted, had led to a satisfactory development of the traffic, and it was hoped that their receipts, by a further increase in this traffic, would not suffer any loss.

The CHAIRMAN: Before moving the adoption of the report, I shall, as usual, make a few observations on it. You will notice that it is very short and very concise, and explains, as far as the working of the year goes, all that can or need be said. There is a diminution of the revenue, arising from the fact of the competition of the Atlantic companies and the reduction in their tariffs, compensated, however, to some extent, by the increase of traffic between Great Britain and Germany. That, perhaps, is the main point in the report. Last year I notice in looking over the the report of the meeting I referred to the Telegraph Convention then pending, and I held out hopes that we should be able to get a resolution passed, limiting the use of code language. At the Conference that matter came up on two occasions at the Tariff Committee, and on both occasions a motion was carried by a considerable majority that we should have an authorised code, using the eight languages and the dictionaries of the eight languages; but at the general conference meeting held to confirm or re-discuss the matter, the motion was lost, and I found to my regret that we were divided among ourselves—I mean the managers of the different telegraph companies in England were not unanimous by any means as to the adoption of an authorised code or the adoption of the dictionaries of the language. The Post Office and India were against it, and others whom I need not name. The main ground of their objections was that it would irritate our customers, the merchants. My own idea was and is that by giving the merchants a few years to consider and eliminate all the words which did not properly belong to the language, they would soon fall into a code that we could understand, and as to which there would be no further objection hereafter. However, that motion was lost, and we are now fixed for five years of taking things as they are; and so far as my reflection extends, it appears to me that we are going in the direction of reducing tariffs, though gradually, I hope, until we attain a point below which even the public cannot expect us to go. I have long foreseen and said this. As to code language, I do not yet see the limit of condensation of telegrams, and of the use of combinations of words in such form that no general run of operators can be expected to challenge. I am in hopes that there is a minimum below which merchants cannot or will not care to condense; but in these two directions we are inevitably going, and the merchants have five years during which to condense the length of the telegrams and to expand the meaning of the words which they can combine, making them look like regular words of the eight languages. I do not know that one need regret it, but it will be a struggle with all the telegraph companies until they have arrived at that point. Happily, I think, the use of telegraphy is growing, and must grow, and therein lies our hope, together with the extended "life" of the cables. So far as the German Union Company is concerned we are fairly well off. We have, as you observe, a growing reserve, and all those who are associated with the management of telegraph cables look at that as their sheet anchor—to have a large reserve suitable either for

Digitized by Google

renewals or repairs, regarding it as indispensable in submarine cables, which are under the water, and subject to wear and tear such as we are not fully cognisant of, and have no means of informing ourselves of except by experience. I am happy to say that within the last few weeks we repaired a cable of the Eastern Company in the Mediterranean 18 years old, and the captain reported that it was in excellent condition except just where it had broken; but to have broken after 18 years, and to be no worse after that period is satisfactory.

Mr. WM. FORD: What was the depth?

The CHAIRMAN: It was forty-five fathoms; but that it should be good there is more wonderful than it would be if it had been in deeper water. The advantage of the position of the German Union cables is that they are in shallow water, so that no time need be contemplated in my opinion for the absolute renewal of the whole length. We may have repairs and extensive repairs, but I should say that this is as safe a property as can be devised as regards submarine cables. With these remarks, I move the following resolution:—"That the report and accounts for the year ended 31st December, 1885, submitted to this meeting be, and they are hereby received and adopted; and that a dividend of 4s. 3d. per share be declared payable this day free of income-tax, making, with the previous distribution of 5s. 9d., a total dividend for the year of 10s., or at the rate of £5 per cent. per annum."

Mr. H. G. ERICHSEN seconded the resolution.

Mr. GRIFFITH said he feared they must agree with the Chairman as to the probability of the merchants trying to cut the rates, and so diminish the Company's income to a certain extent. He was, however, glad that the Chairman was able to hold out the hope to them that from the development of traffic on the Continent they might to some extent recoup themselves. It struck him that if telegraphy was developing itself so much on the European Continent there might be room, possibly, for them to extend their operations. They were not merely the German Union Telegraph, but also a Trust Company. They knew how greatly the trust companies in England had succeeded, and he wished to suggest that if anything could be done in the same direction as regarded the European Continent, it would be a benefit to the Company. At present all their property was in one Company. He, however, hardly knew what their property was; and he asked the Chairman to tell them what were the cables of the Berlin Company, and the probability of extending telegraphy on the Continent; and also whether there was a probability of converting the Company into a Trust Company for the purposes of the Continent.

The CHAIRMAN: I will give you a map showing you where the lines are; but to reply to the questions I must go back to the history of the Company. This is a German Company. Its head-quarters are at Berlin, and we are merely agents of the Berlin Company. Prince Bismarck absolutely declined to let us make it an English Company, though all the capital was held here—that is, almost all, for the Directors held their qualification and a little more in Germany. The capital, however, was English capital, and that came to be so much recognised that an effort was made to make it an English Company. We were invited to represent this, but we failed, and we remain simply trust agents for the Berlin Company.

Mr. GRIFFITH: There is no possibility of going to law with the redoubtable Bismarck?

The CHAIRMAN: Oh, no; and besides, there are no Continental cables except Government cables. We have the right by our position to all undirected German traffic, which is of substantial value to this Company. I do not know that I need enlarge on the question, but there is nothing to take into the Trust. We are simply agents for this Berlin Company, and there are no cables on the Continent except Government cables, nor are there likely to be any.

Mr. FORD: There are no companies you could take in?

The CHAIRMAN: No, and none likely to be. Everything is in the hands of the Governments. We have not overlooked the point raised by Mr. Griffith. We have a cable now from the Anglo-American station at Valencia to Emden, and a cable across from Lowestoft to Emden. Those are all the cables we have, or are likely to have. He then put the motion, and it was carried unanimously. Continuing, he proposed the re-election of the retiring Director, Mr. John Denison Pender.

Count OSCAR VON REICHENBACH seconded the resolution, which was carried unanimously.

Mr. PENDER having briefly acknowledged his re-election,

Mr. FULLER proposed, and Mr. KENNETH ANDERSON seconded, the re-election of the auditor, Mr. Henry Dever, F.C.A., which was unanimously agreed to.

Mr. FORD then proposed a vote of thanks to the Chairman for presiding, and to that gentleman and the Directors for their conduct of the Company's affairs. It was some satisfaction to hear that, in these days of change, they would have five years' uninterrupted enjoyment of such privileges as belonged to them at the present time. Five years was almost eternity in these days, but he hoped at the expiration of that period that the days of Democracy would not have come upon them, and that there would still be some rights and privileges for property to enjoy.

Mr. GRIFFITH, in seconding the motion, referred to the great ability of the Chairman, and to the urbanity and readiness with which he gave explanations and information which might be asked for.

Mr. FORD put the resolution, which was carried unanimously.

The CHAIRMAN: I am very much obliged to you on behalf of my colleagues and myself. We do all we can to help our colleagues in Berlin, and we did what we could while we were there last year. We are very much indebted to our Managing Director there, Dr. Lasard, for the way in which he saw all the changes and reductions on the Continent, there being no reduction for us. Germany did all she could to get the companies to reduce their rates, but I do not find that she has reduced them much for herself [laughter].

The meeting then separated.

The Direct Spanish Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of this Company was held at the Company's offices, Leadenhall-buildings, Leadenhall-street, E.C., on Tuesday, 23rd inst., under the presidency of Sir James Anderson.

The MANAGER (Mr. Ch. Gerhardi) read the notice convening the meeting and the minutes of the last general meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Before moving the adoption of the report I shall make a few observations. At the last meeting I find I dealt with what we had done at the Telegraph Conference, and I referred a good deal to our failure to get the line through Spain from Bilbao to Carthagena, and I referred also to the fact that we had failed in obtaining a good direct wire from Madrid to Bilbao. This has been the object of this Company for a great number of years, and I am happy to say that it has met with the approval of the Cabinet of Spain for the first time, and thanks to the good offices and friendly disposition of our ambassadors, Sir Robert Morier and Sir Clare Ford, the Cabinet have put the matter in train, and we are now likely to get a good wire established from Madrid to Bilbao. We think that this will be of considerable advantage to us in improving the traffic, for, after all, the speed has a great deal to do with it. Next we are endeavouring to obtain an office in the Bourse at Barcelona. Our manager, Mr. Gerhardi, will go over there in a day or two to push the matter. If we had an office in the Bourse, we have many reasons for supposing that the traffic would be more reliable and would increase. Hitherto there has been a strange divulging of messages in Spain that we have been unable to trace, and unable to control, notwithstanding all sorts of efforts that we have made. I may say that the divulgence of those Bourse messages has induced the brokers to send fewer telegrams than they might otherwise have done, and we hope by getting that office we shall get more traffic. In these times of great depression, it is very gratifying to see from *The Times* of the 15th inst. that the whole of the exports of Spain in 1885 were 40 millions sterling, a figure which some years ago was assumed as the total of Spanish exports and imports. The fact is that the Spanish trade appears to be increasing. I have read somewhere that someone has come over here, or is coming over, to endeavour to bring about a *modus vivendi* with the British Government by which we shall enjoy the favoured nation clause commercially with Spain in the same way as other nations are now enjoying it. You all know that for a long time Spain has refused to give Great Britain the favoured nation clause on account of our alcoholic tariff, but I believe we have always been ready to alter that as soon as she should show a disposition to give us the same terms as she gives to Germany, France, and other countries. These are the two hopeful signs of our future. Then I referred at the last meeting to the postponement of examining the old cable between England and Bilbao. The Eastern Company were not in a position to lend us one of their smallest priced ships for that purpose, because they had unfortunately lost a ship. Now, however, the Eastern Company has two ships coming home next month, and they will be coming home with their tanks empty, and I have proposed that these two ships should go into the Bay of Biscay, and take an independent engineer, a member of the firm of Clarke, Ford, and Taylor, who shall superintend the picking up of the cable, and examine it so as to see how far it is worth raising and repairing—whether, in fact, it is worth retaining as an asset, or whether it is cheaper for us to recommend to you to condemn it and reduce our capital. The other ship will come on to Falmouth, and will be there joined by one of the assistants of Clarke, Forde, and Taylor, and they will examine the part in the Channel, and bring home the cable, and we shall see with our own eyes whether it ought to be retained as an asset, or whether the capital should be reduced. These things are being done, and I do not know anything more that could be done. In fact I am sure nothing could. We still have to regret the reduction of the length of telegrams. We do not appear to have got to the bottom which merchants are determined to arrive at in the reduction of the length of telegrams, or in the combination of certain words to mean a great deal more than we ever contemplated when codes were introduced. But we failed at the last Convention to get that protected or altered, for even though on two occasions it was passed by the tariff committee, it was rejected by the full conference, and as I have said on a recent occasion the merchants have now five years to run during which they may condense their telegrams as much as they choose, and make them as cheap as possible for themselves. But I am in hopes that with the reduced tariff that we are now coming to, and with the condensation already arrived at, we are not far off the bottom of these things which are pulling against us. I am happy to say there is a small gleam of comfort in the fact that our traffic has improved during the last quarter. We have £500 to the good as compared with the same period last year, and I do not see any reason at all why the Spanish traffic should not be double what it is now. At present the traffic is ridiculous for a country like Spain, and I do not think we are anything near its full development. I am not a pessimist, and therefore I look hopefully to the future. He concluded by formally moving the adoption of the report and accounts.

Mr. EDMUND ETLINGER seconded the motion.

A SHAREHOLDER asked what would be the cost of a new cable.

The CHAIRMAN: We paid £60,000 for the last one, and I do not suppose we could get a new one for anything less, and I do not think it would be wise to contemplate laying a new cable unless we saw our way clearly to make it pay. The new cable is represented by debentures and the old cable by the capital. If you lose the latter your assets are gone. It may be that we might find half of it worth repairing, and that a small amount would make it intact.

Mr. HUGHES wished to know whether any payment to the preference shareholders depended on the state of the old cable.

The CHAIRMAN replied that in some measure it must. They had no reserve to speak of now and their assets were not properly protected with-

Digitized by Google

out a reserve. They could not really decide what should be done until it was settled whether they were to reduce the capital or not, which could not be carried into effect without convening a meeting of the shareholders.

Mr. COCHRANE animadverted on the fact that the Company was asked to pay income-tax when it was earning nothing. He suggested whether a committee might not be formed for the purpose of transfering the Company to the Eastern Company, and expressed his dissatisfaction with the constitution of the Board, two of the directors being also directors of the Eastern Company.

The CHAIRMAN pointed out that the Eastern Company would not buy it, for the Direct Spanish had not much to sell. In the course of the next month they would know something more about it, and it would be the duty of the Directors to call a meeting to put the whole state of the affairs before them, and consider the question of the reduction of capital. The assets of the Company never represented the capital by a long way. If the shareholders brought about any reduction in the capital he would personally only be too glad.

A SHAREHOLDER asked what would be the cost of repairing the old cable.

The CHAIRMAN said that experienced engineers were going out practically at cost price, quite independent of this Company and the Eastern Company, and it was for them to say how long the ship would continue working and picking up the cable. But if after picking 40, 50, or 100 miles, or any part of it, they came to the conclusion that it was simply whipping a dead horse to proceed with the work, they would at once stop and come home, and tell the Directors the state of affairs.

The motion was then carried.

The retiring Directors, Sir James Anderson and Mr. John Denison Pender, were afterwards re-elected, as was also the auditor, Mr. Herbert R. Duke, and a vote of thanks having been passed to the chairman the proceedings terminated.

Electrical Power Storage Company (Limited).

The adjourned fourth ordinary general meeting of the shareholders in this Company was held at the Cannon-street Hotel on the 25th inst., Sir Daniel Cooper, Bart., in the chair.

The SECRETARY (Mr. Holland Dell) read the notice convening the meeting, and the Directors' report was taken as read.

The CHAIRMAN said: Gentlemen, I consider the most convenient method of transacting the business before us will be to deal with the years 1884-1885; at the same time the discussion must include both years, and my remarks will therefore cover the same period. At the conclusion of the adjourned meeting the fifth ordinary general meeting will be held. The report deals fully with all the points of interest to the shareholders, and I now propose to make some observations upon it and the statement of accounts. You will have gathered from the report that the business of the Company has rapidly increased, a marked improvement having taken place during the latter half of 1885, and the prospects for the current year are extremely encouraging. In accordance with the Articles of Association the accounts of 1884 have been open for inspection at the offices of the Company, and the balances therefrom have been carried forward to the accounts of 1885. You are aware that a heavy loss was made in 1884, but the result of a complete change of management is that in 1885 we have made a profit upon manufacture, and are now also receiving cash remittances from the realisation of our patent interests abroad. We propose to spread the suspense account of 1884—£9,848. 19s. 10d. over the next five years, as we consider this amount was not fairly attributable to 1884, but to 1883 as well. The year 1885 shows a gross manufacturing profit of £10,902. 17s. 10d. I think you will agree with me that these figures are most satisfactory considering the adverse circumstances we have had to struggle against. We undertook to greatly reduce the expenditure; we have done so, and have at the same time secured thorough efficiency. The net result is that the profit and loss account for the year 1885 exhibits a profit of £2,200. 9s. 2d. The past two years have been a period of great anxiety to the Directors, and we have all given unremitting attention to the affairs of the Company. I would point out that we have not taken any fees, but we intend, with your approval, to take them in future. You see from the balance-sheet that when the shareholders did not come forward sufficiently to support the Company, the Directors provided the cash with which the present satisfactory position has been attained. The Millwall works are large, and amply sufficient for an increased output, and a slight strengthening of the staff, as at present organised, would suffice for this purpose. The manner in which the electrical and engineering work entrusted to the Company has been carried out by our engineer (Mr. Drake), the works manager, and the staff, has met with general approval, and a reputation for thorough workmanship has been acquired which has placed the Company in the first rank of electrical contractors. In proof of this I would mention two of the latest installations carried out in London, viz., the Bank of New South Wales and Lloyd's, as examples of the Company's work, which are readily accessible to those desirous of being convinced as to the efficiency of its installation work. A third installation, that for 1,500 lights at the Prudential Asssurance Company, is not yet completed, but will, when finished, I do not hesitate to say, stand pre-eminent for magitude and quality among the electric light installations of this or any other country. The Company is now extending the field of its operations, as, for example, the lighting of the Folkestone Exhibition, the contract for which has been given to us on satisfactory terms. As a frequent visitor and well-wisher to the town of Folkestone, I am very desirous for the success of this Exhibition, and I have no doubt that our staff will make a perfect success of the electric lighting there. We have also contracted to furnish a large number of lights, about 1,000, for the forthcoming Colonial Exhibition, in which I, of course, take a deep interest. The batteries have for some time past given every satisfaction to purchasers, and have been adopted by all the large electrical companies and firms, and by many private gentlemen for their residences. Among these may be mentioned Sir William Thomson, Sir W. Armstrong, Mr. Harben, Mr. Littleton, Mr. Fred. Green, Sir David Salomons, Lord Thurlow, and many others. The Directors have personally brought to bear what interest they possess in getting orders for the Company, and several installations have already been the result, and they ask the shareholders to assist in the same way with their friends in the lighting of private houses, banks and companies, where their influence may be of much service. In temporary lighting for balls, evening parties, &c., the company is doing good business. Among them the lighting of Marlborough House for H.R.H. the Prince of Wales, and Grosvenor House and Eaton Hall for His Grace the Duke of Westminster, may be specially mentioned. In the propulsion of boats and tramcars large progress has been made during the past year, and we may expect the progress to continue. On the Continent electrical tramcars are used, as at Berlin and Antwerp, and are having more attention than even in this country, and as regards the propulsion of boats we look for more orders for this class of work from the successful running of the Duke of Bedford's electric launch. A considerable extension of train lighting can also be expected during the current year. The London, Brighton and South Coast and the South Eastern Railways are determined to meet the wishes of the public for the electric lighting of railway carriages, and other companies have the matter under consideration. In regard to the long-continued negotiations in the United States, to which I alluded at previous meetings, it is with much satisfaction I have to announce that they have been brought to a successful issue. It gave the Directors much pleasure to welcome to England the American gentlemen who, with their electrical staff, have just returned to their own country, after a most thorough study of the methods of manufacture of batteries at Millwall and the installations erected by this Company. They are the gentlemen to whom reference is made in the report as having recently associated themselves with the New York Electrical Accumulator Company, in which we have a large interest as shareholders, and who by energy and skill in management have already achieved a brilliant success in America in another direction. Mr. Theo. N. Vail, so well known in the States in connection with the American Bell Telephone Company, has accepted the post of president of the New York Electrical Accumulator Company. The outlay in the United States has been necessarily large, but we believe that we shall be now amply repaid. Regarding the foreign business I have nothing to add to what is stated in the report. We are pushing the business and selling the batteries direct throughout the Continent. The suit in Germany relates to a lien alleged to exist against the Faure German patent before it was transferred to this Company, and this claim, therefore, affects the payment of the German royalties. I cannot avoid referring to the injury inflicted upon our business by the Electric Lighting Act of 1882, and I rejoice to see that there is hope of its amendment during the present Session of Parliament; but we must not relax our efforts for an alteration of some of its most obnoxious clauses. The Bill brought in by Lord Rayleigh in the House of Lords deserves our warmest support. We have to regret the death of our colleague, Mr. William Ladd, which occurred last autumn. I think I have now touched upon most of the points in the report, but we shall be happy to give any further information that may be desired. I may add, in conclusion, that we are really now in the meeting for 1884, but if we merely asked you to approve of this report and statement of accounts, and then pass on to 1885 matters, it would stop any discussion on those relating to 1884. We think it best to keep the whole open for discussion, and when you have finished we will ask you to pass the 1884 accounts, and then we shall have to resolve ourselves into the meeting for 1885, and ask you to do what is necessary there. The first resolution I have to put is "That the accounts of 1884 now submitted to the meeting be received and adopted."

The VICE CHAIRMAN (Mr. John Scudamore Sellon): Gentlemen, I beg to second the resolution which has been put before you by the Chairman, and in doing so it is, of course, a great pleasure to be able to say that my long since recorded conviction seems now about to be justified by the event—namely, that to this Company, if wisely directed, honestly conducted, and efficiently managed, would be assigned the foremost position of all the important undertakings connected with the electric industry. When domestic lighting was first initiated an apparently insuperable difficulty supervened, namely, the non-existence of any means by which a continuous supply of light could be insured unless the motive and generating power were in motion—that is to say, unless the engine and the dynamo were working continuously; and even under such difficult and inconvenient conditions, the disadvantages of an unsteady and flickering light, of destruction of lamps, and of accidental breakdowns, were unavoidable. It was this intolerable state of things that made the introduction of storage batteries absolutely necessary, and we all know how, in spite of enormous difficulties, it has made its way; how the scientific and practical electricians of the present time recognise that no isolated installation is complete or perfect without it. This being so, let us consider our present position. Confidence is established in our manufactures, and we all know that progress is making rapid strides in the electrical industry. The absolute necessity of the storage system is, as I have said, generally recognised. Experience has been gained fortunately during a period when but a limited amount of work could in any case be possible, and you have, as your property, intact, patents which command the whole field in this branch of industrial work, to which I think no limit can be assigned. You also have a competent managing director, who devotes his time and energy to your service. Under him you have an efficient and trustworthy staff, and I venture also to suggest that you have a Board who spare no efforts to advance and secure your interests. In these circumstances it is scarcely difficult to forecast what the future of this Company should be. If you have such conditions as good manage-

Digitized by Google

ment, and the control of what I assert to be one of the most important factors in connection with the rising industry of the age, I think that, however high our hopes may have been raised, they will in the end be fully justified.

A SHAREHOLDER said he thought they ought to have the report of the auditors before they were asked to pass the accounts.

The MANAGING DIRECTOR (Mr. John Irving Courtenay) having read the report of the auditors, Messrs. Deloitte, Dever, and Co.,

The CHAIRMAN said they had thought it best to go on with the meeting rather than delay it a fortnight or three weeks to go over the accounts again in order to discover the item of £6. 8s. which they had not been able to trace. At their first meeting, however, that matter would be reported upon to the shareholders.

The MANAGING DIRECTOR added that the balance of £6. 8s. was discovered at the last moment. If they had not summoned the meeting they would not have held it until it had been found.

The CHAIRMAN then put the resolution, which was carried unanimously. Continuing, he said: We now resolve ourselves into the meeting for 1885, and it is a source of great pleasure to me to get rid of our previous history up to the end of 1884, but anything more unpleasant or more harassing I cannot understand. I hope in the future, if we do not have very rosy accounts, we shall have very satisfactory ones. I hope we shall show profitable accounts. I now move the adoption of the report and accounts for 1885.

The VICE-CHAIRMAN: I beg to second the adoption of the accounts for 1885.

The CHAIRMAN put the motion, which was carried. Continuing, he said: The next matter is the re-election of retiring Directors. I beg to propose the re-election of the vice-chairman (Mr. J. S. Sellon), and of Mr. J. Irving Courtenay, the managing director. In regard to Mr. Sellon I need hardly say his knowledge and experience are of great importance to us. Mr. Courtenay is now our managing director. It is not usual for a managing director to be put up for re-election, and it may be advisable at a future meeting to alter the Articles in this respect. Mr. Courtenay has resigned the directorship of another electrical company so as to give more time to the business of this Company, and we have been fortunate in securing his services for the term of three years.

Mr. NOEL (a shareholder) seconded the motion, and it was carried unanimously.

Mr. COURTENAY: I have to thank you, gentlemen, for my re-election. The latest and by no means least interesting of our testimonials has been handed to me, and as it is from a man who is so well known all over the world, and has not yet been published, I think we cannot do better than conclude the business by reading it to you. It is a testimonial as to our batteries by Sir William Thomson.

Mr. Courtenay then read the communication, which appears in another column of our present issue.

Mr. CAWSTON said that the balance from the trading account was £10,900, and that the net profit on the trading was only £2,200. Considering their expenses at Millwall, he thought the expenses at the head office of £2,500 were very large. A sum of £1,500 was also paid for miscellaneous expenses. It seemed to him that the expenses were altogether out of proportion to the profits. While, too, they had derived only £131 from royalties, they had spent £1,000 on law expenses.

The MANAGING DIRECTOR, in reply, said that Mr. Cawston's remarks were made out of order, the report and accounts having been passed by the meeting, but the Directors were glad to give the information. Mr. Cawston thought the expenses at the head offices were high, but they were a great deal lower than they had ever been before; and he had no hesitation in saying that if they went through the items in the office it would be seen that the work was done more economically than anywhere else in London. Their rent was very high, but they had managed to reduce that. If, however, they took the payments of the various officers, including the engineer and himself, and made them up, they would find that they were lower than almost any other electrical company. The engineer's salary went against the head office. Coming to the item of law expenses, patent fees, and charges, they had had a heavy lawsuit—two, in fact, one in connection with their late works manager. Then there had been the Elwell-Parker suit, which had been satisfactorily settled, and that firm now paid them royalties. Nothing, however, on that head was included in the accounts, which went up to the close of last year, and the royalties did not commence to run until about the beginning of the present year. As regarded the other law charges, if they did not think fit to defend their patents, either in this country or abroad, they might as well retire from business, because persons would not pay the price of a patented article if the owners of the patent allowed others to manufacture it without taking proceedings against them. The Directors, however, intended to proceed against those who infringed the Company's patents. The accounts were not yet credited with any royalty either from the firm of Elwell-Parker or any one in this country. The German royalty, too, was "hung up" on account of a dispute regarding the title of one of the patents; and the Court stated that the royalty could not be paid to the Company before that matter was settled. As regarded the litigation in the United States, that was now satisfactorily settled; and the American interest they had now in New York was a most valuable property. They had had a heavy expenditure in connection with these matters, but it would all come back to them, and indeed was now coming back to them. He knew it was dangerous to prophesy, but he would be very much disappointed if by the end of this year they did not receive a great deal more money from abroad than they paid out, that was to say, that the outlay for this next year would be very much less than the cash they would receive. They could not, however, expect anything if they did not defend their property, and however much they would all prefer peace, if there was a direct attempt to rob them by pirating their patents they must take action and defend their property. They had received in the past month a substantial sum from America, but it was not to their interest that he should state publicly how many shares they held in the American Company.

The CHAIRMAN said it ought to remembered, as regarded the expenses, that theirs was a young Company and a young business; and until they got to a certain point the expenses were always entirely out of proportion to the business done. They really only began business towards the commencement of last year. It was not until they had made the existing arrangements that they began to do profitable work, and the profit shown had been all made in about six months. Mr. Drake and Mr. Gorham had done what no other men in their department had done. They had worked for the Company day and night to bring the Company's accumulator into a state of perfection, and it had been brought to a state of perfection which they had scarcely ever expected it to attain. The Directors did all they could to attract business, and they were constantly at the office. They never spared themselves, and he could say the same of the officers. They had worked the thing up from a wretched into an excellent state. A good deal might be said respecting the litigation on the Continent, but they did not think it would be wise to give a foil to their opponents. When, however, they got to the end of the matter they would be able to lay before the shareholders the result. It had been the same with the American business. That seemed in a hopeless position, but all at once, by their persevering, it took a turn, and he hoped they would get something like what they originally expected. To state everything fully, however, would be prejudicial to the interests of the Company; but when matters were closed, whether they failed or succeeded, the result would be made known to the shareholders.

A resolution having been passed re-electing the auditors, a unanimous vote of thanks was accorded to Mr. Drake, Mr. Gorham, and the staff.

On the motion of Mr. CAWSTON, seconded by Mr. NOEL, a hearty vote thanks was passed to the Chairman and Directors.

The CHAIRMAN, in reply, said: On behalf of my colleagues and myself I promise that you shall have the very best of our time. It is much more cheering now, especially when we meet with approval in what we have done. I assure you that you can have no idea of the amount of time and anxiety it has given the Board of Directors to get the Company out of the false position it was in, but adversity sometimes leads to prosperity; and I think the lesson that we have had will, now that we see our way to good business, lead to prosperity. I will promise you that we will give our very best attention, and all the time we can possibly spare, to work the Company up to a state of real prosperity, and I hope we shall give satisfaction. Without boasting, we are in a position now, with the assistance of the officials whom you have been kind enough to thank, to make an installation better than any other Company in existence. Not but that there are very clever men, and men who, according to their systems and ideas, do the work extremely well; but what you require in private houses, banks, and large installations is to have a perfectly steady light, like that to which Sir William Thomson refers. Sir William Thomson, too, is not the only man who found this out. Sir William Armstrong would not think of going to any other light. Mr. Preece, of the Post Office, is also satisfied. He has it in his house. And there are several of the other leading electricians who you may say only a few months ago doubted whether we had got an accumulator, and then they thought we might have something that was rather better than any other going; but still they had no confidence in it. Now, however, every installation we make proves to these men that we have not only got a really reliable accumulator, but one that gives a light adapted to the eye, and to pictures, a light such as has never before been in existence. I am quite certain that month by month we shall attain a solid and satisfactory position, and it is the encouragement we now get from you as shareholders, and the encouragement we are getting from these leading men and the public, that cheers us on. I hope that, although the work may occupy much of our time, it will not, at all events, give us the anxiety we have had in the past, with shortness of money and everything about us unreliable and unsatisfactory. I hope my observations now will also give you some encouragement to stand by us and help yourselves and help the Company in getting into this leading position. Our engineers wish—and we encourage them—to do all the work in as perfect a manner as possible, and not to go in for a large quantity of work and do it in an indifferent manner, which would only cause a certain amount of want of confidence in us. The work we do we try to do as perfectly as possible, so that when an installation is started it goes straight, and there is no patching afterwards required. I think if we follow that course we shall work up this Company into a most satisfactory condition. If the Act of 1882 is altered—and it must be, for it is unworkable—we hope to be in a position to increase the business of the Company very largely, and we can do that without much increasing the expenses of the head office or at Millwall. In fact, the only increased expense we should have would arise from a slight strengthening of the staff. I beg to thank you for your kind votes of thanks to my colleagues and myself, and to Mr. Drake, Mr. Gorham and the staff.

The proceedings then terminated.

The Swan United Electric Light Company (Limited).

The adjourned third ordinary general meeting of this Company was held on the 23rd inst., at the Cannon-street Hotel, Mr. James Staats Forbes in the chair.

Major S. FLOOD PAGE (the secretary) having read the notice convening the meeting, the report of the Directors and the statement of accounts were taken as read.

The CHAIRMAN: I will make a very few observations upon them. I do not know whether any honourable proprietors were present at the meeting of

Digitized by Google

the United Company, with which we are so nearly allied—the Edison and Swan Company, because what I have got to say to-day as to the results of the Swan Company, as distinguished from the Edison and Swan Company, bears a good deal of analogy to what took place at that meeting. It is very important to the Swan Company, because, as you know, as reference to the balance-sheet will show you, you are the principal shareholders in the United Company, the difference between the two things being that you have a foreign business to carry on and develop over and above the business which is to be carried on and developed in Britain. Well, now, these things are very much alike. What took place at the Edison and Swan meeting was this: We showed that both the Edison Company and the Swan Company in their initiation had made great mistakes, had paid too much for their patents, they had entered on business of which they were not masters upon terms which were very onerous, and the first duty of the united Board had been to thoroughly "bottom" the affair, make up their minds what they ought to do and what they ought not to do, and to carry on the business in future upon a sound basis. We were able to come forward at the end of the first year of the "new light," so to speak, and show the proprietors that following a particular policy, instead of landing us in a very heavy loss—£28,000, I think it was the preceding year, under the old state of things—we converted that loss into a profit of £12,000, and you remember that those accounts for the year's working showed a profit of £12,000. We did not distribute that; we carried it to the reserve. Well, now it is exactly the same story here. This account as it stands reveals—well, not a very satisfactory state of things, it reveals a considerable loss on the working of this foreign business. We have had the account made out as you see to 30th June, 1885, and you will remember that this meeting has been adjourned from time to time. It ought really to have taken place much earlier, but it was adjourned in order that we might have an opportunity, if possible, of doing abroad what we have done at home, put our horses together with our adversaries, and get rid of all the loss and cost of legal proceedings and litigation about patents. As long as litigation is pending about patents between the Edison and Swan or anybody else, the public are subject to all kinds of annoyance, and they do not see their way to enter into what may land them also into litigation. Well, our efforts have not been wholly unsuccessful; on the other hand, they have not been unattended with some encouraging results. We have two combinations of people to deal with. Mr. Edison, or Mr. Edison's friends, sold his patents, some to a German combination, having its seat in Berlin, and some to a combination in Paris, which controls France, Austria, Italy and some other countries. With respect to the Berlin business, where we were in more active competition than in any other place, we have had litigation pending now for some considerable time. Well, it is exceedingly complicated. We had there, as we had in England, the very best advice that it is possible to get. We are advised that our patents are not an infringement of the Edison patents, but that they are self-standing. Of course, the other party contend they are infringements, and that we must be "injuncted," and we are at present pretty much in the position of litigation that we are working practically with an injunction about our necks. We are told, notwithstanding all, that we shall succeed. We thought we might impress our German competitors with the wisdom of what we had done in England, because there we were competing, and we were in litigation. Fortunately litigation being pending in England, we were enabled to persuade each other that the wisest course was to amalgamate our interests on reasonable terms, and we came together, litigation stopped, the companies became much stronger united than they were when fighting against each other, and we are going on doing a very sound business in England. Well, we have taken a good deal of trouble to induce the German people to come into some sort of an arrangement, but the conditions they sought to impose—in fact, the terms—were so exceedingly unsatisfactory, that we could not accept them, and acting upon the advice of those experts whom we are obliged to rely upon in Germany—lawyers and others—we determined to wait the issue and hear the appeal which is coming on on the 27th of this month against a judgment of an inferior Court, which has so far gone against us. That Court—a Court of first instance—have delivered judgment, oddly enough, distinctly opposed to the view of the Patent Office of Germany. They were consulted as to whether this Swan invention was or was not an infringement of the Edison. Well, they are an official body, having no interest in the matter, highly skilled, technical people, even more so, I suppose, than our own Patent Office, and they pronounced a judgment distinctly in our favour. However, the Court in the first instance did not agree with the Patent Office, and they have so far said they believe we are infringers. Of course we have appealed, and the appeal will shortly be heard. You must not attach too much to it. We have most eminent patent lawyers at our backs, and we are told that we shall succeed. Well, we shall know before long. Our friends opened their mouths so wide that we did not jump down them, and that part of the business remains as it was. We fear as regards the Edison Company in Germany that it looks as if the suits must be fought out. Well, with respect to the other combination, we have had several interviews in Paris and in London; and, although I am not in a position to say that we are agreed, we are within what they call "measurable distance" of agreement—that is to say, we might think it worth our while to accept the terms which, as the result of negotiation, have been suggested to us as counter terms to our own. We do not at present feel quite inclined, and something will turn upon the result of this appeal in Germany; but there is a prospect, and I think a very good prospect, of our being able to come to an arrangement with the Paris Edison Company, controlling France, Italy, and some other countries, of an advantageous character—in fact, doing what we have done here, making a fusion of interests, and working together, not in competition, but in accord. Now, that is what I may call the political position of the matter. Another advantage of having deferred this meeting upon two occasions is that we are enabled to bring down the statement of accounts to the end of the year. Perhaps I had better just go through the report, because that will bring the matter in regular order. We have told you in the first paragraph that of the last report of the Edison and Swan Company we have said nothing in this report, because we thought it would have been fresh in the minds of the proprietors, who had a full report sent to them; but I referred to that as far as I thought it necessary in my opening remarks. With respect to the second paragraph I have told you it comments upon the position of these negotiations or litigation abroad. When we come down to paragraph 3 we deal with the substance of these accounts for the year ending 30th June, and you will see what it is. The best plan, I think, will be to go the account itself. If you look at the profit and loss account you will see what the essence of the whole matter is. You will see there that on the one side of the account the stock on the 1st of July was £4,187, and you will see the different transactions, purchase, expenses—very heavy expenses—wages and expenses of the factories, depreciation and reserve for doubtful debts, there is a total on that side of £32,484. On the opposite side you will see sales, &c., less commission and allowances, transfer fees, interest, &c., stock on 30th June, 1885, the balance being less £6,258. Well, now, at first sight that looks rather startling, and if there were not some circumstances which would make it more or less palatable, it would be very serious. It is quite serious enough as it is, but it would be very serious if it could not be explained. It so happens, however, that in that particular year our business was entirely suspended by the fire at Lille, a factory which we were called upon by the state of the French law to construct in order to manufacture and in order to maintain our patents. Another factory we had to start at Kalk, in Germany, near Cologne, precisely on the same grounds. The Lille factory had barely got to work when it was burned down, and, of course, the whole process of manufacture was stopped for a considerable time, and there we were with the rent upon our backs, the taxes, and the establishment, because with great difficulty we had got these people together. They are not to be picked up in the streets, as very few understand the process of manufacture, and we had them on our backs, although for a very long period of that year they had little or nothing to do. That is the reason the cost of production was enormously increased. Further, in order to get the customers supplied (because at this Lille factory we not only burned down our factory, but our large stock of lamps was also destroyed) we had to purchase lamps of the parent company, the Edison and Swan Company; and the Edison and Swan Company, although affiliated with the Swan Company, did not consider it their duty to hand us lamps at prime cost. We made a reasonable bargain with them, and sold a considerable number of the lamps at what to us was a considerable profit. There were two items which told against us—we had to buy lamps at a price beyond the ordinary cost of production to sell to our customers abroad, and our outturn of the balance of lamps in those factories was very greatly increased by the fire at Lille, by the fact of opening and starting a business at a new factory in Germany, where it takes a long time to get the output to a figure which is profitable. The balance-sheet, however, is not as bad as it looks, because the stock of lamps on hand on the 30th of June, put down at £7,000, is estimated at the price of production; but of course they have been produced on the assumption that they will be sold, and they will be sooner or later. You cannot carry on a business of this sort without a large stock of lamps on hand of a great many varieties—lamps of different candle-power. In fact, there are a great number of different lamps, and though you may have some thousands of lamps in hand they are divided into so many categories that the number in each category is small. It would not be polite to bring in the credit of the account the selling price of the lamps, and we bring them in at cost price as an asset, the theory being that they are worth, at any rate, what they cost to produce, the fact being that probably they will realise considerably more. But taking that as a reasonable business calculation, that £7,000 represents the saleable value of very much more, probably nearly twice as much—if that be so that balance being loss would disappear. I wish you to think that out—that of necessity when we make up our accounts we must have a large stock of lamps on hand which have been produced, which means wages, rates, and material (and material is an expensive thing in these lamps). All that has been expended and comes to the debit of the account. On the other side, we do not put in the profit in profit and loss, but merely the cost of production. Therefore, from that point of view, that account may be made, if you understand it, much more satisfactory than it seems. It would really leave us probably nearly a balance—there would be no gain, but there would be no serious loss. Dealing with the general state of things, I wish to carry you up to the assets of the Company. You see the share capital—19,750 fully-paid shares, and 79,934 shares of £5 each, with £3. 10s. each paid, less balance of instalment not due till 1st July, and calls in arrear. This account that we are now dealing with was made up to the 30th June, 1885, but presently I shall have the pleasure of telling you the result of six months later. At 30th June, however, we had got £360,000, represented by shares fully or partially paid. There is a small profit on cancelled shares, and there are sundry credit balances. On the other side there are patent rights, £104,000, awfully in excess of what ought to have been paid; but there it is. It is very easy to be wise after these periodical manias which seize the public, when they are induced to give a great deal more for patents than the patents turn out to be worth, or may turn out to be worth. Then the next items are the outlay on factories, plant, furniture, &c., less depreciation (a small item), £7,548. Then, our shares in the Edison and Swan Company—that is, the asset in the British Company that I spoke of before—£208,478. Sundry debtors were £7,634, and stock on hand £7,110. That is the stock I have been telling you about, which is brought into profit and loss account at the cost of production, and brought into the balance-sheet as an asset at that value, not at the selling price. Then there is a loan on security,

Digitized by Google

£11,000, and cash on hand and at the bank £8,000. That is £19,000. Next comes the balance from the profit and loss account £6,258, and the loss from previous years £2,327, showing a loss on our business of £8,585 up to 30th June, 1885. Added to that you have the loss by the fire at the Lille factory £1,094. I do not know whether anyone here knows much about French insurance business, but it has been my misfortune to have something to do both as a shareholder and an insurer in a French company, and they manage in a wonderful manner to wriggle out of their obligations. We thought a considerable portion of that would be covered by insurance, which we effected through proper agents in the usual way. However, the French Insurance Company found that they could get out of it, and we were face to face with a suit, and we had to compromise the matter. We thought it better to lose a considerable amount of the sum insured rather than get into litigation with the French Company. We made up our minds that it was advisable that the Paris factory should be shut up. There was business, but there was no profit, and we thought it better to wipe off the loss there, which we did. In fact, we have been doing abroad what we did at home with so much benefit to the Edison and Swan Company. We got rid as rapidly as possible, and on the best terms possible, of bad bargains. That brings down the loss in the working of this concern to £10,800. That is not very satisfactory, but it is subject to two qualifications. One I have pointed out—that there is out of the balance-sheet and out of profit and loss account a tangible value not brought into book at all—the selling price of the lamps as distinguished from their cost price. That would go far to modify that loss. The other point is that you have paid several thousand pounds for learning the pitfalls of this business. That is another thing. One has always to pay for that; and as far as I am able to estimate this thing, from a great deal of experience (and Mr. Leyland and my colleagues will bear me out), we think it is a very good get-out of the difficulties by which we have been surrounded. In consequence of the postponement of this meeting, hoping that to-day we might have something tangible to report as to our negotiations, we have availed ourselves of the opportunity of bringing down a profit and loss account to the end of the year, and we have finished a supplemental account, going up to the 30th of September. We have increased our stock of lamps abroad at these two factories, and the dead value lying upon those lamps at this moment comes to £10,234, upon a very moderate estimate indeed. By experience we have proved that in the year we sold a very large number of lamps at the average rate of 3s. 8d. We have carried into the balance these lamps at a shadow under cost. We have taken them in at half the saleable price—rather under—at 1s. 9d. It comes to this: We hope that those lamps will be sold, and having got that stock up to a sound normal condition we shall not add to it more fully than is necessary to keep up what is called the balance of stock from half-year to half-year. I am now telling you what the factor is. It turns upon this—have we touched bottom? We have learnt a great deal. We have got the means at our fingers' ends of diminishing the cost of this output, because the greater the output the less the proportion of the cost of the lamp; and we have got a trade which we trust is growing—slowly, less rapidly than we hoped, but which will develop, we believe, with much greater rapidity once we can get rid of the litigation. There is no doubt that both in Germany and France that does stop the consumption of these lamps. People come to us and say, We want 10,000 lamps, but will you guarantee us against litigation? Will you guarantee us, as users of an alleged infringed article, that the Courts will not come and persecute us or send in their instruments to take away and destroy the lamps (because that is what they do in Germany)? We say no, we cannot undertake such business. If you like to take the lamps subject to legal risks, you can. We are both sufferers from that state of things. Many persons in Germany will not buy Edison lamps because they know the Swan interest is suing the Edison Company, and many will not buy Swan lamps because they knew the Edison Company are suing the Swan Company. Well, one does not like to get into the habit of predicting things, but one is bound to have the courage of one's opinion, and particularly with shareholders who cannot have the same means of forming a judgment as we have. Our opinion is that this thing is now as bad as it can be, but that we have got in hand an asset quite sufficient to wipe down the loss on the business up to this moment, and that the probabilities are strongly in favour of our being able to go on and turn a present loss into a future profit, and that very rapidly. That is prediction, and you must take it for what it is worth. My colleagues will all agree in that view. We give it to you perfectly *bonâ fide*. We ourselves are very largely interested in the success of this thing, and, therefore, both our pockets and our reputation are concerned; because we feel that we have been very much trusted by the proprietors in these companies, and it is our duty on that ground alone, without the other incentive, to get our money back, that makes us go into this thing very deeply, and makes us present to you our views, in a perfectly straightforward way, in this manner. Paragraph 5 in our report says:—"Heretofore the accounts have been made up to 30th June in each year; the Directors propose that the financial year shall in future end on 30th September, and for that reason they now present the accounts to the shareholders for fifteen months." We have given a supplemental account. The reason of this proposed change is, as I said before, that you are enormously interested in the Edison and Swan Company, and that company will make up their accounts to the 30th of June, and they, I suppose, will hold their meeting between the 30th June and the 30th September. And who knows—they might have a dividend to declare. If they had a dividend to declare you would stand in for a very large percentage of it, because you are much the largest holders in that Company—to the extent of £280,000. Well, we could not state our position without bringing into the credit of our accounts for the current year the results of the working of the British Company, in which we have so large a stake. We have therefore thought it better that our accounts should be made up to the 30th September, as the result will affect our common purse. In paragraph 6 we refer to the question of the distribution to the shareholders of the shares allocated to this Company in the Edison and Swan Company. We are very anxious to be relieved of the enormous responsibility of holding these shares in trust, but there are great difficulties about distributing them at present. We could not distribute them at once without involving ourselves in a question of considerable gravity, and you must again be good enough to rely on the judgment of the Board and their solicitors, that it is much better to let the matter stand where it is at present. The two retiring directors are Mr. Swan and Mr. Stearn, as to whom there will be a resolution. With what I have now said, subject to answering any questions, I now move the adoption of the report and accounts.

The DEPUTY CHAIRMAN (Mr. F. R. Leyland), in seconding the motion, alluded to the changes made at the Board at the last general meeting, when he was one of the two new Directors who were appointed, and to the measures which were subsequently taken for placing the affairs of the Company in a more satisfactory position. He also referred—following the Chairman—to the exceptional causes which had led to the loss shown on the working of the year to June, 1885, and to the other items which had gone to increase that loss. From that period he considered that they had started fair, and the accounts for the next quarter, up to September, 1885, had been made up, and showed a very satisfactory profit—a profit on that one quarter of £3,206. Nor was that to be taken as an exceptional profit, for the accounts had also been made up—though they were not passed or audited—for another three months, and they had found that the result was rather more profitable than had been the case in the September quarter. There was no doubt that the business was a profitable one; but it was quite clear that the whole thing depended upon the result of the litigation referred to, and whether they could hold their patents. Speaking of the distribution of the shares of the Edison and Swan Company among the shareholders, he pointed out that it was impossible to take that proceeding so long as litigation was pending, and that there was the question to be considered, prior to the distribution taking place, of the position occupied by those who held fully paid and those who held partly paid shares.

After a few remarks from Mr. FOSTER, and a reply from

The CHAIRMAN, who explained again how the profit of the September quarter had been arrived at, the motion was unanimously adopted.

Resolutions were afterwards passed re-electing the retiring Directors, Messrs. J. W. Swan and C. H. Stearn, and the auditors, Messrs. Quilter, Ball, and Co.; and a vote of thanks to the Chairman brought the proceedings to a close.

NOTES.

BRITISH GUIANA.—The cable between Trinidad and Demerara is interrupted.

PARA.—Telegraphic communication with Para is suspended, the cable between Maranham and that place being interrupted.

BURMAH.—Advices from Rangoon state that the construction of a telegraph line to Yemethen will be commenced immediately.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th March amounted to £2,544.

ELECTRIC LIGHTING BILLS.—The amendment Bills of Lord Rayleigh and Lord Bury, as well as the Government Bill, have been referred to a Select Committee.

THE RIOTS IN BELGIUM.—Considerable injury has been inflicted on the telephone system in the disturbed districts of Belgium by the workmen on strike, who have wantonly cut the wires.

PERSONAL.—We are informed that Mr. J. S. Raworth, formerly agent to Messrs. Siemens Brothers and Co., has been appointed superintending engineer to the Anglo-American Brush Electric Light Corporation.

THE RECENT GALES.—Much damage has been done to telegraph and telephone wires by the boisterous winds during the present week, especially to over housetop wires in the towns of Lancashire and Yorkshire.

THE BROOKLYN ELECTRIC COMPANY.—This company has been incorporated for the sale of electricity, lamps, and electrical apparatus generally. Its capital stock is £10,000, consisting of £500 shares of £20 each.

THE ELECTRIC LIGHT AT MODANE.—This small Alpine town of only 2,400 inhabitants has followed the example set last year by the equally small town, La Roche-sur-Forva, and has now its streets lighted by electricity.

SOCIETY OF TELEGRAPH-ENGINEERS.—The next meeting will be held at the Institution of Civil Engineers on Thursday, 8th inst., when the discussion on "Electric Lighting by Means of Low Resistance Glow Lamps" will be continued.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th March were £2,099, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

TELEGRAMS FOR CHILI.—From the 1st April the rate for telegrams to all places in Chili, by the routes of the Anglo-American, Direct United States, Paris and New York, Western Union, and Commercial Cable Companies, will be 10s. 4d. per word.

TELEGRAPHIC ACCOMMODATION.—Mr. A. G. Ing, who, on behalf of the inhabitants of Manor Park recently forwarded a memorial to the General Post Office, asking for the establishment of a telegraph office at Manor Park, has received a letter stating that application has been made to the Lords Commissioners of the Treasury for authority to carry out a telegraphic extension to Manor Park, and upon this being obtained the work will be put in hand.

GLOBE TELEGRAPH AND TRUST COMPANY.—The directors at the board meeting held on 30th March declared the payment of an interim dividend on and after the 19th inst. of 3s. per share on the Preference shares, less income tax, and of 1s. 6d. per share on the Ordinary shares—the income tax having already been deducted—for the quarter ending the 18th inst. The transfer books were ordered to be closed from the 12th to the 19th inst., both days inclusive.

ELECTRIC RAILWAY BRAKES.—The *Bulletin International de l'Electricité* calls attention to the recent experiments of M. Regray, on the Eastern Railway of France, which proved the great power of electric brakes. In fact, the fault to be found with these, notably with Achard's brake, is that they act too suddenly. Our contemporary thinks that the late accident at Monte Carlo might have been, if not entirely avoided, at any rate greatly mitigated, if the trains had been fitted with electric brakes.

MAST LIGHTING IN AMERICA.—The new Chamber of Commerce in Chicago has the distinction of being directly under the rays of a cluster of arc lamps which for brilliancy and height are remarkable, even in the United States. On a tower of 330ft. in height is placed a mast, carrying at the top four arms, each 14ft. long, arranged in the shape of a cross. From the ends of these arms is suspended an iron corona, 30ft. diameter, and from this are suspended twenty 2,000 candle-power lamps. Corona and lamps are let down for trimming in the usual way. It is said that the light is visible to a distance of 60 miles.

COLONIAL AND INDIAN EXHIBITION.—Her Majesty the Queen has been graciously pleased to intimate her intention of opening the Colonial and Indian Exhibition, on Tuesday, May 4th. H.R.H. the Prince of Wales, Executive President of the Royal Commission, accompanied by H.R.H. the Duke of Connaught, a Royal Commissioner, visited the various sections of the Exhibition on Monday morning. Sir Dighton Probyn, Colonel Ellis, Mr. Francis Knollys, and the Hon. Major Egerton were in attendance. Sir Philip Cunliffe-Owen, the Secretary to the Royal Commission, received their Royal Highnesses, and conducted them over the buildings.

LINCOLN'S INN INSTALLATION.—The lighting of Lincoln's Inn hall, library, and council rooms was carried out last autumn by Messrs. Clarke, Chapman, Parsons and Co., of Gateshead-on Tyne. The installation consists of about 220 Swan lamps of 20 candle-power, receiving current direct from one of Parsons' turbine electric generators governed by an electrical control-governor of great accuracy. The absolute steadiness and perfection of the light was much admired by the distinguished company present at the annual dinner of the Institution of Civil Engineers last week, under the presidency of Sir F. Bramwell, His Royal Highness the Prince of Wales being one of the guests.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA COMPANY. We are informed that the accounts of this company to the 31st December last show, subject to audit, a balance of profit of £164,188 after payment of three interim dividends, and a bonus of 2s. per share for the first half year, and charging £55,062 against revenue during the year on account of cable renewals, &c. The directors now propose to pay on the 15th inst. the usual dividend of 2s. 6d. per share, together with a bonus of 2s. per share (both free of income-tax), making, with previous distributions, a total payment of 7 per cent. for the year 1885. The balance of £41,625 has been carried to the reserve fund, which now stands at £567,802.

THE ELECTRIC LIGHT IN THE CAPITOL AT WASHINGTON. The *Electrical World* reports that the Edison lights in the

Digitized by Google

Capitol at Washington are giving great satisfaction. The chandelier recently placed in the Senate marble rooms, substituting the Edison lamps for gas jets, was lighted on March 6th for the first time. There are twenty-four burners encased in varied coloured glass representing tulips. The design of the chandelier is a massive basket of flowers and ferns. The Edison light is now exclusively used in the Senate wing, even the elevator being illuminated by an incandescent lamp. In the cloak rooms of the house and in the library under the gallery these lights are now being used with pleasure to all.

The Electric Light in Mexico.—The *Boston Herald* gave recently an interesting account of artificial lighting in the City of Mexico. It appears that gas which is made from resin costs 24s. per 1,000 feet, and is very inferior in illuminating power to gas made from coal. At present there are 60 Brush lights in use, but the corporation are about to contract for a large extension of electric lighting. There will be 10 towers, each carrying four 4,000-candle lamps, and in addition there will be two hundred 2,000-candle arc lamps distributed throughout the city. The Brush and the Thomson-Houston Company are competing for this work. Since fuel of any kind is very dear in Mexico, the question of efficiency of dynamos and lamps is of the greatest importance.

House Lighting by Primary Batteries.—M. P. Juppont, in a little book entitled *L'Eclairage Electrique dans les Appartements*, sums up this subject in the following words :—"Lighting by primary batteries is only applicable on a small scale. Since its cost is too great, as compared to other methods of lighting, it will only be undertaken by amateurs who can fit up their own lights, and find a pleasure in watching the batteries and keeping them in order. Outside of such and other cases where the light is used as a luxury, there is no general application for batteries as regards lighting. It may be that the problem of economical lighting by primary batteries will be solved by an ingenious inventor shortly, but it may also be that we shall have to wait for this many years. Meanwhile, the incandescent lamp fed from a primary battery is simply an article of luxury."

Abbreviated Addresses.—In reply to Mr. Labouchere, in the House of Commons, last Friday, Mr. H. Fowler said :—"It is found that the fee now charged for registering telegraph abbreviated addresses does not cover the cost to the department and the loss of revenue by the curtailment of the address. At the same time the use of abbreviated addresses leads not only to delay in the delivery of messages with abbreviated addresses, but also necessarily causes delay in the delivery of messages containing a full address. The use of abbreviated addresses is detrimental to the general public, interferes with the regular working of the telegraph service, and increases its cost. Since the introduction of the sixpenny tariff, the practice of registering addresses has so enormously increased, and the departmental difficulties which have arisen have been so great, that it is a question with the Postmaster-General whether, after a certain date, it would not be well to abolish the use of abbreviated addresses, at all events for inland messages, and he cannot, therefore, lessen the present charge."

Lighting at Madrid.—The Madrid Gas Company and the consumers of gas for lighting purposes are just now engaged in a contention upon the question of the quality and price of gas, which, according to the latest Spanish advices, appears to be arriving at an acute stage. A committee has been appointed by the consumers, many of whom have announced their intention to abstain entirely from using gas should the committee, in the event of not finding their representations successful, recommend such a course. Meantime the dispute has been taken up by the Madrid Mercantile Club, a body representing a great majority of the Madrid merchants, and standing somewhat in the position of our Chamber of Commerce, though its action is generally confined to the discussion of local matters. Its official organ in the Press, *El Camercio Espanol*, in its issue of March 27, contains an invitation in the name of the trade and industry of Madrid for lighting the city by any process, either native or foreign, which will supply a cheaper and more efficient light than that of coal gas. Applicants are requested to forward all particulars as early as possible to the Madrid Mercantile Club.

Telegraph Revenue.—From the Revenue Returns published yesterday for the financial year ended 31st March, we give the following particulars relating to the telegraphs :—The gross revenue for the undermentioned periods in 1884-5 and 1885-6, was

1884.			1885.	
June 30	£440,000	....	June 30	£445,000
Sept. 30	485,000	....	Sept. 30	490,000
Dec. 31	430,000	....	Dec. 31	410,000
1885.			1886.	
Mar. 31	405,000	....	Mar. 31	395,000
	£1,760,000			£1,740,000

These figures show a decrease of £20,000 on the gross receipts for the whole year, compared with the year preceding, but are exactly that amount in excess of what it was estimated they would yield. The gross falling off in the last two quarters, during which period the sixpenny tariff has been in operation, was £20,000 and £10,000 respectively, making a total decrease of £30,000 for the half year. Against this is set the increase of £5,000 for each of the first two quarters, making the gross decrease for the whole year £20,000 as compared with 1884-5.

Patents in Germany.—A recently issued number of the German *Patentblatt* contains some interesting statistics as to the number of patents taken out in 1884, 1885, and during the period from 1877 till 1885. The figures are as follow :—

	1884.	1885.	'77 to '85.
Applications for patents	8,607 ...	9,408 ...	63,585
Applications published.........	4,632 ...	4,456 ...	38,886
Refused after publication ...	357 ...	358 ...	2,494
Patents granted	4,459 ...	4,018 ...	34,561
Withdrawn patents	18 ...	25 ...	163
Expired patents	3,984 ...	3,947 ...	23,365
Patents in force at end of year.	10,994 ...	11,046 ...	11,046

Of purely electrical patents there were :—

Applications	292 ...	387 ...	1,996
Patents granted	256	156 ...	1,086
Expired patents	— ...	— ...	621

On an average there are 54·41 per cent. of the applications granted, and for every 100 patents granted 57·18 patents expire. The small number of patents refused after publication shows that the German examiners do their work very rigorously, not accepting for publication any patents but those which can reasonably be supposed to be good, and therefore not easily upset by opposition after publication, and before the patent is finally granted.

Lighting Flour Mills.—We are informed that the Maxim-Weston Company have just completed the lighting of the extensive new flour mills at Newcastle the property of Messrs. Robert Hedley and Co. The following is their account of the installation :—"Our lights are all 20 candle-power lights, which are suspended from the joists some 10in. or 15in., and usually are so placed in clear positions as to light a space

Digitized by Google

equal to 15ft. by 15ft. On the roller floor the lamps are numerous, a good light being required in this department, and are placed in a line as far as possible and between the different lines of roller mills, thus securing a full diffusion of the light. The distance apart varies from 10ft. to 16ft., according to the placing of the machine. On the centrifugal and reel floors they are placed between every two machines, admission being thus obtained from one side or the other to all machines, whilst portable hand lamps supplied to us by your company, according to specification, enable an examination to be made into the interior of any machine with safety. In warehouses one 20 candle-power lamp to a space of 15ft. by 30ft. will be found sufficient. Generally, the light keeps the interior of the mill cool. We adopted the light after a careful calculation of comparative cost of gas and electricity."

The Electric Light at the Law Courts.—Our daily contemporaries have—as is usual with scientific matters—very much bemuddled what, after all, is but a simple matter. A few days ago one or two of the incandescent lamps fell to the ground, or rather one of them fell upon a gentleman in the Vice-Chancellor's court. Sir James Bacon thereupon sent for the electric light engineer, and required explanations. It seems that the evil arose from a screw in the fittings being rather small, and the expansion of the materials surrounding the screw caused the threads to lose their hold and the screw to draw. The daily papers imagine that a screw passes through the top of the glass, but of course all electricians know that this is incorrect, though the general public may not be so well informed. We cannot agree with the Vice-Chancellor that the engineer was to blame, for we should imagine that this matter would be altogether out of his jurisdiction. It may be as well to inform our political contemporaries that the only metal which contracts and expands in a somewhat similar manner to glass is platinum, and that this metal is far too expensive to be formed into ordinary screws. We should advise a little more scrutiny into the scientific aspect of the case before rashly commenting upon a subject evidently outside their range of understanding.

City and Guilds of London Institute.—The sixth annual meeting of the governors of this institution was held on Wednesday afternoon, at the Mercers' Hall, Cheapside, the Earl of Selborne presiding. Lord Selborne, in moving the adoption of the annual report, read a letter from the Lord Mayor regretting his inability to be present at the meeting, and remarked that the institution had now reached the most critical stage of its history. The buildings of the central institution were completed, and every branch of the institution was practically for the first time in full working order. There was great difficulty in connection with trade both in this country and on the Continent, and that should stimulate them to make the wisest and best possible use of every possible means of improving the condition of the workmen. During the past year examinations had been conducted in 167 centres, and 3,968 candidates presented themselves for examination in 42 subjects, of which 2,168 passed. Their average yearly income was £24,000, and, if the work was to be properly carried on, at least £30,000 would have to be raised. Sir Frederick Bramwell seconded the adoption of the report, which was ultimately agreed to. It was also decided, on the motion of Sir Sydney Waterlow, to empower the council to borrow on mortgage a sum not exceeding £25,000 for the extension of the Finsbury Technical College.

The Municipal Authorities in Vienna and General Supply of Electricity.—It seems that the monopoly enjoyed in Vienna by the Imperial and Continental Gas Association, as far as lighting by gas is concerned, has induced some members of the municipal council in that city to view with suspicion the action taken by the Association with reference to the erection of a central electric light station. They fear that the general supply of electricity may thus become as much a monopoly as the supply of gas already is, and that the money which the consumers will have to spend for the luxury of having the electric light laid on will thus flow out of the country and into the exchequer of a foreign company. To prevent this the councillors would prefer that the town should erect its own central electric stations and supply its own wants. This view has been endorsed by the whole of the municipal council, who on the 3rd of November last passed a resolution agreeing in principle that central stations for the public supply of electricity are to be erected and managed by the town authorities. Other resolutions were also passed instructing the local board to report whether certain buildings and sites could be employed for this purpose, and also whether the water-power of the Danube could be utilised. It is expected that Parliament will be asked to sanction a public loan of £50,000 to £60,000 for the purpose of erecting central electric stations and other necessary works.

Telephone at Bournemouth.—On Friday afternoon last week a large number of influential residents of Bournemouth assembled at the local head-quarters (1, Adelaide-terrace) of the Western Counties and South Wales Telephone Company, the object of the gathering being to open the newly-established Telephone Exchange. Amongst those present were Captain Hartley, Mr. Fisher, Mr. C. C. Creeke, Mr. E.W. Rebbeck, Mr. W. Scott Evans, Mr. C. A. D. George, Mr. J. R. Ridley, and Mr. R. W. Sworn, members of the Bournemouth Improvement Commission; Mr. Jas. Druitt, jun., clerk to the commissioners; Mr. G. R. Andrews, town surveyor; Mr. H. A. Garrett, assistant surveyor; Dr. J. Roberts Thomson; Messrs. Bacon, Primavesi, Hankinson, Lane, Laidlaw, F. Wareham, Dunn, Hervey, Redfearn, Carr Gibbs, Dale, H. Nash, N. S. Jenkins, Nethercote, J. Worth, E. Worth, Bicker, Pyle, Helyer, J. J. Allen and others. Mr. H. F. Lewis, general manager and secretary to the company, said it was only five months since he came first [to Bournemouth with the view of opening a telephone exchange. He had an interview with Mr. Newlyn, who received them cordially; and he had to thank also the commissioners for their consideration and courtesy. They were also indebted to the inhabitants generally and to those gentlemen especially who had assisted them by becoming subscribers. All he could say was that the company on their part would do their best to deserve the confidence reposed in them. They had at the present time 41 exchange orders, and five private line orders. Nine of them had been connected, and five would be in speaking that day. The lines which were not yet connected would be pushed forward as rapidly as possible. Mr. J. Druitt (in the absence of the Chairman of the Commissioners) then opened the exchange.

Conductivity of Mixtures of Organic Compounds.—M. Bartoli has noticed, says the *Journal* of the Chemical Society, that although generally the electric conductivity of carbon compounds diminishes almost to zero at or about their points of solidification, yet certain mixtures and solutions of these compounds show an increase of conductivity at temperatures below that of the solidifying point, and a subsequent decrease to zero at a lower temperature. This phenomenon is not noticable in mixtures of natural origin, such as the oils, wax, balsams and resins, but only in artificially prepared mixtures and

Digitized by Google

solutions, such as napthalene with one of its derivitives, napthalene or paraffin with phenol, phthalic or benzoic anhydride, and the acids of the acetic series. In this paper tables are given illustrating this phenomenon. As regards its explanation there are two possible cases to be considered—first, that of a mechanical mixture, such as paraffin in annyl alcohol (or acetic acid); second, that of the mutual solution of the two components, such as naphthalene in one of its derivitives. In the former case the interdiffused liquid would have a constant conductivity independent of the temperature up to the point of its own solidification. A simple case of the latter is the solution of a small quantity of a conductor in an insulator; such a material shows two points of solidification, the one near to that of the more abundant constituent, the other immediately below. Between these two points there is a sufficient amount of conducting liquid interposed between the solid particles to admit of the passage of the current; but this gradually diminishes with decrease of temperature. This explanation is not, however, valid for compounds such as phenol and benzamide, which possess a certain amount of conductivity at temperatures far below that of their solidification.

EARTH CURRENT STORM.—A very wide-spread earth current storm has been felt upon our various telegraphic lines. The following references show the experiences with the storm eastwards. We should be glad if some of our readers can supplement the information by giving us references westward:—

London... First observed at 8:20 a.m. on the 30th March, and terminated at 11:15 a.m., stopping work for some time.

India ... Earth current storm lasted from 2 to 5 p.m. 30th March, Indian time; strongest in the Bombay Presidency, and stopped working between Bombay and Madras.

Madras... Strength of current on Madras-Penang cable = 1 milliampere; but unable to get exact reading owing to rapid changes of polarity.

Singapore. Strong earth currents on Java cables from 3 p.m. on 30th March. Unable to work on Penang cable up to 7. About 10 became fainter on all lines, and disappeared at 7 a.m. on 31st March.

Zante .... Strong earth currents all day on 30th on Corfu, Otranto, Trieste, and Candia cables.

Gibraltar.. Strong earth currents on Lisbon and Villa Real cables, morning of 31st March.

Madras... Earth current disturbances again observed on Indian land lines at 5 a m. on the 31st March, lasting half an hour.

London... Earth currents were again observed in London on 31st March, during the morning.

Curiously, no earth current disturbances have been observed in Egypt. The cables have throughout been less affected than the land lines, owing to the use of condensers.

TELEPHONE EXPERIMENTS.—Some interesting experiments, says the *Newcastle Daily Journal*, were carried out at the offices of the Northern District Telephone Company, Sunderland, a few evenings ago. Two different types of instrument were used, one of which is known as the "loud-speaking telephone," and the other as the Blake Transmitter and Bell Telephone Combination, the latter being the instruments supplied by the Northern District Company. The experiments amply demonstrated the superiority of the latter instruments over the "loud-speaking" ones, as conversations were carried on with much greater ease, and songs and recitations were heard more distinctly than was the case with the "loud-speakers." The telephone can hardly be termed a new invention, and yet, though it is becoming very generally adopted, not only for commercial purposes, but also for domestic uses, there is still a large portion of the community who have not even seen this scientific marvel of the age. As an instance of the variety of ways in which the telephone can be employed, it may be mentioned that a gentleman in one of the rooms was singing a song, whilst the party referred to were listening in another part of the building, and at the same time the manager of the company was listening at his own residence, about a mile away. The song was unfortunately pitched in too high a key, and the executant did what many other more ambitious performers have done, viz., broke down. Successive efforts to select a key which would bring the range of the song within his compass having failed, the manager of the company struck the proper note on his piano, and the song proceeded without further mishap. We are given to understand that this company are making very rapid progress in this district, and that the Tyne and Wear will shortly be in speaking communication with Durham, Darlington, the Hartlepools, Stockton, and Middlesborough.

HER MAJESTY'S NAVY.—Messrs. R. E. Crompton and Co. have been entrusted with the order for wiring the two new gunboats now being rapidly completed at the Devonport Dockyard—viz., Her Majesty's ships "Landrail" and "Curlew." The work was given to Messrs. Crompton on their undertaking to complete one boat—the "Curlew"—in six weeks. As each ship is only to be fitted with about 85 incandescent lamps and search lights, this would appear an easy matter to any one not well acquainted with the difficulties involved. The contract, as is now usual with such work for the Admiralty, includes supplying, fixing, and fitting all teak casings for the wire leads, and drilling all holes, piercing decks, &c., also fixing all fittings, switches, cut-outs, &c. It is, of course, well known that on all war ships of recent design space of any sort is of the utmost importance; but such a generalisation as this conveys an utterly inadequate impression to the minds of the uninitiated as to the difficulties to be overcome by the electrical contractor in such cases as the "Landrail' and "Curlew." It is no exaggeration to say that every available space is already occupied either with steam pipes, water pipes, ventilating pipes, speaking tubes, gun firing circuits, bells, signals, and gear of every description, and owing to the existing fittings and the rigorous rules as to piercing water-tight bulkheads, it is frequently necessary in order to carry the wires through a space sometimes not exceeding a few inches, to turn them upwards through one or more decks, sometimes of steel, until a suitable place is found, and then descending, sometimes through the same decks, the wires are at last placed in the necessary position and an uninterrupted run of a foot or two may be gained before the next difficulty has to be overcome. When it is further borne in mind that in the majority of positions in which the wires are fixed it is quite impossible for even a small man to stand upright, and that in some specially cramped places even sitting down between decks is a tight fit, it may fairly be concluded that the contractors have no easy task to perform, and that the electrical engineer's lot under these conditions is none too happy; indeed, were it not for the able assistance and advice generally given by the courtesy of the dockyard officials, under all circumstances it would be next to impossible for contractors to take up such work.

ELECTRIC LIGHT WORK.—Messrs. Allsop and Co., stockbrokers, in their circular, say:—"The report of the directors of the Brush Company is altogether satisfactory, and the speech of the chairman at the meeting dwelt very hopefully on their future prospects. Although the action of the Electric Lighting Act of 1882 has hitherto rendered impossible all large enterprises, it is important to note that what may

Digitized by Google

be termed the minor or retail work of this company has constantly increased, and now suffices alone to earn a dividend. This is not only satisfactory in itself, but still more as giving proof of the growing demand for electric light, and an unmistakable indication of the development which may be expected when the removal of legislative restriction shall set free the energies of this company for the valuable and profitable work of public lighting on a large scale. Slow as has been the growth hitherto of electric lighting in England, as compared with that of the United States and European countries, it is impossible to resist the conviction that its progress henceforward is now not only assured, but will in future be very greatly accelerated. Not only for lighting, but for other purposes, there is a greatly increasing demand for electric generators; notably for the propulsion of tramcars and light railway trains. This, at present, quite new industry is destined to have a great extension in the near future, and under the present able and prudent management, the Brush Company will be in a position to avail to the utmost of the impending demand. In point of fact, it has already in view some very extensive work, both for lighting and power. Without desiring to in any way overestimate the future, we may point out that great possibilities always attach to a new and growing industry, and are the reward of the few who early recognise coming developments. It is under this aspect that the position and prospects of the Anglo-American Brush Electric Light Corporation merit the attention and inquiry of those who may be seeking an investment which, while paying a moderate present dividend, contains latent promise of *exceptional* future development." We are not sure that a caution should be given to wait events rather than to be too sanguine. We certainly should like to see "more work" and "more light," and the good time is coming, even if it come slowly.

THE CENTRAL ELECTRIC LIGHT STATION IN DIJON.—The total number of glow lamps at present distributed throughout the town of Dijon and supplied with current from the central station is, according to our contemporary, the *Bulletin International de l'Electricité*, 350. In addition to these there are a very few Pieper arc lamps fed from the same mains. The station was originally designed to receive five 300-light Edison machines, and it was even contemplated at a future date, if the demand for current should have sufficiently increased, to change these dynamos for 500-light machines. But it is evident that the expectations of the promotors have as yet been very imperfectly realised. There are at present only three 300 light machines installed, and that is more than required to feed the 350 lamps which are distributed amongst forty subscribers. These machines are driven by belting from Corliss engines, and the boilers are of the Naeyer type. The mains are naked copper cables carried overhead. It is difficult to understand why the company should not have a far greater number of customers. They have plenty of spare generating power, and are entirely free from the difficulties and risks which have hitherto been almost inseparable attributes of underground distribution. To connect a new customer's house circuit to their mains must be extremely easy, and the work of a few hours. Yet new customers are slow in coming. The reason might perhaps be that the price charged for the light is high, and the manner of charging objectionable. It appears that customers have to pay according to the number of lamps fixed, whether they use them or not. The prices charged are £3. 4s. per annum for each 16-candle lamp, £2. 12s. for each 10-candle lamp, and £2 for each 8-candle lamp. Now, in private installations 1,000 hours per annum is probably the outside limit of the time during which each lamp is in use; and on this basis the electric light would be about two and a half times as expensive as gas light if gas costs 5s. per 1,000ft. To enable their customers to fix a large number of lamps without having to pay for lamps which might be only in use on exceptional occasions, the Dijon Company agree to a number of lamps being put on the same branch wire; and in charging they count, not the number of lamps, but the number of branches by which the house mains are tapped. A suitable switch is placed on each branch, by which any one of the lamps connected with that branch can be lighted; but not more than one lamp can be supplied with current at the same time. This is a device for making the system of charging simply by the number of lamps in use somewhat more palatable to the customer; but we should prefer the use of meters both in the interest of the company and of its customers.

ELECTRIC LIGHT AND POWER LEGISLATION IN FRANCE.—Our neighbours across the Channel, grown wise by watching the disastrous effect of our own Electric Lighting Act of 1882, seem determined not to submit to similar legislation in their own country. With us the key note to legislation was the prevention of a new monopoly; with them it seems to be safety of life and property. Whatever be the object of legislation with regard to electrical industries in France, it seems that the *Syndicat des Industries Electriques* views all attempts at officious interference with suspicion. Such, at least, is our impression gleaned from a very interesting address which M. P. Lemonnier, the president, recently delivered to the members of the syndicate. According to this authority the total capital employed in electric lighting and transmission of energy in France is £2,640,000, of which sum £2,600,000 is represented by electric lighting, leaving only £40,000 to the other application of electricity. In giving these figures M. Lemonnier explains that they represent the capital expended from the time that electric light was first introduced (about ten years ago) up to the present moment on machinery for the generation of electricity, on conductors, and on lamps. The pressure employed varies between 50 and 1,500 volts, and the currents are both direct and alternating. The total number of fatal accidents which have happened during the last 10 years in France, and which are directly attributable to the effect of electric shocks on the human system, is eight. A ninth case is doubtful, as it could not be ascertained whether death was caused by a shock or by the person becoming entangled in a belt. M. Lemonnier points out that in comparison with the capital employed, the electric lighting industry has enjoyed greater immunity from fatal accident than any other industry which could be named, and that there is therefore no need for special legislation by the State for the purpose of more effectually protecting life. As regards the protection of property, he points out that in the opinion of insurance companies, firemen, managers of theatres, and other persons of experience in the fire risks incurred by artificial lighting, electricity is much safer than gas, and no special legislation is needed on that account. He admits that for transmission of energy over long distances, where the cables have to be carried along public roads, or over ground outside the property over which the owner of the installation has control, some kind of legislation as to the manner of erecting and insulating the conductors would be desirable; but he is distinctly opposed to any legislation which would interfere with the details of an installation erected entirely on private ground. He is also opposed to limit the potential in any way, but he would agree to have the kind of insulation necessary for every potential fixed by law.

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(Continued from page 9, Vol. XVI.)

The output of a dynamo is mainly limited by the heating of armature and field magnet coils. The greater the efficiency the less energy will be wasted in overcoming the resistance of the armature and in providing the necessary exciting power for the field magnets; but some energy must always be sacrificed in this way, and the amount so lost is limited not so much by considerations of economy (although in many cases this is also of great importance) as by the capacity of the dynamo to dissipate heat. Say we have two machines of equal size, the one wasting 20 per cent. of the total electrical energy in heating the armature and field magnet coils, the other only wasting 10 per cent. If both machines have equal capacity for dissipating heat it is evident that the more economical machine can give twice the output of the other and yet work at the same safe temperature. This explains why a high coefficient of efficiency is of so much importance in dynamos. It not only enables us to work economically as far as the current expenses for steam-power, or other source of energy, are concerned, but it also enables us to make a small dynamo do the work of a large one, thus reducing the prime cost of the plant.

To make the efficiency and the output of a dynamo high, we have to attend to the three following conditions:—

1. Plenty of copper on the armature and proper cooling arrangements.
2. A very strong magnetic field.
3. An economical shape of field magnets.

These conditions are to some extent opposed to each other. Thus to put the maximum possible amount of copper on the armature we would have to cover it entirely with the coils, and this would prevent the passage of a cooling air current. Again, a very strong magnetic field requires a large amount of exciting power, especially if the thickness of armature conductor is considerable, because a large air space δ (*see* page 8, Vol. XVI.) produces of necessity a large magnetic resistance. The energy required to maintain the magnetic field will therefore be considerable. It is impossible to lay down hard and fast rules for best proportions, as so much depends on the particular type chosen. But by the aid of the formulas given in previous articles it is possible to determine the different items which affect the total efficiency, and by suitably varying the design those proportions can be found for which the sum of all the losses becomes a minimum. Generally speaking, a large armature is advantageous, because it enables us to use wire of large cross sectional area, it has a large cooling surface, and permits the use of internal ventilating passages, and the magnetic resistance of the air space is small on account of the large area of pole pieces which can be used. On the other hand, an increase in the size of the armature increases the cost of the machine rather more than an equivalent increase in the size and strength of the field magnets alone.

The third condition, that of an economical shape of field magnets, can be fulfilled without interfering, to any great extent, with the two other conditions. By the term economical shape we understand such a formation and arrangement of magnets that the energy required to excite them shall be a minimum. Now, in disc machines, there is not much scope for variety in the arrangement of the magnets. The general character in the design of these machines makes it convenient, if not absolutely necessary, to place the magnet cores parallel to and equidistant from the armature shaft around the circumference of the disc. This leads necessarily to a multiple system of magnets with two common yokes, which form at the same time the end plates of the frame. All we can do to minimise the amount of wire in the magnet coils is to make the cores of circular cross section, because of all closed figures the circle is that containing the largest area in a given perimeter. With drum and cylinder armatures the case is different. We have generally two pole pieces, and four different types of magnets can be used.

1. A multiple of single horseshoes, having a common yoke, and two common pole pieces, as in the original Edison dynamo.
2. A multiple of double horseshoes, having two common yokes, and two common pole pieces, as in the original Weston dynamo.
3. A single horseshoe, as in the improved Edison-Hopkinson dynamo.
4. A double horseshoe, as in the Siemens, Crompton, later type of Weston, and other dynamos.

The first and second arrangements are faulty, for the simple reason that the sum of the perimeters of a number of cores of small diameter must necessarily be larger than the perimeter of a single core, the area of which equals the sum of the areas of the small cores. Consequently, multiple magnets require more wire, and absorb more exciting energy than simple magnets.

The third arrangement (*see* page 250, Vol. XV.) is the most economical of all, as can easily be proved by comparison with the fourth arrangement (page 251, Vol. XV.). We found that the strength of field for a single horseshoe is given by the formula,

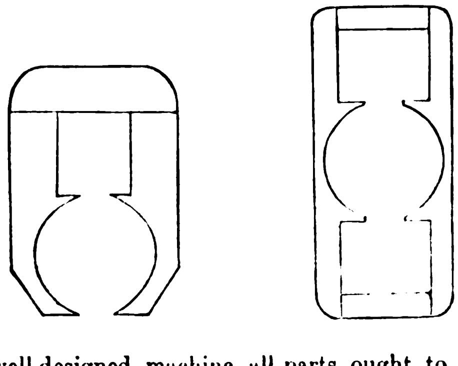
$$Z = \frac{P}{\frac{2\,L}{A\,B} + \frac{l}{a\,b} + \frac{1{,}440 \cdot 2\delta}{\lambda\, b}}$$

If we were to construct an equivalent field of the double horseshoe pattern, L^1 would be little more than half, and the area $A^1\,B^1$ would be exactly half as large as in a single horseshoe, l, a, b, and δ remaining the same, whilst λ would be halved. The strength of half the field would in this case be

$$\frac{Z}{2} = \frac{P}{\frac{2\,L^1}{A^1 B^1} + \frac{2\,l}{a\,b} + 2\,\frac{1{,}440 \cdot 2\delta}{\lambda\, b}}$$

In the double horseshoe the total magnetic resistance is therefore very nearly twice as large as in the single horseshoe, and since the number of lines is halved it follows that the exciting power in both cases is equal. But in the double horseshoe this exciting power has to be applied on two magnets, whereas in the single horseshoe it has to be applied only on one magnet, the perimeters being in the ratio as 1 is to $\sqrt{2}$. The double horseshoe requires, therefore, about 40 per cent. more wire than the single horseshoe, and allowing for an equal density of current in the wire, the exciting energy will also be about 40 per cent. greater.

A double horseshoe machine has, however, the advantage of being somewhat lighter, as will easily be seen on comparing the annexed sketches. In the single horseshoe the radial thickness of pole pieces measured on the magnetic axis must be at least half that of the magnet core, so as to provide sufficient area for the flow of half the lines. In the double horseshoe no lines flow past those points, and the thickness of the pole pieces can there be reduced to a minimum consistent with mechanical strength.

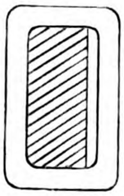


In a well-designed machine all parts ought to be equally safe as regards over heating, or, in other words, the same maximum working temperature should be reached simultaneously in field magnets and armature. It would obviously be useless to provide an armature capable of carrying the full working current for an indefinite period, if the carrying capacity of the field coils is so small that

Digitized by Google

they become dangerously hot after a few hours' run. On the other hand, however much cooling surface we might provide on the field magnets, we cannot take advantage of it if the armature has not enough cooling surface or not enough internal ventilation. From these considerations, it follows that for the armature, as well as for the field magnets, there exists a certain definite, though not necessarily the same, limit for the ratio between cooling surface and energy transformed into heat. The determination of these ratios is purely a matter of experience, and is peculiar to every type of dynamo. As a rule, field magnets arranged vertically require less cooling surface than those placed horizontally, because the heated air can more easily ascend and be replaced by fresh air. The field coils, when vertical, can also be effectively cooled on the inside by a device intended for cases where the dynamo has to work in a hot room. This device consists simply in making the internal width of the coil slightly larger than the corresponding thickness of the magnet.

In the annexed sketch the shaded portion represents the cross section through the magnet core, which is surrounded by



a rectangular coil wound on a separate sleeve. This sleeve is about half an inch wider than the thickness of the core, leaving thus an internal air shaft open at both ends. These air shafts (which are arranged on the outside of the two vertical magnets, and not on the inside, where the hot air discharged from the armature would be of little cooling value) act in a measure as chimneys, creating a gentle draft of air past the inside of the coils. It will be noticed that the waste of wire entailed by this arrangement is only about one inch per turn, an insignificant amount in large dynamos where the length of one turn in the exciting coils is a yard or more. It need hardly be mentioned that such air shafts would be useless in horizontal machines. As regards the armature, the capacity to dissipate heat depends very much on the surface speed, and on the ventilating arrangements. For dynamos working in cool places and so constructed that air is freely admitted to the armature; the cooling surface provided should be from ·8 to 1 square inch for every watt transformed into heat. By the term "cooling surface" is meant the whole surface of winding exposed to the air, both inside and outside, and the rule refers to armatures having a peripheral speed of from 2,000 to 3,000ft. per minute. Field magnet coils require from 1·5 to 1·8 square inch per watt. It should be borne in mind that these figures are only rough approximations, and may in special cases have to be considerably modified. Thus it is the author's practice to allow in dynamos intended for ship work (where the machines are often placed in hot and badly ventilated rooms) from 1·5 to 2 square inches per watt for the armature, and from 2 to 4 square inches per watt for the field coils.

The number of watts transformed into heat are calculated in the well known way by multiplying the square of the current with the resistance. Now, as regards the armature, this is simple enough, because we have to deal with one winding only, and moreover the size of the conductor is generally predetermined by the loss of E.M.F. we may choose to allow. The number of turns is also more or less a predetermined quantity (found according to our formula for E a), and therefore the investigation as to heating must be undertaken, not so much with the object of working to a definite ratio between energy lost and cooling surface, as with the object of finding whether we have sufficient cooling surface. With the field magnets the case is different. Here we can work from the outset to a definite rate of so many square inches per watt, and we can determine on this basis the amount of copper required to produce a given exciting power. How this amount of copper is to be distributed in the shape of a coiled wire (or two coiled wires in the case of a compound machine) is simply an algebraical investigation, and need not be at length described. For the purpose of making a preliminary estimate as to the amount of copper required, it is sometimes very useful to have a simple formula, which should give this as a function of the exciting power required, the energy allowed to be wasted in heat, and the dimensions of the coil. The following is such a formula :—

$$a = 7 \frac{\pi P^2 10^{-7}}{W}$$

where W represents the number of watts wasted, P the exciting power in ampere turns, π the mean perimeter of the coil, and a the aggregate cross section of all the wires in the coil in square inches. The total weight of copper in the coil is then given in pounds by the product $\cdot 32\, a\, \pi$. Knowing the shape of the section of the magnet and the length of the coil, we can, by assuming a certain thickness of winding, calculate, in the first instance, an approximate value for the cooling surface. This, combined with the predetermined ratio of square inches per watt, gives the total number of watts W which can safely be transformed into heat. The value of a can then be calculated and the winding determined. If its thickness should greatly differ from that first assumed, a new value for W must be calculated and taken as the basis for the final determination of a.

TELPHERAGE.*

BY PROF. JOHN PERRY, F.R.S.

(Concluded from page 326.)

From my preparatory lecture you will understand that when the motor is running at its normal speed of 1,700 revolutions per minute, requiring, say, a current of eight amperes, the speed is diminished on account of the train going up hill. The motor will receive a greater current from the engine house, and this means that in going at a slower speed it is able to exert a much greater effort; and we find that the train diminishes its speed only a very little when it finds that an extra effort is required sufficient to draw it up an incline of 1 to 13. The fall of potential along the telpher line, of which I spoke to you in my last lecture, and which is so very serious in electric lighting, was feared by us at first, as it was probable that trains near the engine house would move much faster than trains which were farther away. But we have got over this difficulty by an electrical governer, a most ingenious contrivance of Prof. Jenkin's, which is attached to each locomotive. You will understand the construction of this governor from Fig. 23.

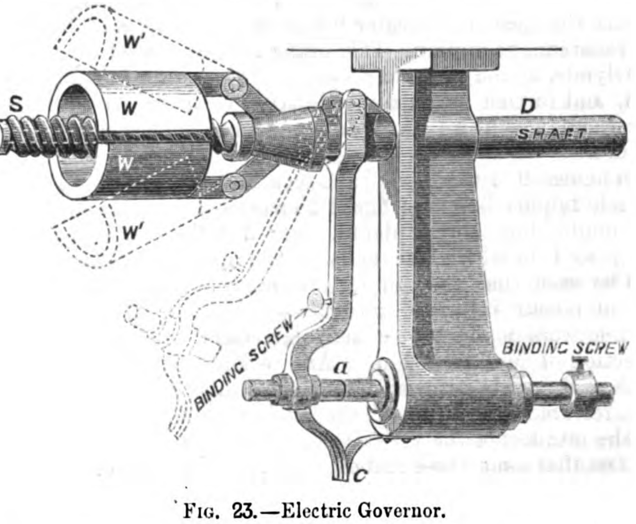


FIG. 23.—Electric Governor.

D is the second shaft and W W the two weights of a centrifugal governor, which are held in positions near the axis by means of

* Lecture delivered at the London Institution, 28th January.

Digitized by Google

the spring S. When the masses W W fly apart into position W′ W′, they draw the lever into the dotted position and break the metallic contact at *c*, so that no electricity can be received by the motor. The weights of the governor are so hung that if, for example, they fly out against the pressure of the spring at a speed of 1,700 revolutions, they fly out very far, and the break at *c* is performed very rapidly. But no spark occurs at *c*, because after the contact is broken there, there is a contact maintained for a short time between two carbons at *a*, or a piece of carbon and a piece of iron, one of which is compelled by a spring concealed in the frame to follow the other for some distance. If the contact be suddenly broken when the motor is making 1,700 revolutions per minute, contact will not be restored again until the speed of the motor has become reduced to about 1,500 revolutions per minute, so that the electric current is cut off during this interval. Whatever, then, be the potential difference at the terminals of the motor the governor keeps the motor running at a speed of between 1,500 and 1,700 revolutions per minute. But inasmuch as going down steep inclines the train has power to propel itself without receiving any electricity, we have also placed on one of the shafts A A the brake shown in Fig. 24, where W B, W B

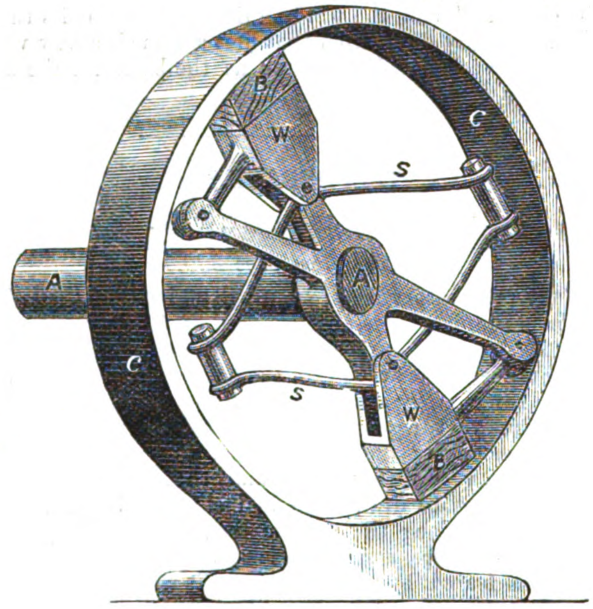

Fig. 24.—Mechanical Brake.

are two weights whose centrifugal force up to a certain speed is balanced by the springs S S; but above that speed, which corresponds to about 1,800 revolutions of the motor, the wooden brake-blocks B, B press against a fixed metal ring C, the greater the speed the greater being this pressure, and therefore the resistance to motion. This brake is rarely called into action at Glynde, as the electric governor performs its function very well, and further renders any description of the other electric governors which we have designed also unnecessary in this lecture.

In figures 9, 10, 11, you have seen the posts employed in the Glynde telpher line, and figure 25 shows the usual support for this double line more in detail. At A A the cast iron saddles are placed to which the ends of the rods are fastened It will be seen that the supports require only a very unskilled sort of labour in their construction; indeed, all the posts at Glynde were made by common labourers working under the direction of Mr. Anderson. And when the Honourable Mr. Arthur Brand, in his speech on the opening day of the Glynde line, referred to the marvellous quickening power of electricity on the intellect of the agricultural labourer, he was referring to the fact that some Sussex labourers had become skilled workmen during the erection of the line.

The depth to which the supports must be sunk in the ground depends on the nature of the soil. At Glynde they are sunk to a depth of from four to five feet, and each of them has a worn out railway sleeper placed underneath it. In harder ground the sleeper would not be used, nor should we sink the supports to such a great depth. In many parts of India or Egypt we should probably have the part of the support which enters the ground made of metal; but indeed these supports, having to carry as they do only very small loads, may be constructed in many different ways, depending on the materials to be found in the district where a telpher line is to be erected. At first the saddles placed on the support were made so that they could rock slightly; but we now find that it is better to fasten them rigidly to the post, the post itself yielding sufficiently.

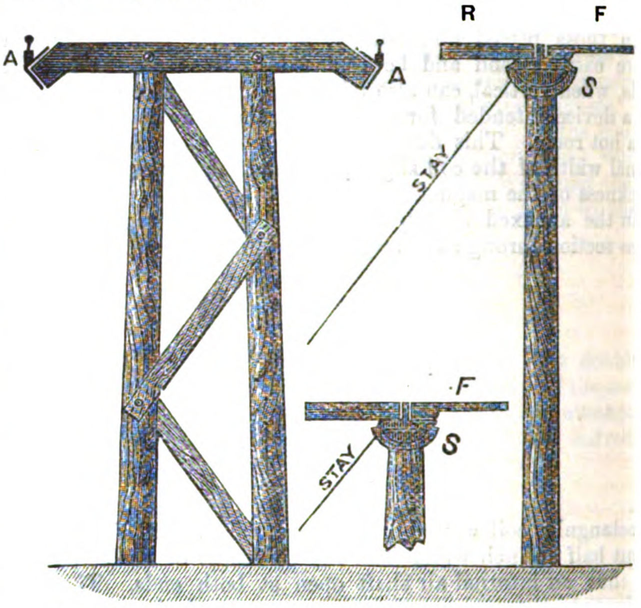

Fig. 25.—Ordinary Post. Fig. 26.—Abutment Post.

Fig. 26 shows what we call an Abutment Post, of which there may be one at the end of each curve. The saddle S

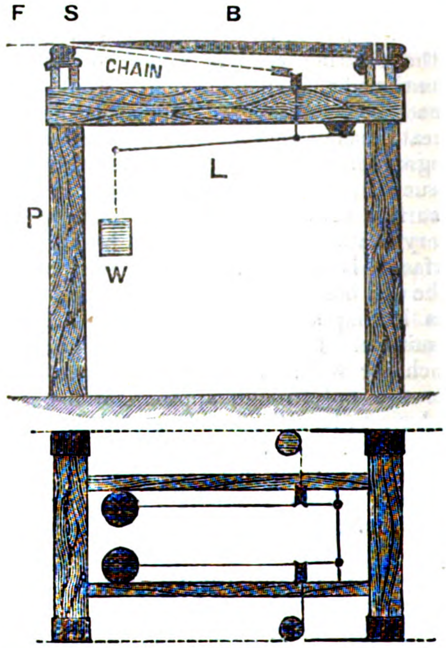

Fig. 27.—Elevation and Plan of Compensating Gear.

carries on the one side the end of the flexible rod F, used along the greater part of the line, and on the other side the end of the stiff rail R, which (as seen in Fig. 12) is employed along the curves. The abutment post is anchored back into the ground by these two tie-rods, which may be shortened or lengthened by turning these nuts; and these stays enable us to give any tension we please to the rods of the line. At different points of the line we place what is called a *Compensation Gear*, shown in elevation and in plan in Fig. 27. In this the post P may be regarded as an abutment post, by means of

Digitized by Google

which we can alter the tension in the line to the left. But it will be seen that the flexible rod F is not fastened to a saddle at the top of the post P, but is fastened to a chain which is pulled by means of a lever, L, and a weight, W, so that the tension in the rod F is maintained as nearly as possible at 2¼ tons. Should the tension at F be greater than 2¼ tons, the lever rises, letting the rod F slip over the little saddle S. This compensation gear then causes the tension of the rod F to remain at about 2¼ tons, however many trains may be on the line, and whatever may be the temperature. The stiff blade B is made of steel, and rests on F in such a way that a train can readily pass from F to B or from B to F, and yet F has freedom to move on the saddle when the tension varies. At Glynde we have four such compensation gears, but experience shows that two of them per mile are all that are required, and this smaller number we propose employing in the next telpher line.

For future telpher lines I hope that it may be possible to obtain the 66 foot lengths of flexible rod in complete lengths from the manufacturer. The flexible rods at Glynde, made of ¾in. basic steel, have each at least three welds in them. I have heard that some complaints have recently been made as to the behaviour of basic steel; but I wish to say that the behaviour of this steel in the rods at Glynde has been marvellously good. The rods as originally designed came in two lengths, each with a forged end, and the two lengths were welded together at Glynde to make one rod. After the erection of the line it was found that although each of the rods before it was erected had withstood a severe test in a specially constructed testing machine, yet in the actual work of the line seven or eight fractures occurred in the forged ends in about two weeks All the rods were therefore taken down, the forged ends cut off, and pieces of round rods put on with their ends turned down as you see in the diagram, and not one single case of fracture has occurred since that time, nor has any rod been fractured at a place where a weld was made in a field at Glynde. That three welds should be made in each of 130 rods of basic steel so carefully that not one of them has broken during the last three months of constant work, despite the great loads to which they are subjected, shows that the smith, whose name is Hindell, and who came from Middlesborough, performed his work with an amount of faithfulness which may be regarded as wonderful in these days. In future, however, telpher rods will be made without any welds. These long rods may be sent in a rolled up condition, or bent at one or more places, depending on the distances to which they may require to be carried from the steel manufactory.

Although the survey and levelling of the line had been only roughly performed—and, indeed, at one place we found ourselves some four feet wrong in the heights of the posts—yet I had no difficulty in fixing the lengths of the rods to just give the tension wanted everywhere in the line. This ease in construction was greatly due to the yielding of the posts and to our having abutment posts and compensation gear.

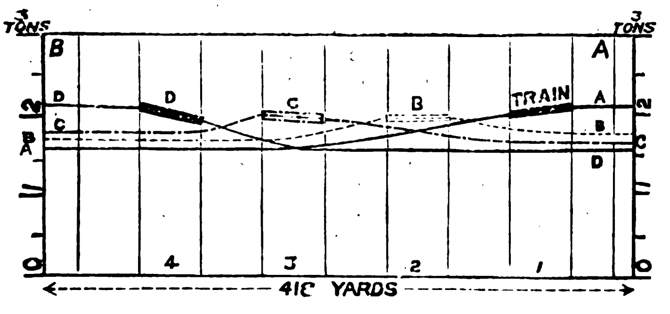

FIG. 28.—Diagram of the Tensions in the Line.

In Fig. 28, curve A A A shows what is the tension at every part of a section of a line when the train, which covers two spans, or 132ft., is at 1, vertical distances representing the tension in tons in accordance with the scale shown at the side. Curve B B B shows what the tension is at every part of the line when the train is at 2

Curve C C C when the train is at 3.
„ D D D „ „ 4.

In this particular section of the Glynde line the compensation gear, which was placed at the end B, had just been erected, before the measurements were made whose results are shown on the diagram, so that all its joints were stiff, and it, therefore, did not maintain so constant a tension at its end of the line as it did a little later. It will be seen, however, that the tension in a rod is greatest towards the two ends of a section when a train is approaching either of those ends. In making a measurement of the tension in a rod at any instant, unless a loaded train is on the rod, the measurement was at first very difficult, and I thought that I should find it necessary to design a complicated instrument to do this, as it was absolutely necessary to make such measurements for the adjustment of the line. I discovered, however, that I could use what may be called a *fiddle-string test*, depending on the fact that when the rod is allowed to vibrate, it vibrates more quickly the greater the tension in it. I found that some of the labourers could be trusted to measure the tension in any of the rods by setting the rods swinging, and by measuring the number of the vibrations made by the rod in ¼min. Twenty-five vibrations meant that there was a pull of 1 ton,

30 vibrations that there was a pull of 1·44 ton.
35 „ „ „ 1·96 „
37 „ „ „ 2·25 „

We have taken pains that in the usual working no rod in the whole line, no matter where the train may be, shall have greater tension in it than 2¼ tons, and this allows for a considerable factor of safety, as we have tested the line with much greater loads than this.

To make permanent electrical connection between the steel rods at the cross-overs (see Fig. 8) has proved to be a matter of considerable difficulty, and the method which I have adopted at Glynde, although it is successful, is one which I am not particularly proud of, and I feel sure that some simpler method may be adopted in future. We have bored a slightly tapering hole through a part of the steel rod where it is not much strained, and driven in a plug of copper, which is sufficiently long to have a thick copper wire soldered to it on the outside, and to have a head riveted on the smaller end. At first we brazed these plugs of copper into the steel rod, but subsequently they were only riveted in.

I think that I have now mentioned most of the details of the flexible parts of the line. It only remains to say that at sharp curves, and at the two ends of the line, we find it convenient to use, instead of flexible rod, a stiff bulb angle iron, as seen in Fig. 12. This rail of angle iron is supported by posts 13ft. apart, and the bulb angle iron rests on the wood directly, or else on an insulator attached to it at the post. Both plans are in use at Glynde; but we have found that the insulator may be dispensed with. When, however, at every fifth post the new section occurs, which must be insulated from the former, and where, therefore, the end of the rail on one section must be insulated from the end of the rail near it belonging to the other section, we use an insulator and a saddle somewhat of the shape of the insulator and saddle shown in Fig. 14. In one place where a brook has to be bridged, instead of placing these posts at 13ft. apart, they are placed at 26ft. apart, a supplementary angle iron being riveted underneath the usual two lengths to give the necessary strength.

A very effective form of siding was tested at Weston, and found to answer. It consists of a hinged stiff blade of steel, which connects a stiff siding with the main line at any place when it is lowered down so as to rest on the line. Sidings of this kind will be introduced at Glynde, should they be found necessary, after a while. In concluding this description of details, I may say that it would now be possible for the staff of the Telpherage Company to order material, to examine this material before it left the factory, and to erect a line of any length of the Glynde type in such a way that no hitch of any kind would be found to occur in the erection, and that not one bolt too few or too many would be sent from the manufactory, and that the line would work perfectly on first being

Digitized by Google

tried. We know to a great nicety the cost of the materials, and of the erection of telpher lines. We are more doubtful as to the cost of steam power, and of wages; but using the highest figures likely to be taken by any critic for steam power and wages, I find that the total cost of a telpher line whose length is x miles of double track, and which carries y tons of material per annum in one direction, the skeps coming back empty, is expressed in pounds sterling by

$$275 + 350x + \cdot 027\,xy,$$

and the working expenses in pence per ton-mile of material carried by

$$\frac{46,800}{x \times y} + \frac{23,184}{y} + 1 \cdot 85,$$

fifteen per cent. per annum on the capital expended being included for interest and depreciation. Thus, for example, to carry 84,000 tons per annum—which is the limit of carrying power which I should advise for a telpher line like the one at Glynde, as it places the trains six spans apart—the cost per ton-mile is $2\frac{3}{4}$d. if the line is only one mile long, and it is only $2\frac{1}{4}$d. if the line is ten miles long. To carry 42,000 tons per annum 10 miles the cost is $2\frac{1}{2}$d. per ton-mile, but if the line is only one mile long the cost is $3\frac{1}{2}$d. In fact, it may be said that on a railway the carriage of goods may be done at the rate of about 1d. per ton-mile if there is a sufficient amount of traffic; that on a telpher line the cost is from $2\frac{1}{4}$d. per ton-mile upwards, in many probable cases being from 3d. to $3\frac{1}{2}$d.; whereas cartage cannot be performed at much less than 1s. per ton-mile, and in even at this much higher price the cost of constructing the cart-road and keeping it in repair is left out of the account.

And now that you have had a description of the telpher line at Glynde, and seen the slides taken from the photographs of the line, you will understand the significance of this quotation from an article in *Nature* of last November.

"On Saturday, Oct. 17, a special train from Victoria conveyed a party of about 200 guests, among whom were many leading electricians, engineers, and other well-known men of science, to Glynde, in Sussex, to witness the ceremony of the opening of the first telpher line erected in this country. The ceremony was performed by the Viscountess Hampden, and was of an exceedingly simple character. On lifting a small box, containing a present which the Chairman of the Company invited her ladyship to accept, electric communication was instantly established between the dynamo in the engine house, and the telpher line, and a garlanded train loaded with clay at once began to move up an incline towards the Glynde Railway Station, amidst the applause of the assembled spectators. Whether this ceremony, which brought so many distinguished visitors down to Lord Hampden's estate on Saturday is the inauguration of a great commercial enterprise is beyond our province to inquire, but it is unquestionable that the slight flash seen when Lady Hampden lifted the little box lying on the table in front of the engine house marked the beginning of a new departure in electro-technology."

When a telpher train is first seen running it is very difficult to understand its method of propulsion. The train's flexibility as it moves along the line at $4\frac{1}{2}$ to 5 miles per hour, and the unlikeness of telpherage to any other method of propulsion, the train appearing to be a long living thing of the snake species, are so remarkable that when it is announced to be a method of electrical propulsion, it is probable that the electrical engineer is at first more astonished at it and more unable to comprehend its action than anyone else. An empty train at Glynde will travel to the clay field, where it sinks down nearly to the level of the ground; the labourer touches a key and so stops it; the skeps are filled with clay, the key is touched again, and the train starts off round the stiff rail in the clay field, soon getting to the flexible part of the line again, and steadily wending its way to the railway siding, where, without stopping, it drops its loads into the railway waggons. It then passes round the stiff rail end in sight of the railway bridge, and travels steadily back to the clay field, all the time—whether loaded or empty, whether going up hill or down hill—travelling at the same speed of about $4\frac{1}{2}$ miles per hour. It was unfortunate that only one river had to be crossed (seen in Fig. 10), since had there been more the advantages of telpherage would have been even more exemplified. Sometimes, however, during the winter, some of the fields over which it passes are several feet deep in water, and if repairs had to be effected it would be necessary for the men to go in boats or rafts to the line, so that on the whole it passes over a fairly watery country. Looking at the ground it is very difficult to see how it would have been possible to carry this clay in any other manner than by telpherage, without building a very expensive road with a bridge over the river to the railway station. I am happy to say that the telpher line was erected while cattle were grazing in the field over which we run, and that the compensation for damage done which we were required to pay, and which was principally due to some of our workmen taking short cuts across fields instead of the regular paths, amounted in all to only £25.

It must be remembered, too, that if a turnip cutter or a shearing machine, or a thrashing machine, a winnowing machine or a plough, or any other agricultural tool, requires to be worked, it can be driven by attaching an electro-motor to one of these supports and connecting it by means of two little wires with the rods at the top of the posts. Thus, on the exhibition day at Glynde, a turnip cutter was being driven from the line by means of this very little motor which you see on the table, without interfering with the regular working of the trains. Now it must be borne in mind that the capital cost of the line itself, or permanent way, is a comparatively small part of the cost in telpherage, and that, in reality, the expense is in the trains and in the dynamo machines which drive them. Now, suppose that such a line as the Glynde line of 1 mile long is built, and we start with 3 trains, each train will carry 6,000 tons in one direction in one year; but should it be required that instead of carrying 18,000 tons per year the line should carry 24,000, or any other number of tons per year, it is only necessary to add the required number of trains, and if the dynamo machine already existing is not sufficient a new one has to be added. In fact, it is a system in which the capital cost will increase in a proportion which is not very far from being that at which the work to be done is increased. It is to be remembered that we can pass over gorges in mountains and up and down steep inclines over very uneven ground, that there is no difficulty in going round even very sharp curves, such as introduce enormous wear and tear and friction in the wire rope haulage system; and that, although I have told you of weights, each of which was less than 3cwt., yet we can design lines, especially when we use stiff rails, to carry almost as much as we please. Our source of power may be near the line and preferably near the middle of the line; it may be a steam engine or a water wheel, or it may be placed at several miles from the line.

The inquiries which have come to us about telpher lines show that it may be used in many more ways than those of which we thought at the beginning. As we have it at present, it will not only be very useful in bringing ore from mines, but it is easy to arrange for a telpher line which will load or unload a vessel which is unable to come close to shore on account of the shallowness of the water, and we can imagine these trains of skeps running out over the sea, running down into the hold of a vessel, running up again, and coming back to land.

The immediate application of telpherage is not, I think, very likely to occur in a country like England, where the common roads and railways and tramways are already so numerous that telpherage can only be worked probably for short distances to feed the railways. But consider a country which has few roads and railways, a country like Japan, a country teeming with population, where, excepting in the neighbourhood of the treaty-ports, the roads are not much better than bridle paths, where the only method of conveying goods is on the backs of the coolies or on pack-horses. The price of rice and other materials is vastly different at a seaport in Japan where the steamers call from what it is in the middle of the country, and when we consider the small load that a pack-horse will carry on its back, and the price which must be paid per mile, it will be seen that a system of telpherage, by which goods would be

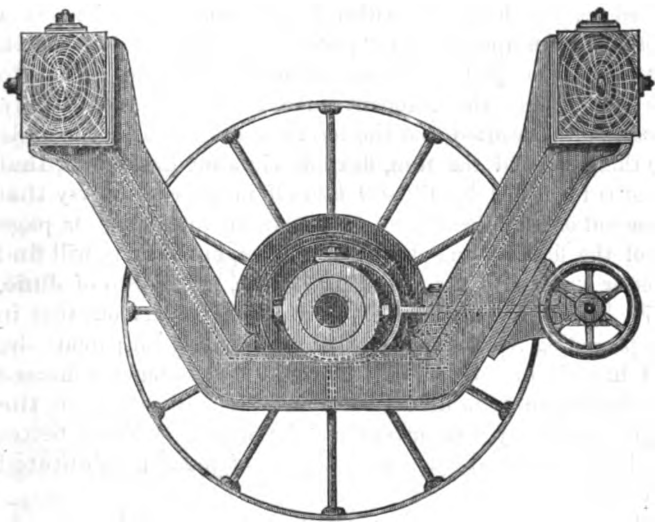
Digitized by Google

carried at from 2d. to 4d. per mile, or at cheaper rates if worked by waterfalls instead of steam engines, would lead to the development of a country which did not possess capital enough to build railways or even to make common roads. Military men have told us that the use of a telpher line would be nearly invaluable in bringing stores up to the front in a military expedition, and, indeed, when at an evening party, at my own house, about a year ago, this model which you see before you was exhibited to my guests, some of them told me that it saddened them to think that telpherage had not been sufficiently developed before that time for the crossing of the desert from Souakim to Berber.

We have at present very modest aims. I should prefer for some time to simply develop lines like the one at Glynde; but I am quite sure that in future, when more capital than we have had at our command is employed to develop the system, we shall have trains of skeps passing down empty into coal mines and along the workings, to be filled by the men as they dig the coal from the face, come back to the bottom of the pit, and, moving up a vertical rod, pass on to the ordinary lines at the surface, and without stopping, except, perhaps, to be labelled, travel along, shunted from point to point by men properly stationed, who will know what to do with each train by seeing the ticket stuck upon it, and will eventually reach the door of the customer who is to use the coal. The immense amount of worry which there has been in the development of telpherage, even as we now see it, shows me that its grandest developments cannot come in my own time, but that it must come in the long run, and that telpherage will be a general system of distribution of goods is a fact which is fixed in my mind so securely that no amount of disappointment or worry can remove it.

ELECTRIC LIGHTING AT MANCHESTER.

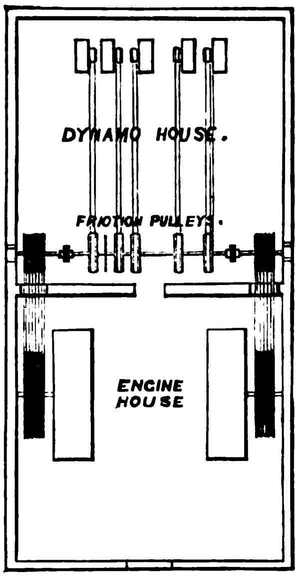
The large buildings recently erected by the Lancashire and Yorkshire Railway Company for their new offices at Hunt's Bank, Manchester, are fitted throughout with the electric light. The generating station is situate at the back, near to, and below the bed of, the River Irwell, where excavations were made for the necessary accommodation. A couple of locomotives have been renovated and transformed into a capital type of semi-portable engine, each being supplied with fly-wheel grooved for eight ropes, and arranged so that the machinery may be driven from either engine.



End View—Countershaft and Hangers.

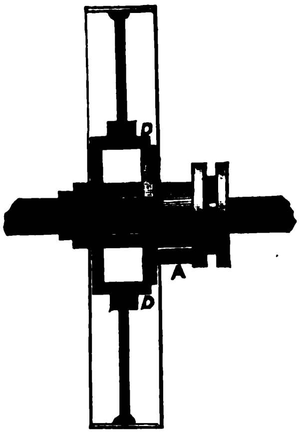
The counter-shaft, 3¾in. diameter, spans the dynamo house and revolves at 350 turns per minute in self-lubricating pedestals suspended by hangers from polished pitch pine beams overhead.

Four dynamos are employed in charging accumulators for passenger trains and for the lighting of the offices. By the use of Bagshaw-Addyman friction pulleys, as shown, any machine may be stopped or started whilst in motion without moving the belt and without shock. These pulleys are bushed with phosphor bronze, and are each capable of transmitting 40



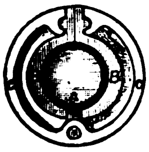
Plan, Electric Light Installation, L. and Y. Railway.

indicated horse-power. They are instantly connected or disconnected by the simple insertion or withdrawal of a wedge,



Longitudinal Section—Friction Pulley.

operated by a hand lever. When running at full speed with all power on, everything keeps cool and works smoothly, evidence



Transverse Section.

of good work and perfect balance. In the transverse section B B shows the levers opened out by the pin A, thereby expanding the friction ring C.

Societe Internationale des Electriciens.—Owing to the great increase in the number of members of the International Society of Electricians of Paris residing in England, the Council of the Society have appointed one of their members, Mr. R. Aylmer, M.I.C.E., A.S.T.E., of 42, Parliament-street, S.W., as hon. secretary and treasurer for Great Britain.

ANSWER TO CORRESPONDENT.

T. BILHAM.—*The results depend upon the conditions. If the person is well insulated we doubt if there is any danger in touching the wires with one hand with the usual machines. The person may, if not well insulated, form part of a shunt circuit, and contact, even with one hand, may be dangerous.*

THE BASSANO TELEPHONE JUDGMENT.

The decision in the case of the UNITED TELEPHONE COMPANY *v.* BASSANO was given so far back as last August. Mr. Justice NORTH, therefore, cannot be accused of haste in the preparation of the elaborate and formal judgment he has just delivered, and which we print in another part of this paper. The first thing that strikes an impartial observer about this judgment is the absence of any attempt to find out what the patentee, whose specification was the subject of the alleged infringement, meant by the terms he used. The patentee in question was Mr. EDISON; the specification was that relating to his "instrument for transmitting electric impulses by sound," since re-christened "the carbon telephone," the alleged infringement being the well-known apparatus of BASSANO and SLATER, having pencil microphones of hard electric light carbon placed across the bottom of a conical wooden tube, which rested in a socket attached to a back board of red wood.

EDISON'S specification above referred to is a very remarkable document. The instruments described and claimed by it are nowhere called "carbon telephones"; they are not denominated "telephones" at all, that term being reserved for the receiver; nor is the substance "carbon" ever once mentioned from first to last. Of the thirty claims which originally accompanied the specification, twenty-nine have since been struck out, leaving one claim only, and that one limited by a significant disclaiming clause preceding it. The surviving claim runs thus:—"I claim, in an instrument for transmitting electric impulses by sound, the combination with a diaphragm or tympan of electric tension-regulators substantially as hereinbefore described for varying the resistance in a closed circuit, substantially as set forth." The preceding clause runs thus:—"I will observe, in conclusion, that I do not claim generally the transmission and reproduction of sounds by increasing and decreasing the resistance of the circuit, nor do I claim separately any of the parts or arrangements hereinbefore described and illustrated in the accompanying drawings, except as hereinafter mentioned."

Now, with this emphatic disclaimer both of general principle and of separate details before him, limiting the claim solely to the combination of one detail with another detail of the instrument, the learned judge would naturally be expected to inquire most carefully into the actual meaning intended by the patentee to attach to the terms in which he described the two essential elements of his combination. And it should have been, at least in one respect, an easy matter to decide this point. The prior history of telephony would have helped; and EDISON'S own letters of 1878, in the famous HUGHES-EDISON controversy, would have made clear the meaning he attached to his own words. The terms "diaphragm or tympan," used as synonyms by EDISON for one of the two essential elements, are sufficiently explained in the text of the specification. The tympan was to be "like a drum." It must be—to judge by the numerous drawings—a real drum-head, circular, flat, thin, attached at the edges, bending under the influence of the voice, and if not made, as recommended, of mica, must at least be flexible like mica. The history of telephony would have revealed successively the parchment drum-head of the "lovers' telegraph," the membranous diaphragm used by REIS in imitation of the ear, the goldbeaters' skin diaphragm of GRAHAM BELL'S earlier, and the thin iron diaphragm of his later instruments.

All these were well-known prior to EDISON'S patent. EDISON nowhere hints that his diaphragm or tympan was anything more than these. He mentions, indeed, in one place, another kind of mechanism to be placed inside a speaking tube, a metal plate clamped rigidly near its centre, and free to vibrate at its edges, but he never called it a "diaphragm;" he put a separate claim upon it as a "plate;" and then, later, struck out the claim, just as he struck out the claim for adding to the instrument the resonant tube or mouthpiece. Were further proof wanted that the term diaphragm did not include anything beyond the thin, flexible, vibrating drum head, that proof is furnished by EDISON himself in the controversy that arose out of the invention of HUGHES'S microphone. On page 70 of the first volume of *The Electrician*, our readers will find a letter written to the *New York Tribune*, on the 8th of June, 1878, by Mr. EDISON himself, in which he points out that in the preceding April—ten months after his English patent—he had himself discovered that he could with advantage discard the diaphragm from his instrument. "The discarding of the diaphragm is my own invention," he wrote. "Much better results are obtained when a rigid plate of metal is substituted in its place."

Mr. Justice NORTH has apparently proceeded on very different lines to find a meaning for EDISON'S terms. Oblivious of all the work done by GRAHAM BELL, and before him by REIS, he declares EDISON to be the original inventor of the speaking telephone, and as such entitled to have the widest interpretation put upon his language. EDISON said that he might have one or more diaphragms at the ends or sides of the resonant chamber, and they might be of different sizes; Mr. Justice NORTH forthwith decides that anything at the sides or

Digitized by Google

ends of the chamber is a diaphragm! Even a microphone pencil is a diaphragm. The doctrine of "benevolent construction" could hardly be stretched beyond this. Even if it were true that EDISON was the first to construct an electric speaking telephone, any grounds for benevolent construction—or, in other words, judicially giving to an inventor more than he has claimed, or is entitled to—would be effectually disposed of by EDISON'S own disclaimer of general principles. The man who, in order to outrival GRAHAM BELL, was instructed—as he himself has stated on oath—by his employers, the Western Union Telegraph Company, to remodel REIS'S telephone, is now held up as the original inventor, and *therefore* everything is to be benevolently strained in his favour.

This decision is the more regretable, we think, because it is the triumph of a wealthy monopoly over a poor inventor. Mr. BASSANO is known and respected as a modest and hard-working telegraph engineer. He had, it is plain, honestly imagined that when EDISON said "diaphragm" he meant "diaphragm," and did not mean a "tube" or a "pencil," or anything but a "diaphragm." He is now made the victim of a judicial pronouncement which has so strained the definition of a diaphragm as to make it include all of these things. Mr. BASSANO has been unfortunate throughout in this action. Of the two eminent counsel whom he sought to retain to defend him, one was unable to take up his brief; the other deserted the case to go on circuit. Against him he had the ablest of counsel and the most eminent of experts. These gentlemen went through the solemn performance of tying the two ends of a string to two conical wooden tubes, into one of which they talked, while their words were heard at the other, as in the old lovers' telegraph. Upon this they founded the following amazing syllogism:—If you talk to a diaphragm it vibrates; if you talk to a tube it vibrates; therefore a tube *is* a diaphragm. Mr. Justice NORTH calls this a most conclusive experiment, decides that a tube is a diaphragm, and Mr. BASSANO has to pay the costs. Mr. Justice NORTH, indeed, went further. Everything is a diaphragm if the air-pressure on one of its sides is different from that on the other. That is the newest legal definition of a diaphragm, and it will include everything, from a flying bird to a burning candle. We are of course unable to accept this as a scientific definition, and we regret it as a legal deliverance on public grounds, partly because it was obtained by a rich and powerful monopoly, and partly because it will tend to establish that monopoly more firmly than ever.

CORRESPONDENCE.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A fortnight ago the writer to whom I had replied recanted the first of his mistakes, viz., the use of 736 instead of 746 as the number of watts in the horse-power. This week he so far relaxes on the second point as to condescend to say that he prefers to call "the proper working speed" that which I and others had consistently been calling "the critical speed;" and I perceive that he no longer insists that a dynamo that is only partially self-excited cannot have a critical, *i.e.*, a proper working speed. This being so, my aim in addressing you has been attained. But the writer goes further and now attacks the theory of the self-regulating motor, a matter which is outside the two points of correction about which I wrote. His doubts as to the correctness of the theory in general come a little late in the day, inasmuch as the theory and the equations of the self-regulating motor were propounded so far back as 1883 by my friends Profs. Ayrton and Perry.—Yours, &c.,

SILVANUS P. THOMPSON.

Finsbury Technical College, 29th March, 1886.

THE DIGNITY OF SCIENTIFIC DISCUSSION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is high time that a word of warning should be spoken against a growing tendency lowering to the tone and character of discussion in the Society of Telegraph-Engineers and Electricians. The society holds its meetings in the theatre of the Institution of Civil Engineers, and a comparison between the proceedings of the two learned bodies naturally suggests itself. Comparisons are proverbially odious, but they may at times be also very instructive, and I venture to assert that the Telegraph Engineers have as a body a great deal to learn from the Civil Engineers in the matter of carrying on discussions with that decorum and courtesy which should be a kind of second nature with any assembly of scientific gentlemen. A few weeks ago the members were treated to the spectacle of two learned professors wrangling with and contradicting each other across the President's chair; and only at the last meeting a person got up, in spite of the announcement by the President that the discussion was closed, and persisted in addressing the meeting in a manner which resembled very much the touting of a cheap jack at a market fair. Of course, his remarks were greeted with roars of laughter by the audience; but, apart from their humorous aspect, such exhibitions have a reverse side which is painful and humiliating. No electrician who has the welfare of his society at heart can see with indifference the authority of the Chair set aside, and the effect of attempts to do so is distinctly demoralising. That this is the inevitable result was immediately made apparent, for when the President announced that the discussion would be continued at the next meeting one of the members, who is generally well known for his courtesy and tact, took it upon himself to direct the attention of the President to the question whether the author of the paper should at once reply to the discussion as far as it had gone, or should reserve his reply till the whole of the discussion had been completed. Can anybody imagine such a breach of etiquette to happen at the Civil Engineers'? I think not.

The existing state of affairs is not chargeable to the present President, for the evil has developed under successive presidents, and I remember one presidential address, some years ago, which, from its nature, was not open nor intended for discussion, being severely criticised by the very member of council who got up to move the customary vote of thanks. A president cannot be continually calling speakers to the point. Neither can he, as a rule, cut short any speaker who might dwell unduly on points of theory instead of bringing forward practical experience. Two hours every fortnight is a very short time in which to transact business, read papers and discuss them, and to save as much time as possible the order of speakers seems to be generally settled beforehand. The first speakers thus have practically *carte blanche* as to time, and generally abuse the privilege, so that subsequent speakers, although on the list, must compress their remarks too much to be of value, and those amongst the audience who have not had an opportunity of sending in their names are often debarred from speaking at all. This in itself is an evil, but it it is not all. The speech of inordinate length is almost sure to contain irrelevant matter, and if that be the case the temptation to criticise the discussion of the paper, instead of the paper itself, becomes very strong. The result is that previous speakers are in their turn tempted to interrupt the proceedings by defending their remarks or by explaining what they meant. All this could be avoided if every speaker would bear in mind that it is his duty to assist the president in making the discussion as good as possible, not only by the relevancy and scientific or practical value of his own remarks, but also by sitting down at the right moment.—Yours, &c.,

SECONDARY BATTERY INDICATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : No reply having appeared to Mr. Elwell's letter on the above subject in your issue of the 19th March, I venture to say with reference to the suggested difficulty of maintaining the electrolyte at a constant level, that this is not a very difficult matter to ensure within practical limits on the part of the attendant by the ordinary means of filling up the cells with water to the proper mark as it evaporates; but, if desired to effect it with exactitude automatically, a simple method, which I know to have been adopted by Mr. Sellon, is to use an inverted flask or vessel, which, as occasion requires, is refilled with water and placed with its neck, or outlet tube, at the level which should be maintained. Displacement, of course, takes place in the vessel, and compensates for the loss by evaporation or other cause. One of the main objects of employing indicators is to prolong the life of the plates by ensuring proper limits of charge and discharge. It may be well, therefore, to consider the action of the apparatus described by Mr. Elwell relatively with Mr. Sellon's arrangement, described in your issue of March 12th.

In the first case, viz., Mr. Parker's device, which he states is not affected by alteration in the level of the electrolyte. By evaporation of water the solution becomes higher in density, and as a result his appartus cuts the cells out of the charging circuit *before they are fully charged*, allowing them also to remain in circuit *until they are overdischarged.*

In the second case, supposing no compensation is made as arranged for by Mr. Sellon, the increased density through evaporation of water would cause the apparatus to bring the cells into the charging circuit *before they were fully discharged*, also to allow them to remain in circuit until they were *slightly overcharged*—certainly the preferable alternative for keeping the cell in good working order. But, as I have already said, the maintenance of a constant level presents no difficulty, and no such variations need occur.—Yours, &c.,

March 29, 1886. HENRY A. KENT.

MISTAKES IN ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much obliged to Mr. von Tunzelmann for his answer to my inquiry. It is the best and clearest answer I have got from any of those parties who believe in that which is called the theory of two electricities.

Mr. von Tunzelmann maintains that electricity is neither matter, nor force, nor energy. When two pith balls are electrified positively, they move from one another. According to Mr. von Tunzelmann's writings to you this event takes place according to "the law of electrical repulsion." Will Mr. von Tunzelmann be so good as to state wherein the repulsion resides ?

Again, when the two pith balls are electrified negatively they move from one another according to the same law of repulsion. Will Mr. von Tunzelmann state wherein the repulsion resides in this case also ?—Yours, &c.,

JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, 27th March, 1886.

THE ELECTRIC LIGHT AT MUNCASTER CASTLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In your notice of our installation of the electric light at Muncaster Castle in last week's number of *The Electrician*, you draw attention to some points respecting the positions of the lights in the rooms which we should like to offer some explanations upon. Owing to the Castle being in the hands of decorators and builders your representative did not see things quite in their usual state. The pillars which you mention in the hall or saloon are provided with large silk shades, which were then carefully stowed away and invisible, and they are not intended to light the room generally, but to be used as reading lamps to throw light upon lounges which stand under these pillar lights. We quite agree with your remarks respecting the dining room, and should have preferred to light this as we have lighted many similar dining rooms, from the ceiling, but a preference was expressed in favour of the older method of illumination by wax candles.

We do not think any advantage is gained by silvering the upper half of lamps placed over the billiard table. The lamps when in use are covered by the usual large paper shades, and these throw down the light in a more satisfactory manner than can be obtained by silvering the lamps. The latter method causes too much shadow to be thrown upon the cloth by the balls. We have tried many ways of lighting billiard tables, but have never found anything answer so well as the ordinary large paper shades, which require to be placed at exactly the correct height from the cloth to give an even light upon every portion of the table.—Yours, &c., J. EDMUNDSON AND CO.

19, Great George-street, Westminster, March, 31.

ARMATURE RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Will one of your able contributors kindly put me right on the following matter ? The resistance of an armature when running, and without reckoning the increased resistance due to heating, is usually reckoned at half the resistance of total length on armature, because the current divides at the negative brush and traverses each half, meeting at the positive. It appears to me that the resistance should be only one quarter, because virtually the two halves of the armature coils are in multiple or shunt. Suppose the bottom half of armature taken away, the current then would only have one path to traverse, and this being half the length of wire on the whole armature, will, consequently, be half the resistance; then adding the bottom half will open another path to the current of the same section and length as the upper, which reduces the whole running resistance to one quarter of the measured resistance of total length on A. If I am wrong in my reasoning I shall esteem it a favour if one more able than I will point out my error.—Yours, &c., DYNE-AMICABLE.

ELECTRIC LIGHTING AT THE LAW COURTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You will doubtless have seen paragraphs *re* the electric lighting at the Law Courts. Do you not think that the reporter who made the statement that the *screw passing through the top of the glass was too fine* has in some way got muddled ? I can scarcely credit that any electric engineer, let alone one entrusted with an installation like the Law Courts, should make such a statement. Consequently, if the reporter made a mistake of that kind I think others of his statements as to rheumatism, bronchitis, catarrh, &c., are equally misleading. At any rate, if the daily press wants to insert the reports of its correspondents, should it not assure itself by expert evidence that they have at least the *possibility* of being correct ?—Yours, &c., FAIRPLAY.

London, March 31, 1886.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 296.)

*General Considerations on these Theories.**

We shall now go on to discuss a general way of treating theories of the kind we have been considering. Perhaps the best way of doing this is to consider not the forces between the electrified bodies, but the energy possessed by them. If the energy depends on the electrification there will be forces between two electrified bodies. Now, the potential energy depends on the electrification, and this dependence produces the

* See Clausius "On the Employment of the Electrodynamic Potential for the Determination of the Ponderomotive and Electromotive Forces," *Phil. Mag.*, 1880, V. 10, p. 255.

Digitized by Google

ordinary electrostatic forces between two electrified bodies at rest. If, however, the kinetic energy as well as the potential depends on the electrification, then the forces between two electrified bodies in motion will be different from the forces between the same bodies at rest. An easy way of seeing this is by means of Lagrange's equations.

If T be the kinetic energy, and x a co-ordinate of any kind, then we have, by Lagrange's equations,

$$\frac{d}{dt}\frac{d\mathrm{T}}{d\dot{x}} - \frac{dt}{dx} = \text{external force of type } x.$$

Hence if we have any term T′ in the expression for the kinetic energy, we may, if we like, regard it as producing a force equal to

$$-\frac{d}{dt}\frac{d\mathrm{T}'}{d\dot{x}} + \frac{d\mathrm{T}'}{dx}.$$

A simple illustration of this is afforded by the centrifugal force. In the expression for the kinetic energy of a moving particle there is the term

$$\tfrac{1}{2}mr^2\dot{\theta}^2,$$

where r is the distance of the particle from some fixed point, and θ the angle which the radius from this point to the particle makes with some fixed line; m is the mass of the particle. This term, by the above rule, will give rise to a force of type r, *i.e.*, along the radius vector equal to

$$mr\dot{\theta}^2,$$

and this is the ordinary centrifugal force.

Now let us consider a moving electrified body. If it is symmetrical, and moves in an isotropic dielectric, it is evident that the electrification, if it enters at all, can only enter as a factor of the total velocity q, and cannot affect the separate components of the velocity differently.

Let us suppose that the body is charged with a quantity of electricity denoted by e, then the kinetic energy, if it depends on the electrification, must be of the form

$$\tfrac{1}{2}mq^2 + f(e)\,q^2,$$

where $f(e)$ denotes some function of e. Now $f(e)$ must be always positive, for if it were negative we could make

$$\tfrac{1}{2}m + f(e)$$

negative, and then the electrified body would behave like one of negative mass. The simplest form satisfying this condition which we can take for $f(e)$ is αe^2, where α is some positive constant; so that the form of expression for the kinetic energy may be taken as

$$(\tfrac{1}{2}m + \alpha e^2)\,q^2.$$

Now let us go on to the case where we have two electrified bodies present, with charges e and e' of electricity; let m and m' be their masses, q, q' their velocities, of which the components parallel to the axes of x, y, z are (u, v, w), (u', v', w') respectively, the co-ordinates of the particles being (x, y, z), $(x', y' z')$.

If everything is symmetrical, the expression for the kinetic energy, if it only involves second powers of the charges of electricity, will be of the form

$$\tfrac{1}{2}mq^2 + \tfrac{1}{2}mq'^2 + \alpha e^2q^2 + \beta e'^2q'^2 + ee'\,\kappa\,.f\{u, v, w, u', v', w'\}$$

where $f(u, v, w, u', v', w')$ is a quadratic function of u, v, w, u', v', w'.

By Lagrange's equations we see that the last term will give rise to a force parallel to the axis of x on the particle whose charge is e equal to

$$\kappa ee'\left\{\frac{df}{dx} - \frac{d}{dt}\frac{df}{du}\right\},$$

with similar expressions for the forces parallel to y and z. We can see, by substituting in this expression, that we get Weber's law if we make

$$f = \frac{1}{r}\left\{\frac{x-x'}{r}(u-u') + \frac{y-y'}{r}(v-v') + \frac{z-z'}{r}(w-w')\right\}^2;$$

Riemann's law, if we make

$$f = \frac{1}{r}\{(u-u')^2 + (v-v')^2 + (w-w')^2\};$$

Clausius's law, if we make

$$f = \frac{1}{r}\{uu' + vv' + ww'\};$$

and that we cannot get Gauss's law in this way; this is in accordance with the fact that Gauss's law does not satisfy the principle of the conservation of energy. This way of considering the theories enables us to see that neither Weber's nor Riemann's formulæ can be right, for if they were, an electrified body, when in presence of another, would, under certain circumstances, behave as if its mass were negative. Thus take Weber's law as an example; let us suppose that two electrified bodies are moving along the line joining them, which we may take as the axis of x; then the expression for the kinetic energy, putting in the value of f, which corresponds to Weber's law, is

$$\tfrac{1}{2}mq^2 + \tfrac{1}{2}mq'^2 + \alpha e^2q^2 + \beta e'^2q'^2 + \frac{\kappa ee'}{r}\{q - q'\}^2,$$

so that if

$$\tfrac{1}{2}m + \alpha e^2 + \frac{\kappa ee'}{r}$$

be negative, then the coefficient of q^2 in the kinetic energy will be negative, and the body will behave as if its mass were negative; and, by sufficiently increasing e' or diminishing r, we can make this expression negative, so that Weber's law leads to results which are inconsistent with experience. This result of Weber's law was first pointed out by Helmholtz.*

Exactly the same objection applies to Riemann's theory, and indeed we see that it will apply to any theory which makes the force between two electrified bodies depend on *relative* velocities and accelerations.

(To be continued.)

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting of this Society, on Thursday, 25th ult., Prof. HUGHES in the chair, it was announced, at the request of Dr. Stone, that tickets for his forthcoming Lumleian Lectures might be had of the Secretary of this Society, Mr. F. H. Webb, and that its members were invited to attend. The subject of the lectures would be "The Electrical Condition of the Human Body: the Body considered as an Electrolyte."

The following paper, on "Electrical Lighting by Means of Low Resistance Glow Lamps," was then read by the author, Mr. ALEXANDER BERNSTEIN, foreign member:—

It is not uncommon in the history of technical science to find that constructions which have at one time been abandoned on account of apparently insurmountable difficulties have, after a certain lapse of time, been re-adopted. The high-speed engine, the high-pressure boiler, the multiple telegraph system, were known and made long before they were generally applied, because their practical application was impossible until a certain amount of experience had been obtained by means of the low-speed steam engine, the low-pressure boiler, and the single telegraph system. In a very similar manner the low-resistance glow lamp was known and made more than thirty years ago, but has hitherto been considered impracticable. In the meantime the glow lamp of high resistance has made its way, and has met with considerable success. Now to-night I desire to revive the older type of lamps in a new form produced by means of our present experience, and to show at the same time the way in which these lamps may be made to answer the purpose of electric lighting.

As we have been so often told that the lamp of low resistance is neither practical nor economical, I must suppose that most electricians are somewhat prejudiced against it. But prejudices are detrimental to the development of truth, and I must therefore request you to take as impartial a view as possible of the case which I shall lay before you to-night. High or low resistance of glow lamps is not merely a question of construction of the lamp itself; it is a question of principle which determines the whole system of lighting. The requirements of the dynamo, the sizes of the conductor, and the whole system of arranging the circuit, are entirely dependent upon the lamp which we select. It is, therefore, not sufficient to compare different types of lamps in regard to their qualities as lamps; it is quite as essential to consider how the use of these lamps answers the practical purpose of electric lighting. I shall, therefore, divide my paper

* *Ueber die Theorie der Elektrodynamik.* "Crelle," Vol. LXXV., p. 535. Collected Works, Bd. 1, S. 647.

Digitized by Google

into two parts—the first dealing with the lamp itself, the second with the manner of its application. In speaking of glow lamps, and considering their merits, I shall only take such lamps into consideration in which carbon is brought to a state of incandescence, and emits light by reason of its elevated temperature. Although other substances may be used, experience has shown so far that none of them offer the advantages which are secured by the use of carbon, viz., the possibility of applying a very high degree of temperature. This is very essential, because the highest temperature implies the greatest efficiency; and efficiency, together with durability, are the two qualities which principally determine the merit of an incandescent lamp.

Before proceeding any further, allow me briefly to enumerate the principal parts which constitute an incandescent lamp. These are only four—the glass bulb, the conducting wires (which always consist of platinum as far as they are surrounded by glass), the light-giving carbon, and the connection between the carbon and the wires (generally called the mounts). The simple construction of such a lamp does certainly not indicate that its manufacture is beset with so many difficulties. In order to settle our terminology, I shall further mention that the reciprocal of the number of watts required for every candle-power of light emitted will be called the "strain;" so that the strain is small if the number of watts per candle is comparatively large. The light which is emitted by incandescent carbon depends only upon its temperature and the amount of its radiating surface; but the energy which is required to maintain this light would be determined—irrespective of the losses which may occur in the lamp, and under the supposition that the state of vacuum and the exterior temperature remain unaltered—by those same two magnitudes alone, if the radiating power of all carbon were alike. It seems to me that this last is not the case. From certain analogies, well known in physical science, we may conclude that a black, sooty carbon will radiate more heat than a carbon of a dense greyish surface raised to the same temperature, and consequently the former will require a larger supply of electric energy to maintain it at the same temperature than the latter. This fact seems entirely borne out by observations made on glow lamps.

Let us now consider the peculiarities of a glow lamp of high resistance, say of 100 volts and 0·6 ampere. I select this lamp because it seems that this is approximately the highest resistance lamp which can be practically applied at the present time. At least, I can see no reason why the complicated expedient of a multiple-wire system should be used, if electric lamps can be made reliable when working at a much higher difference of potential and with a corresponding smaller current. As the lamp is only to take 0·6 ampere, the filament must be exceedingly fine in order to become sufficiently heated by this current, and, moreover, the filament must be of sufficient length to obtain the necessary amount of light-giving surface. As soon as the current is passed through the filament, the latter is raised to a certain state of incandescence; and we shall therefore have to deal first of all with the effect which heat alone seems to have upon the carbon. Heat has a general tendency to expand all substances; and as it was interesting to know how far carbon is subject to the same law, I have investigated this question by means of a lamp of the following construction:—Two straight filaments are connected by means of a crosspiece of platinum in the form of a T, which acts on a lever so arranged as to indicate ten times the elongation of the filaments when these are heated. The annexed sketch, in which A A are the filaments and B the indicating lever,

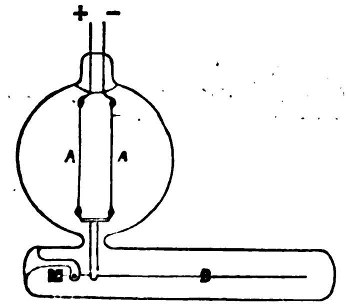

Fig. 1.

shows the arrangement which was adopted. The experiment indicated that when the carbon was exposed to a strain of 3 watts per candle, the elongation of the filaments amounted to 1-120th part of their length. It was further noticed that the rate of expansion was not constant, but increased with the temperature, although at the highest temperatures obtained the coefficient of expansion seemed to decrease again. The fact that the carbon expands and contracts with every change of temperature explains why lamps with slender filaments are destroyed more quickly when subjected to varying currents than when they are fed by a constant and uniform current, such as that supplied from batteries. When we look at a heated filament we notice sometimes that one small spot is brighter than the rest of the filament. This is an indication of a flaw which will sooner or later produce the disintegration of the carbon at this particular spot. These flaws are, for the most part, so minute that they cannot be perceived in the filament when cold, and only gradually show themselves when the lamp is being used. This is one of the causes which produce premature destruction of the lamp. The finer the filament the greater the danger of a flaw.

It has lately been supposed by some writers on the subject that the life of a glow lamp is in direct proportion to the diameter of the filament. Such suppositions, which are mostly made for the sake of obtaining mathematical formulæ, are far too sweeping; and all we are entitled to say is that, *cæteris paribus*, the lamp with a thick filament promises greater durability than the one with a thin filament. We have before observed that heat produces expansion of the carbon, and from this we may infer that if the heat is sufficiently high, evaporation or disintegration of the carbon would be the result. Such is the case if the carbon is of a soft quality, and raised to a very high degree of temperature; but we are fortunately in a position to produce a carbon of such dense and hard structure that there seems to be no perceptible disintegration at the temperature usually employed in incandescent lamps. If we, nevertheless, observe, in high-resistance lamps—even if worked at a strain of no more than 4 to 5 watts per candle, and a corresponding low temperature—that the carbon filaments are disintegrated, that the resistance of the lamps consequently increases, and that the glass bulbs begin to blacken, we are led to suppose that other forces must be at work which produce the destruction of the lamp. These forces are of an electrical nature, and their existence is easily explained if we consider that an electric glow lamp is at the same time a vacuum tube.

In the high-resistance lamp we have considered before, there is a difference of potential of 100 volts between the two terminals of this vacuum tube. The fact very soon makes itself apparent in the lamp. If the temperature is sufficiently high, the negative side of the carbon assumes a dark, sooty appearance, and a deposit of black loose carbon is formed on the positive platinum and mount. This action of throwing off particles of carbon from the negative side towards the positive has been the subject of a very interesting paper communicated to the Royal Society by Mr. Preece. The peculiar behaviour of high-resistance filaments is evidently the effect of a combined action of heat and electricity. The heat lessens the attraction of the particles for each other, and the electric forces produce motion. The result is the gradual deterioration and ultimate destruction of the carbon. It has often been noticed that a blue flame makes its appearance upon the positive platinum when the carbon is raised to a high state of incandescence. As no explanation of the production of this blue flame has as yet been given, I beg leave to insert here a few words respecting the most probable cause of it. All platinum, when cold, occludes a large quantity of oxygen, which is given off again when the platinum becomes heated. The black, sooty deposit of carbon on the positive platinum is just in a condition to combine readily with the oxygen, and both together form the blue flame. While the lamp is on the vacuum pump this flame may often be seen to travel up and down the platinum wire, always appearing where occluded oxygen is set free. If the pumping continues without the current being increased, the quantity of free oxygen is soon consumed, and the blue flame disappears, but reappears again if the temperature of the platinum is increased by increasing the current. Just in the same manner finished lamps will, under all normal conditions, show no blue flame, but will do so if an excessive current is passed through the lamp. In this case a blue flame is sometimes seen on the negative platinum as well. This occurs because particles of carbon find their way to the negative platinum and are oxidised there in the same manner. As the spectrum of the blue flame has been observed by Messrs. Liveing and Dewar to be that of carbonic oxide, it seems so much the more probable that the explanation here given is correct.

We have now to notice another effect of the vacuum tube. When lamps are made for very high difference of potential and corresponding small current, there seems to be a very strong tendency of the current to leap across from one terminal to another, thereby short-circuiting the lamp, destroying the filament, and fusing the platinum wires. This tendency is very strong when the current is turned on suddenly, as the carbon, being cold, then offers the highest resistance to the passage of the current. One of the conditions which it is desirable to observe in respect to a practicable lamp is that a certain excess of current such as is liable to occur in installations must not be able to destroy the lamp; and in this respect it is certain that the lamp with a thick filament is far superior to the lamp with a thin filament.

Turning to another point of practical importance, we notice the lamps with fine filaments are exceedingly subject to flickering as soon as the strength of the current varies but slightly. Variations of this kind may have their cause in irregular motive power, in slipping of a belt, or in a dynamo which is not perfectly balanced either mechanically or electrically. Such flickering will be noticed in a great many installations with small current lamps, and is exceedingly disagreeable to the eye. Now, with a large hollow carbon used in the lamp which I shall presently describe, the interior is always at a higher temperature than the exterior, and serves as a reservoir of heat which allows for certain variations in the current, without any effect on the eyes as regards the light. How are we, then, to obviate these difficulties appearing in the lamp? If the thin filament does not promise much durability, and is disadvantageous in other points mentioned—if the high difference of potential proves to be a factor in the destruction of the lamp—we must employ thick filaments and a small difference of potential; or, in other words, we must produce a low resistance lamp. I think I have sufficiently shown you the right of existence of a low resistance glow lamp, and I shall now proceed by describing the lamp which is before you, the form of which seems to be one of the best of all the varieties of low resistance lamps which I have made since 1882.

The lamp which is shown in Fig. 2 consists of a glass bulb of oval shape, into the opposite ends of which the platinum wires are sealed. In this manner the glass is placed symmetrically round each wire, and is therefore less liable to crack when heated. The carbon has the form of a straight tube mounted upon short pieces of stout platinum, which are joined to the platinum wires passing through the glass by means of flat thin copper strips, bent upon themselves so as to form springs at right angles to the direction of the carbon. In this way all parts of the lamp can expand and contract without subjecting the carbon to any injurious strain. A cap of insulating material at each end of the glass bulb provides for proper connection with the conducting wires, which may be made

Digitized by Google

to support the lamp; and this connection is made in such a manner as to prevent accidental contact of the manipulator with any part carrying a current. The success of these lamps depends on the satisfactory construction of every one of its details in an almost equal

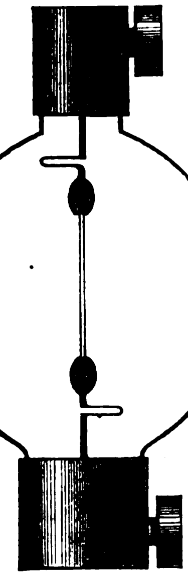

Fig. 2.

degree. The quality of the carbon, the way in which the same is mounted, the manner of surrounding the platinum wires with the proper kind of glass, the avoidance of any mechanical strain, and the proper proportion of every part of the lamp, are all the results of tedious experiments, which were necessary in order to produce a satisfactory lamp. The electrical dimensions of the lamp are as follow:—It requires a current of 9·75 amperes, thereby showing a difference of potential of 7 volts, and a hot resistance of about 0·7 ohm. When speaking of the high-resistance lamp, I have mentioned that there seems to be a limit to the difference of potential which we can apply in each bulb. As regards the low-resistance lamp, there is a limit to the strength of the current of which we can avail ourselves. The difficulty rests with the wires, which have to be sealed airtight into the glass, as it is far easier to seal in thin than thick wires carrying a large current. Before concluding this first part of my paper, I shall have to mention one of the drawbacks of the low-resistance lamps, to which Prof. Forbes has called attention in his excellent lectures on the distribution of electricity, viz., the loss of heat in the conductors inside the lamp. I quite agree with Prof. Forbes that in older types of lamps the loss was very considerable, and a serious question; but in the lamps which I made some years ago this loss amounted to only one-tenth part of the energy consumed. I am happy to inform you that in the lamp before you this loss has been reduced to one-twentieth part of the energy required in the lamp.

I shall now turn to the second part of my paper, and I consider it best to attack at once the most difficult problem which can present itself, viz., the supply of a large number of lamps from one central station, with the condition that all the lamps can be used entirely independent of each other, and with the further condition that the expenditure of mechanical energy shall always be proportioned, or, at all events, approximately proportioned, to the number of lights in use. Our imaginary plant is to be arranged for 6,000 lamps, requiring 9·75 amperes, and upon the average six volts each. Let us first look into the central station and consider its requirements. We shall settle upon the use of a dynamo which with a current of 10 amperes is capable of producing an E.M.F. of 2,000 volts—a kind of dynamo which was first applied by Mr. Brush, and which is already extensively used for arc lighting, or for a combination of arc lights with groups of glow lamps, several of the latter being always arranged in parallel. But the lamps of which I spoke at greater length in the first part of my paper are made for the passage of the whole current, and will therefore be arranged in series, one being placed in the line after the other. In this case there will be more than 300 lamps on each line; let us say 300. We shall, therefore, require 20 such dynamos, and one or two spare machines in case of repairs. These 20 dynamos may be driven from shafting, or each by a separate steam engine. There are 20 separate lines proceeding from the central station, and as the main condition of our system is that the current on every line must always be kept constant, we must provide for the regulation of each dynamo in such a manner that the E.M.F. always corresponds to the number of lamps which are in use. This regulation can be effected by automatic devices, or may be done by hand in adjusting the magnetic field or the speed of the dynamo. An ampere-meter which is placed in every circuit will indicate whether this condition is fulfilled, and a voltmeter connected with the terminals of each circuit will inform us how many lamps are used on each line at any time. A registering voltmeter placed in the same manner would be another useful addition. The central station, furthermore, contains a switch-board, which allows any one of the circuits to be connected with any one of the dynamos. If we presume that the station is to supply current day and night, it would certainly be absurd to run all the dynamos constantly at those times when only a small number of lights are required. At day time, then, I should propose to loop several circuits together, and if the total number of lamps is sufficiently low, all the 20 circuits might be looped in a single one, so that only one dynamo need be kept running. By means of an auxiliary line of lamps in the central station, dynamos and circuits may be switched in and out without any sudden change in the conditions of either. The system of working would then be that in the afternoon one dynamo after the other is switched into its respective circuit, the requirements of which can always be ascertained on the voltmeter of this circuit. If the consumption of light decreases, the dynamos are gradually switched out again. By the addition of an arrangement for observing and measuring the state of insulation of every line, the outfit of the central station might be considered complete. I have not mentioned any apparatus in connection with the central station which could not be easily constructed with the means at our disposal at the present time.

We now leave the central station, and turn our attention to the conductors. These are 20 pairs of copper wires of small size, say No. 6, well insulated. Experience has shown, so far, that there seems to be no great difficulty in insulating a wire if the tension of the current is not more than 2,000 volts. If we suppose that the central station is in Pimlico, on the banks of the Thames, a few wires may be laid in the direction of Victoria Station, a few more may reach the Houses of Parliament, some may be laid in the direction of South Kensington Museum, and some others may be used for lighting private houses—in each of which I shall suppose that, upon an average, 20 lights are used at the same time. In this case 15 houses are passed by the same conductor, which supplies current for 300 lamps. All these lights can be turned on or off at will, quite independent of each other, because we have provided in the central station that each dynamo is regulated in such a way as always to produce the same strength of current, no matter whether there are 300 lamps alight in each conductor, or only 10.

Let us now compare this system with the only other system in which glow lamps are arranged quite independent of each other, leaving out the consideration of secondary generators. In the parallel system the central station must be in the centre of the district to be lighted, which is often very objectionable, and sometimes impossible. In the series system the station may be far out of the way. In the parallel system we are restricted to the use of a 100-volt lamp, as we have seen before, and in consequence the radius of the district to be lighted must be kept very small, or the expenditure for conductors would be prohibitive. In the series system the expense for conductors is comparatively small, and we may reach any distance. The parallel system requires that a fixed difference of potential should be maintained in all the conductors under varying strength of current—a condition with which it is even theoretically impossible to comply, and which entails enormous practical difficulties. In the series system we have to maintain a constant current under varying resistances—a condition which can be easily fulfilled. When the parallel system was first developed, the prevailing idea appears to have been to make electric lighting from central stations similar to gas lighting. But the conditions under which electrical energy in its active form is best transmitted are so different from those requisite for the transmission of the potential energy of gas, that the desire to imitate the gas system has proved rather a disadvantage.

We now arrive at the last, and perhaps the most difficult, part of the whole installation, viz., the outfit of the place which is to be provided with lamps. For the sake of simplicity, I will suppose the place to consist of one single room, as shown in the sketch. In this sketch the small

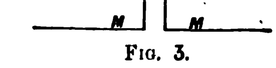

Fig. 3.

circles O, marked L, represent lamps; the squares [], marked S, represent switches (which will be presently described); and the cross +, marked V, is to indicate a registering voltmeter. The street main, M, enters the house at the main switch, drawn larger than the others; it continues from switch to switch, and returns to the main switch before leaving the house. We have supposed the street mains to be composed of No. 6 copper wire, but the house mains may be made equal in section to No. 10 wire, in order to be more flexible. The lamps are always connected to their respective switches. From what has been said before, it is quite evident that the first and essential condition of such a system must be that the circuit is never to be opened, whatever may happen. As we are always dealing with a closed circuit, it will prevent misunderstanding if we give a different designation to the two ways in which the circuit can be completed; and I shall therefore call the circuit "short-closed" if the current goes directly through the switch-lever, and "long-closed" if the current is led through the lamps or other electric devices, such as motors, which are to be acted upon. The fact that the circuit is never to be opened reduces one great difficulty in the switch required in the parallel system—viz., the liability to produce an arc. The main house switch, to which I shall now invite your

Digitized by Google

attention, serves the purpose of either short-closing the street circuit, so that no current can pass into the house, or of long-closing the same, thus including the house circuit into the main circuit. In the first case I have not considered it sufficient merely to prevent the current from entering into the house; I have thought it advisable to disconnect the house circuit entirely from the street circuit at the same operation, so that any alteration of the circuit may be made inside the house without the possibility of a branch current being established, even if the street circuit should be of defective insulation. But this switch is also made to answer another purpose. Supposing that the street circuit which has been short-closed is now to be long-closed, but that by some accident or another a break of the continuity of the line has occurred in the meantime inside the house: if now the switch-lever were to be moved with the intention of allowing the current to enter the house, the result would be the formation of a long arc, and eventually the whole current would be interrupted. The manner in which this has been rendered impossible can be best explained by reference to the annexed sketch, in

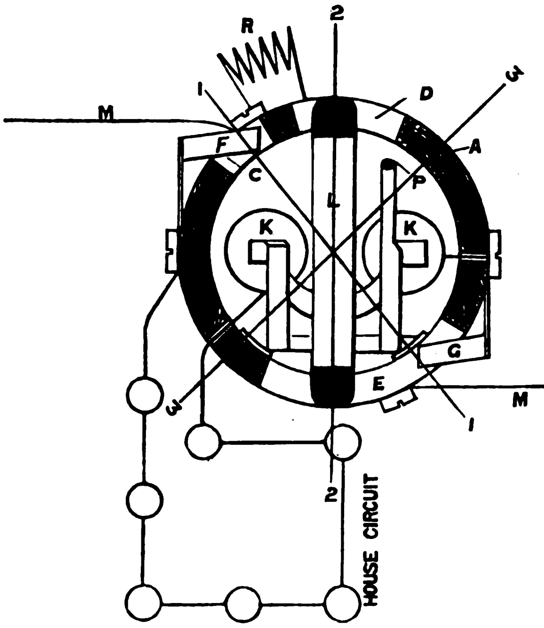

Fig. 4.

which A is the switch box, made of insulating material, and L the switch lever, made of conducting material. C, D, and E are three pieces of metal let into the upper edge of the circular box. The lever L may occupy three positions, marked 1, 2, and 3. In position 1, C is connected with E, and as C is one terminal of the main circuit and E the other, this circuit is now short closed. But if the lever L is in position 1, it lifts two flat springs of metal, F and G, which are the terminals of the house circuit, from their respective seats on the metal pieces C and E. The lever L carries on its upper side two pieces of insulating material, on which the two springs F and G now come to rest, and consequently the house circuit is out of all electrical connection with the main circuit. If it were now intended to allow the current to pass into the house circuit, the lever L would have to be turned from position 1 to position 3; but when the lever passes over the intermediate position, 2, it first connects the metal piece D with E. But the metal piece D is permanently connected with C by means of the resistance R, and the main current will therefore be divided in two parts—one, the greater portion, passing through R and L to E; the other, the smaller portion, passing through the house circuit in case the same is complete. This house circuit includes the electro-magnet K, which is situated inside the switch, and the armature of this electro-magnet carries a pin, P, which is in such a position that it is below the plane of the motion of the lever L if the armature be attracted, but hinders this motion if the armature be not attracted. In case, then, that the house circuit is complete, there will be no impediment to the further motion of the lever L from position 2. It will therefore reach position 3, where it rests upon pieces of insulating material, and the whole current now passes through the house circuit. But if the house circuit had not been completed, the motion of the lever would have been arrested by means of the pin P, and a break in the circuit is in this way made a matter of impossibility.

I shall pass at once to the lamp switch, because it is practically a mere repetition of the main switch on a smaller scale. But the lamp switch contains an additional arrangement, which would be a useful adjunct to the main switch as well, viz., the automatic cut-out. This is intended to act if the lamp should fail during the passage of the current, in which case the break of the current is prevented by short-closing it around the lamp. The arrangements which I have used to provide for this eventuality are of two kinds, and may be shortly described without reference to any drawing. Both are based on the principle that if the resistance of the lamp increases—which always occurs in lamps placed in series when the carbon gives out and an arc is formed—then a current in a shunt around the lamp will increase. In one of these arrangements this increased current is made to act upon the armature of an electro-magnet, which armature releases a spring for the purpose of making a direct secure contact between two places of the circuit in which the lamp is situated, and a short circuit is thereby formed round the lamp. In the other arrangement a fusible wire is placed in the shunt, and a lever is arranged in such a way as to be acted upon in one direction by the wire, and in the other by a strong spring. If the wire fuses, the spring presses the lever against contact pieces which serve the same purpose as specified above. In neither case can the circuit, which is now short-closed, be made to include the lamp again until the cut-out lever has been moved into its former position by hand. The combination between the switch and the cut-out lever is such that the switch-lever has to be placed into position 1 before the cut-out lever can be operated upon by hand. The reason for the adoption of this last arrangement will become evident by a consideration of the peculiarities of the switch, which I have mentioned before. I believe that in this way I have provided for the prevention of a break in the circuit which may occur from any eventuality. I need not dwell on the construction of the lampholder, the only part of the outfit which has not yet been mentioned. It may be made in different ways, but one principal idea has been adhered to in its design, as well as in that of all other details which constitute the outfit of a house; there is no part conveying a current which is not perfectly insulated, or which is in any way exposed so as to offer the possibility of any person coming into contact with it. This is hardly possible in arc light circuits, but may easily be done where only glow lamps are used.

And this brings me to the last question which I shall have to consider, namely, the question of safety. Here again I shall have to note one very great advantage of the series system over the parallel system, and this is the impossibility of a wire becoming overheated. Every experienced electrician knows a fact that short circuits in the parallel system have often led to detrimental results in spite of safety fuses; and a system in which such a danger does not exist, and which consequently does not require any provision against it, has certainly much to recommend it. Especially in such cases in which the danger of fire must be most dreaded—in ship lighting—I believe that this advantage of the series system will be very greatly appreciated.

I now come to the objection generally raised against the use of high-tension currents. If an inventor were to appear to-day saying he wanted to introduce into our houses a substance which, when properly used, was intended to give light, but which in itself was a poison, and produced poisons when used as a light, and of which it was further known that it was always ready to form an explosive agent when mixed with atmospheric air, I believe that the critical spirit of our time would raise an outcry against the introduction of such a dangerous substance, and against the use of the public streets for its conveyance. But this substance—of which we know that it is quite harmless as long as it is retained within the metal tubes—is now actually carried into all our houses, and we are so familiar with its peculiarities that no one feels any nervousness nowadays in the neighbourhood of a gas chandelier. In conveying a high-tension current into a house we are in a far more favourable position than if dealing with gas, because the probability of an accident is far more remote. Three conditions must be fulfilled before any person can be injured by an electric current. First, there must be a certain amount of leakage on the line; secondly, the person must be in contact with a bare conductor; and, thirdly, the person must at the same time be in contact with the ground. In the system of central lighting which I have laid before you it is easy enough to constantly ascertain the condition of the line, and far easier to locate a fault than in a complicated system of branch wires. It is, further, easy to construct all parts of the system inside a house in such a manner that contact with a bare conductor is impossible; and, moreover, a person standing on a carpet and a dry wooden floor is exceedingly well insulated. The tension which we can use with safety depends simply upon our means of insulation. If you will recall the precautions which have been taken in the construction of the switches by entirely disconnecting parts of the circuit from the main circuit, when lamps have to be replaced or alterations to be made in the circuit, then I think you will agree with me that the probability of an accident is exceedingly remote; and this system of lighting appears to offer more safety than any other method of artificial lighting at present in use.

And now, in conclusion, I should like to say that in a short paper like this which I have had the honour of reading to you, I found it impossible to enter more fully into details than I have done, and I have therefore restricted myself to the explanation of those details and the discussion of those questions which appear to me of prominent importance. I hope that by my humble efforts I may have accomplished the objects of my labours, namely, the further extension of the field of electric lighting.

The discussion on the above paper was opened by Mr. W. H. Preece, F.R.S., who complimented the author on having brought before the society an old subject with distinct originality. His experience of domestic electric lighting in his own house induced him to say that people who used gas in their homes had no conception of what life was like under the more wholesome conditions of electricity, and that anybody who, like Mr. Bernstein, endeavoured to bring it within the practical reach of the ordinary householder would do more good than an army of sanitary reformers. What was wanted, however, in his opinion, was cheap carbons and a cheap lamp—one that, whether it lasted only one hundred hours or as long as five hundred, could be thrown away and replaced without concern as to the cost.

Mr. Rawson pointed out some dangers which he apprehended would be incurred in changing Mr. Bernstein's pattern of lamp, and described the several risks from defects and mistakes appertaining to a system of this kind.

Digitized by Google

Mr. Crompton stated that Mr. Swan had originally designed his lamps on a system of this kind, but that mainly owing to his (Mr. Crompton's) objections the idea was abandoned. He particularly feared the danger from accidental earth when using a constant current of high tension, and pointed out that the Board of Trade had forbidden its introduction into any dwelling house. He also thought the double mount of Mr. Bernstein's lamp (which was exhibited in action) was objectionable, especially when used as a pendant.

Prof. Forbes thought the expense of the switches was a great drawback, but on the other hand a vast saving would be effected in the conductors. On the whole he thought it the safest system of any, notwithstanding what had been urged to the contrary by Messrs. Rawson and Crompton.

Sir David Salomons gave his experience of glow lamps, which, as now manufactured, were of very long duration, and he preferred them to any cheaper form which would give out sooner.

Prof. Ayrton also expressed an opinion favourable to the safety of Mr. Bernstein's system ; and was sure it might be generally used for temporary installations with secondary batteries, comparatively few of which would be required to maintain the lights.

Prof. Silvanus Thompson approved of the constant current system, and pointed out that self-induction, which was our great difficulty with the prevailing system, would be actually advantageous in the plan here suggested.

The discussion was adjourned at a late hour.

LECTURE ON ELECTRIC LIGHTING.

Last week Mr. Alexander P. Trotter, B.A., A.M.I.C.E., gave the last lecture of the season to the Halifax Literary and Philosophical Society, describing the principle and development of lighting by electricity. Dr. S. C. Smith presided. Mr. Trotter had made elaborate preparation, and, by means of power supplied at his own works a short distance away, the place was illuminated by the lamps of various makers. As he acknowledged at the conclusion of the proceedings, he was indebted to Mr. L. J. Crossley for valuable assistance. The title of the lecture, as originally announced, was "Recent Improvements in Electric Lighting." Mr. Trotter explained that he conceived it in full expectation that the winter would bring as many improvements as previous years had done, but the season had been distinctly marked by the absence of changes. The lecturer proceeded to explain the principles of the dynamo machine, but for which electric lighting would have been a plaything, and which, but for electric lighting, must have remained a mere toy. After the performance of some interesting experiments with a very powerful magnet, he observed that the use of the expression "electric current" was more convenient than accurate. In the telegraphic message the effect was probably produced without the longitudinal motion of anything in the wire. The medium employed was probably identical with that which conveys light as air does sound. Another equally incorrect phrase was "electromotive force" — it was shortened to E.M.F., and was altogether an abomination. It reminded one of the French definition of the crab, which Cuvier pointed out would have been well enough but for the fact that the crab was not red, and was not an insect, and that it did not walk backwards. Electromotive force was not electromotive, and was not force. Mr. Trotter remarked, in passing, how, by the employment of such words as amperes, volts, watts, &c., eminent electricians were immortalised. He went on to show that there is no such thing as a perfect conductor, the degree of superiority being in the following order—silver, copper, iron, German silver, platinum. The great difference between copper and iron was strikingly demonstrated by a chain composed alternately of those metals. The heat was further exhibited in a novel fashion, viz., by toasting a piece of bread, about ¾ horse-power being expended. Proceeding to the examination of the incandescent light, the lecturer spoke in detail of the results attained by Swan, Edison, and other successful inventors, whose labours caused such a panic among holders of gas shares a while ago. It was pointed out that the relative merits of these systems were pretty well determined by the question of economy, the important consideration being the relative cost of different kinds of power. There was one recently improved lamp, but it was hardly before the public. It was his (Mr. Trotter's) privilege to introduce it for the first time that night. It was a useful and an artistic lamp. It was covered at the back with opal glass, and the front was clear, and the result was a beautiful, soft light, not nearly so dazzling as the generality. It was the invention of Mr. L. J. Crossley. An apparatus for exhausting the air having been perfected, they had now the electric light in an almost perfect vacuum ; that being so, the light would not set fire to anything if the lamp were broken, and there could be no possible danger even in a cotton mill. An arc light of 30 amperes was then shown. Mr. Trotter thought such lights would only be used for special purposes. Owing to the great pressure required, he was of opinion they were not likely to meet with as general favour, by reason of the increased danger to human life, as the incandescent system. He then turned his attention to the transmission of power, which he submitted was of much more importance than the production of the electric light. Electric motors were still in their infancy, but recent tests had shown that a good dynamo was almost invariably a good motor. The comparatively small amount of power obtained from steam was a disgrace to science ; the waste was enormous. But people were always looking for cheap power ; hence the proposals respecting the employment of wind and water for electrical purposes. Mr. Trotter gave an entertaining and instructive account of the tidal machinery, but he calculated that the required outlay upon appliances and civil engineering works was almost prohibitive. It was shown that with a ten-foot tide nearly two acres would be required for every continuous horse-power, and that to light 15 lamps a tidal basin, or reservoir, would have to be reclaimed from the sea of an extent of *three acres* ; but he recommended (though against his own interest) that, when ready, it would be a better investment to burn gas and *keep a cow*. A small motor in the room was set to work for a few moments in driving a lathe, with circular saw. The lecturer concluded with an example of light measuring through the instrumentality of a very simple photometer. Several low volt lamps were overrun, amongst others were some 30 volt 20 candle-power Woodhouse and Rawson lamps. The resistance was gradually reduced till they were subjected to 70 volts, when they emitted a beautiful light of nearly 300 candles for nearly a minute. The customary vote of thanks was spoken to by the chairman, Mr. J. B. Holroyde, and Dr. Bowman.

DOMESTIC ELECTRIC LIGHTING.*

BY W. H. PREECE, F.R.S., VICE-PRESIDENT OF THE SOCIETY.

(Concluded from page 395.)

Batteries.—No isolated installation is complete without a secondary battery. It maintains regularity and uniformity of current, so as to secure absolutely steady light. It supplies a reserve of power that renders one free from accident to engine or dynamo. It supplies a store of electricity that provides the householder with a source of light at all times and seasons. If you wake in the middle of the night, there is your light ; if you have to start by an early train, and dress before daylight, by the mere pressure of a button, you have your electric lamp alight ; if you have to breakfast on a dark, foggy, murky morning, you feed in soft daylight. The secondary battery has been much before the world. Its early failures disappointed many ; it was launched before the public at too early a stage of its infancy. It has sown its wild oats, but it is now a matured, sober, practical instrument. Sir William Thomson says :—"My cells have worked to perfection. It is the greatest possible comfort to us in the house to have the light, with satisfactorily equal brilliancy, at all hours of night and day, and every day in the week. I have now cut off the gas at the meter, so that there is absolutely none used in the house. I have no oil lamps, and have not used so much as a single quarter of a candle within the last three months, and have the electric light in every part of the house where light can possibly be wanted by night or by day." I can confirm every word of this. I have now had nearly two years' experience of them, and I would just as soon dispense with them as I would with my fireplaces or bedclothes.

Originally I used them as a regulator to my gas-engine, but I speedily found that it was more convenient and economical to charge them during the day, and discharge them through the lamps at night. In the depth of winter I charge them every day ; in late autumn and early spring three times a week ; and in summer I charge only once a week. It is very easy to know when the cells are fully charged. When the charging current is put on, the E.M.F. commences at about 2 volts per cell, and gradually rises to about 2·5 per cell. It acquires its maximum only when the cells are full. The current, on the contrary, falls. The density of the liquid, which is observed by a hydrometer floating in a cell, gradually rises, and when it becomes constant, the cell is full. Several hydrometers are used. Gas is then freely given off, and the cell has a milky appearance. On the other hand, when a cell discharges the hydrometer sinks, and when it reaches a minimum point it must be charged again. The E.M.F. also commences to fall when it is too empty, but I never allow that point to be reached. Good cells give an efficiency of 70 per cent. without losing E.M.F., and with a loss of 10 per cent. they will give over 80 per cent. The useful rate of a battery is the number of ampere hours it will give before losing 10 per cent. of its E.M.F. It is quite possible to get out of a battery all, or nearly all, the energy that we put in, but we cannot do so at a useful or economical rate. I give in the appendix a record of the charge and the discharge in my house in the month of February last, and also a record of last week's work.

The durability of these cells is most satisfactory. I see no reason why they should not last ten years at least. In fact, I believe the makers will maintain them at the rate of 10 per cent. per annum. The faults that I have experienced are very few and rare. Short circuiting from peeling or buckling are things of the past. I have never seen a case of "treeing." Occasionally the connections develop resistance and get

* Paper read at the Society of Arts, March 24, 1886.

Digitized by Google

hot, but this is solely due to neglect; they require attention and cleanliness. It sometimes happens on high days or holidays that more current is wanted than can advisably be drawn from the cells; the engine is then allowed to run as well, but if the current developed by the dynamo is in excess of that used in the house, a few cells have to be taken off the battery, which is readily done by a switch, in order to maintain the E.M.F. in the house at its normal point. It is impossible, in fact, in the house to tell whether the engine is going or not. If it happens that the engine is kept continuously running, while the batteries are in action, special steps have then to be taken to prevent the cells from being irregularly charged, by changing the idle cells periodically.

A secondary battery acts perfectly as a regulator as long as its resistance is so small compared with the lamp circuit that it may be regarded as nothing, but if from any bad contact, fault, or weak cells, the resistance becomes appreciable, fluctuation in the light becomes evident, and it ceases to act efficiently. The latest form of cells are exhibited on the table, and they are now so well known that they need no description in this paper.*

Primary Batteries.—I have had no practical experience of their employment for domestic lighting, nor have I seen a house lighted up by them; but I believe there are several installations at work, and I am sure the Society will be glad to hear in the discussion some facts from those present.

Lamps.—No great progress can be chronicled in lamps like that in dynamos and secondary batteries. Their price remains very high. The ridiculous practice of giving lamps a fictitious nominal candle-power, which reached such a height of absurdity in arc lamps, and which was partially adopted with glow lamps, has nearly died out. Lamps which were called 20-candle lamps, are now sold as 16. The nomenclature of lamps is very illusory. The same lamp can be used to give 5, 10, 15 or 20 candles, according to the number of watts expended in it. A good standard glow lamp has not yet been devised. I should like to see a 10-candle lamp working under a pressure of 50 volts, and requiring half an ampere; that would mean the absorption of 25 watts, or 2½ watts per candle. Its life would not be very great at present, but if it were cheap enough, one would not mind frequent renewals. Since secondary cells are inseparable from isolated lighting, low E.M.F. means fewer cells, and therefore smaller capital expenditure, and small current means slow discharge. Ten-candle lamps are ample for domestic illumination; they lend themselves to better distribution of light. Two 10-candle lamps will give better illumination than one 20-candle lamp. My ideal lamp has not yet been placed in the market, though there are several approaches to it. There is a great variety of practice in determining the number of volts best adapted to work an installation. The conditions that regulate a central station system are quite different from those regulating domestic lighting The former requires high pressure to reduce the weight of the mains, the latter requires low pressure to reduce the number of cells. Both are governed by economical reasons. The Edison Swan Company adopt 100 volts; Sir William Thomson uses 85 volts; the Anglo-American Brush recommend 65 volts; the Electrical Power Storage Company, 60 volts; I recommend 50 volts for home lighting. I tried originally 31 volts, but I had to increase the pressure, for the low volt lamps took too much current from my cells. Makers of lamps seem to consider that there is great credit in securing long life. Unfortunately, glow lamps deteriorate sadly with age. The carbon wastes imperceptibly away, and we are scarcely conscious of the fact that, after 200 or 300 hours, the lamp gives only half the light it did at first. The fact is lamps last too long. I have been relegating my old lamps to the bed rooms, but they will not die, and I have been obliged to remove them "ere their time." The price of a lamp should be such that we can afford to give them a short and merry life. Long life is therefore an objection.

The efficiency of a lamp is generally taken to be the number of watts it consumes per candle per 1,000 hours of life; but a good measure of efficiency would be the number of hours it took to lose 10 per cent. of its normal light when absorbing 2½ watts per candle. Some interesting experiments were recently made in Berlin on this point by Mr. Wilhelm Siemens, who showed that in 800 hours an unflashed carbon, consuming 5 watts per candle, lost 37·7 per cent. of its light, falling from 19·9 candles to 11; while a flashed carbon, consuming 3·2 watts per candle, lost only 12·7 per cent., falling from 17·5 candles to 14·5. The resistance of the former increased 12·7 per cent., of the latter only 4·2 per cent. The process of flashing carbon is a process by which pure hard grey carbon is deposited upon the carbon filament by heat, decomposing some hydrocarbon gas with which the globe is filled. This deposit of carbon enables the filament to acquire a brighter surface, and attain a higher temperature before commencing to disintegrate, and therefore it gives a higher efficiency, for the amount of light given out depends simply upon the temperature.

A glow lamp, when incandesced, seems to lose its carbon mass steadily and regularly. The carbon molecules fly off, and are projected against the sides of the globe where they adhere, and cloud or discolour the glass; so that the light is diminished in two ways—first, by the wasting of the carbon, and, secondly, by its being deposited upon the glass, and preventing its radiation. The resistance increases owing to the diminution of the sectional area. This goes on until eventually, at some weak point, the mechanical strength is reduced to such a point that the filament becomes too weak to bear the slight strain upon it, and it breaks; or the density of the current becomes too high, and it dissipates away like a bright star, leaving a gap across the filament. This weak spot can often be detected by its brilliance before the lamp goes. There is a critical point in all lamps when a change of state occurs in the carbon filament. It is shown by the appearance of a beautiful blue effect pervading the whole globe. It occurs at some point between 1 and 2 watts per candle. It should be determined for each kind of lamp. I have an example of a lamp destroyed by lightning in Mr. Elwell's house, near Wolverhampton, which shows very beautifully the destructive effect on carbon of very high E.M.F. The globe is converted into a beautiful mirror. Lamps fail in giving their light occasionally from having an imperfect vacuum. This is very easily detected by feeling the globe. If the vacuum is bad it gets quite hot. Mr. J. T. Bottomley showed that a wire became red hot when the air was exhausted from the globe, though it was only 80 deg. C. when the air was in. Occasionally, but very rarely, lamps explode with a loud report when the current is first put on. This is, perhaps, due to a slight leakage of air making an explosive mixture with the residual gas. At the present moment, both the nomenclature and the efficiency of glow lamps are in a very unsatisfactory state, and we are buying pigs in a poke at a very high price. Mr. Edison adopted the very meritorious plan of determining the E.M.F. which would give his lamps a life of 1,000 hours, and the current that would give it the normal light. If this were done by every maker, it would be easy to determine the life at any other E.M.F., or the light at any other current, for the former varies with the twenty-fifth power of the E.M.F., and the latter with the sixth power of the current.

Considerable difference of opinion exists as to the character of the globe developing the carbon filament. Some like them clear, some like them ground; others envelope them in shades, generating light simply to choke it; while others, at a great loss, make the globe of a beautiful opal glass. It is very objectionable to have the optic nerve irritated by a brilliant glowing filament, but it is equally absurd to produce a good thing and then strangle it. Grounding and shading mean loss of light. Lamps can be placed so high that they need not affect the eye, and if they do the light can be so reflected as to be useful elsewhere. The art of lighting a room is to flood it with light without the delicate eye being offended with the direct rays from the source of light. An essential feature of a good lamp is a good holder, by which lamps can be readily removed and renewed. The platinum loops, which Mr. Swan originally introduced, proved very troublesome, through constant breakage. Edison's screw-holder was a much better, though more expensive thing; but Mr. Alfred Swan has recently introduced a "vitrite" holder, which embraces the merits of each, and leaves little to be desired. Switches to turn the lamps on and off are a source of great trouble in a house. As a rule they are cheap and nasty. When fixed away from the lamps they introduce into the circuit additional resistance, and therefore waste energy, but they are distinctly serviceable when they are fixed outside the door of a room, so that you can light it before you enter it. In many cases the lamp itself is its own switch, but it is objectionable to handle a lamp, and attempts have been made to utilise the weight of the lamp itself when suspended from the ceiling to maintain contact, and to break that contact when the weight is released. Cut-outs or safety-valves are essential to the security of a house. Short circuiting ought not to occur, but it does, and generally when showing off. It may occur when cleaning. The cut-out is so cheap, and so effective, that there is no excuse for its neglect. They should be fixed on every circuit.

Fittings.—The comfort and pleasure of a house depend upon its fittings. It is here that taste has its sway and art its swing, and the two are regulated only by the balance at the bank. It, however, fortunately happens that electric lighting does not lend itself to expensive fittings. The simpler they are the more effective. Sir David Salomons, who has spared no expense in obtaining energy at Broomhill, has exercised wise economy and rare taste in fixing his lamps. They are so suspended by their own conductors that in daylight you do not see them, but when darkness comes they spring into light like beautiful stars floating in the air. No one has taught us so much in this direction as Mr. Tayler-Smith, whose portable lamps and useful appliances were so much admired at the Healtheries, and at the Inventions last year. My house is full of them. I have lamps everywhere, and I can get light wherever and whenever I want it.

Wiring.—No one must imagine that electric lighting is absolutely safe from fire. It certainly possesses elements of danger, but elements that are perfectly under control. Several cases of fire have taken place, but invariably from crass ignorance. It is very simple to secure safety if the rules and regulations to avoid fire risks be carefully followed. The simplest rule is to use nothing but the best insulated wire, and to employ none but experienced men to put it up. All accidents that have occurred have arisen from careless wiring and ignorant handling. Wire has been ordered by so-called electrical engineers of such a quality that manufacturers have absolutely declined to supply it. Competition is so active, owing to the depression of business, that prices have been cut down so low that work can only be done at a profit by the use of poor stuff. In a new and growing business like electric lighting, competition should be very guardedly resorted to. There are firms of repute who are experts, and who can be trusted to carry out everything, but they are few. Protection should be procured by careful specification and constant supervision. The electrical engineer is as essential to the success of the building as the architect, and he should be engaged professionally. There is a great deal too much work done by the tradesman alone, and too little left to the expert. The design of the circuits of a house, the dimensions of conductors, the quality of materials used, the provision against fire risks, the testing of the work done, the adaptability of means to an end, should come within the province of the professional adviser, and not be left to the successful competing contractor, however eminent the firm may be.

Meters.—It is very desirable in a well-equipped house to see at a glance how many lamps are burning, how the dynamo is behaving itself, how

* Until January of this year I had been using Elwell-Parker cells at my house, but I am now trying the E.P.S. form, having removed the former to the Post Office.

Digitized by Google

much current is going per hour into the battery, how much is coming out, and how well the electric pressure of the battery is maintained. Hence it is essential to have as good a voltmeter to measure the electric pressure in our circuits as to have a barometer to measure atmospheric pressure, or a thermometer to measure temperature or heat pressure. The most efficient, reliable, and simple that I know is Cardew's. Again, we must have a good current meter, and though amperemeters are thick as autumnal leaves in Vallombrosa, they are, as a rule, uncertain and misleading, especially with fluctuating currents. Siemens's electro-dynamometer remains master of the situation. Ferranti's meter is a most admirable adjunct. In my house one measures the current going into the batteries, and another measures the current going out, so that I am able to keep an accurate debtor and creditor account against my battery. The result for February is seen in the appendix. How far these meters are accurate within a wide range has yet to be determined. They are certainly more accurate than gas meters, and they are more easily comprehended. When electricity is laid on in a house it can be used for other purposes besides illumination. Mr. Sellon uses it for heating; a current of fresh warmed air passes through a coil at a temperature of about 180 deg. Fahr. and warms water-closets and dressing rooms. He uses it even for bed warming. I have used it for cigarette lighting, and it is frequently employed for driving sewing machines. I am now trying charming little portable lamps, worked by secondary cells, made by Mr. Pitkin, which enable me to visit my cellar with comfort.

Testing.—It is most desirable that every means should be adopted in a house to test the condition of the wires and apparatus constantly. Any incipient fault in a wire would speedily develop into a serious trouble under the influence of such powerful currents as electric lighting requires. It is, therefore, essential to detect its existence at once. All the circuits in my house concentrate in one place on each floor, and they are controlled by a switch. A current indicator, or galvanometer, wound with a thick and a fine wire. The former indicates the number of lamps burning, and checks improper lighting; the latter detects any leakage on the wires when the lamps are removed from their holders. There is also a galvanometer in the engine house. Secondary batteries facilitate testing. It is quite impossible for a leak to commence without its speedy detection, and if one were to appear, the particular circuit could be isolated at once by the switch. It is often said that it is all very well for me—an expert—to rejoice over the success of electric lighting in my own house. It would be a disgrace if it were not so, but there are non-experts who have been equally successful. Mr. Walter Palmer at Reading, Sir Thomas Bazley at Fairford, Mr. Coope at Berechurch Hall, Mr. Cortauld in Essex, the Rev. Sholto Douglas in Perthshire, Mr. Tate in Streatham, and many others, have had no trouble. In fact, when the work is well done, there should be no trouble. Its working is within the reach of ordinary intelligence. As regards cost, it comes out just twice that of gas; for, though I burn no more gas than I burnt before, I have more wages to pay; there are also repairs to machinery, and the purchase of oil and waste. The lighting of my home cost me, in 1885, £60. 0s. 6d.

	£	s.	d.
Gas	£34	9	0
Oil	2	5	0
Waste	0	12	0
Brushes	0	17	0
Repairs	4	9	6
Wages	10	8	0
Lamps	7	10	0
	£60	0	6

Now, if we charge against this the value of steady light, pure air, no heat, absence of matches, candles, and oil, comfort, durability of pictures, decorations, and books, no painters, cleanliness, cheerfulness, health, gain of time, long life, there is little doubt on which side the balance will appear.

The general distribution of electricity throughout extensive areas is a much larger question than that which I have attempted to deal with in this paper. I have endeavoured to confine myself to the past, and to the teachings of experience. The future of electric lighting in England rests very much with our Legislature, which, by the Act of 1882, has materially strengthened the monopoly of gas, by preventing the growth of a young and active competitor. There never has been one word said in favour of that Act, and it is monstrous that it should be allowed to remain on the Statutes without amendment. There seems some hope of something now being done

LEGAL.

The United Telephone Company (Limited) v. Bassano and Slater.

This action was brought by the plaintiffs against the defendants, Bassano and Slater, of Traffic-street, Derby, to restrain the infringement by them of a patent now vested in the plaintiff company, and the plaintiffs sought relief by way of injunction and damages. Shortly after the argument his Lordship gave judgment for the plaintiffs, and now stated as follows the reasons on which the judgment was founded :—

Mr. Justice NORTH: The letters patent bear date the 30th of July, 1877, and were granted to Mr. Thomas Alva Edison, a gentleman whose brilliant discoveries with respect to electricity have rendered his name famous throughout the scientific world, and they relate to improvements in instruments for controlling by sound the transmission of electric currents and the reproduction of corresponding sounds at a distance, or, in other words, to telephones. The letters patent contained at first thirty different claiming clauses, but these have by disclaimers at different times been reduced to one only. The defence put in originally in the action merely denied the infringement of the patent, but after issue joined the defendants, by leave, put in a further defence by which they set up that the invention, the subject of the patent, was not novel or useful, that Edison was not the first inventor, that the specification was insufficient, and that the invention had been published in this country before the date of the letters patent in twenty-one several publications. At the trial, however, most of these points were dropped, none of the alleged cases of anticipation was relied upon or gone into, the validity of Edison's patent was not substantially challenged, and three simple issues were raised by the defendants' counsel. The final clause of the specification, as last amended, now runs as follows :—"I would observe, in conclusion, that I do not claim generally the transmission and reproduction of sound by increasing and decreasing the resistance of the circuit, nor do I claim separately any of the parts or arrangements hereinbefore described and illustrated in the accompanying drawings except as hereinafter mentioned, but I claim as my invention—first, in an instrument for transmitting electric impulses by sound, the combination with a diaphragm or tympan of electric tension regulators, substantially as hereinbefore described, for varying the resistance in a closed circuit, substantially as set forth." The claim thus being for a combination of diaphragm or tympan with electric tension regulators, as and for the purposes described, the first two points raised by the defendants are—(1) that they have not used a diaphragm or tympan which falls within the specification; (2) that they have not used a tension regulator which is within the specification; and that therefore they have not taken either of the two things the combination of which alone is claimed. If the defendants succeeded on either of these points they would be entitled to judgment, but in case of failure on both they set up a third—viz., that Edison's invention is not commercially useful, having regard especially to the tension regulator portion of it, and that there is no evidence that any such tension regulator as he describes was in actual use. I do not stop to consider in detail the various discoveries and inventions, the improvements upon which are the subject of the letters patent now before me. It is sufficient to say that before the date of that patent it was known that if two similar plates or tympans capable of vibrating were placed a short distance apart, and were mechanically connected, the vibrations caused in one of them by speaking to it would be reproduced in the other, and this would in its turn cause pulsations in the air corresponding with those which made the first vibrate, and thereby reproduce articulate speech. It was also known that by the use of the electric current certain sounds, such as musical notes, could be transmitted to considerable distances, but no mode by which articulate speech could be reproduced at long distances had yet been worked out. The question for solution was—How can the pulsations of air caused by speech be made to operate upon a continuous electric current in such a manner that the current will reproduce vibrations or pulsations of air corresponding with those which first operated upon it? The mode in which Edison solved the question was by the use of a diaphragm to receive the pulsation of sound and operate correspondingly by causing variations of resistance in the electric current, and the arrangement by which this operation was accompanied was what he calls an "electric tension regulator." It is necessary, therefore, to consider these two things separately. But before doing this I should refer to the general description of his invention given by Mr. Edison in his letters patent. He says in his specification :—"This invention relates to that class of electrical instruments in which sound becomes one of the elements in the transmission of the communication and a corresponding sound is produced at the receiving station, so that oral communication can be sent by electricity and clearly distinguished at the receiving station. Musical tones may also be sent, but my present invention is specially available in transmitting and receiving oral communications. In transmitting musical tones the respective notes each has a definite period for each vibration, hence there is a response at the receiving end from the notes that vibrate in time with the electric pulsations sent; but in speaking there is little change in the musical tone, but considerable change in the modulations and inflections of the voice. In my present invention I make use of the vibrations given to a diaphragm or tympan by speaking into a resonant case to produce a rise and fall of electrical tension upon the line with such accuracy that the electric pulsations or waves will represent the atmospheric sound waves produced by articulation, and an electro-magnet at the receiving station will respond to the electric waves in such a manner as to reproduce the articulation by acting upon a resonant plate. The transmitting instrument in a complete form is represented in sections in Figure 1, and Figure 2 represents a receiving instrument which may be employed with it. Referring to Figure 1, the resonant tube or box A is of a size and shape adapted to being spoken into, the same having an opening at one end or side and a diaphragm or diaphragms, B, against which the sound waves from the human voice act, and these and the motion that the diaphragm receives are the means of producing the rise and fall of electric tension on the line by the devices hereafter set forth, so that the battery B, connected to the line C, will transmit a greater or less current to the distant electromagnet in Figure 2, and increase or lessen the magnetism of the cores, and in so doing act upon a resonant plate c, and develop sound corresponding to the articulation at the transmitting station. The general features thus described pervade my entire invention, but, in developing the same, many useful and important modifications and variations have been made which I will proceed to set forth." After referring to some details which are not of importance for the present purpose, the inventor proceeds as follows :—"The next feature requiring consideration is the character of the diaphragm in the speaking instrument. Many materials have been used by me, such as metals, horn, vellum, celluloid, ivory, &c., but almost all of them pro-

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.
Digitized by Google

duce a prolonged or second vibration from their own resonant character, hence the articulation is defective and the sound vibrations blend." His Lordship read a further extract, in which the inventor states his preference for mica, and continued: He then gives certain details with reference to his tension regulator, which I pass by for the present with the observation that he then refers to a diaphragm "covered with plumbago," which differs somewhat from what he had previously described. He then proceeds as follows:—"I sometimes perforate the diaphragm 10, Fig. 18, and place a strip of elastic material, 40, across the said diaphragm over the hole, and upon this a piece of foil, so that the same responds to every weak vibration, and in some cases two or more diaphragms are provided at different sides of the resonant box, each with its own tension regulator, the diaphragms being either the same, or of different sizes, characters, or tensions, so as to respond to varying sounds or acoustic conditions, the various tension regulators being all in the electric circuit (line 18). This will produce greater rise and fall of tension for longer lines in consequence of the diaphragms acting simultaneously on the tension regulators." In another passage he describes a totally different arrangement for a diaphragm. "A plate supported excentrically and free at its edges when placed in the speaking tube responds advantageously to the tones of the voice; the circuit with this plate is completed through one or more tension regulators placed round its edges." In that passage the inventor does not use the phrase "diaphragm, or tympan" at all; but it is clear that he is there referring to one form of the arrangement which is elsewhere indicated by that name. From these various extracts from the specification it is obvious that Mr Edison does not confine himself to one kind of diaphragm. It is clearly pointed out that diaphragms may vary in number, and may be one, two, or more. When more than one in number they may be of the same or different sizes, characters, or tensions; they may vary in position and may be at the ends or sides or wholly or partially across the instrument, or one may be mounted upon a perforation in another. They may differ in material, though the inventor gives reasons for preferring mica, and they may be set up in different ways, for they may be strained if constructed of a membranous material like vellum, which requires straining; or if the material, like mica, does not require to be strained, the diaphragm may either be secured at its edges, or it may be supported excentrically with the edges free. The specification frequently refers to a diaphragm or tympan as though they were synonymous terms, and an argument is founded upon this that nothing could be a diaphragm within the meaning of Edison's specification unless it were more or less a tympan or drum-head also, and it was said that nothing of that character was found in the defendants' instruments. Mr. Conrad Cooke, in particular, made a strong point of this. But I agree entirely with the opinion of Lord Justice Fry that the diaphragm described is susceptible to vibration produced by the voice, and this is common to a tympan also; and I do not think that calling it a tympan means more than this. And even if it could be said that in some form Edison's diaphragm was not a tympan at all, I do not think it material that a thing is called by an inapt name when I find the thing itself described with sufficient fulness and clearness for all practical purposes—as is the case here. The next point is as to what is the diaphragm referred to in this specific case. The ordinary meaning of the word is a partition or separation; and in the present specification I think it clearly means something which is capable of vibrating, and which divides the air on one side of it so as to allow of differences of air pressure on the two sides which produce the necessary vibrations of the diaphragm. It is proved to be quite immaterial on which side of the diaphragm the tension regulator is placed, and therefore it is not in any way essential that the diaphragm should separate one portion of the instrument from another part of it. In point of fact one form of instrument shown in Edison's specification has a tension regulator on the side of the diaphragm on which the speaker is. I have read from the specification Edison's description of the object of the diaphragm; and the witnesses on both sides concur in the view that its function, as indicated throughout that specification, is to receive and take up the air-waves and pulsations of sound produced by the voice and vibrate in accordance with them, and thus produce a varying or changing pressure upon the tension regulator resulting in a varying use of all in the electrical resistance of the circuit which, the specification points out, must be closed, and further that the form or shape of the instrument which thus gathers up the air-waves is immaterial except in degree. I think the evidence of the defendants' witnesses, Prof. Forbes and Mr. Conrad Cooke, when subjected to a little pressure in cross-examination, quite as clear upon their points as that of the eminent witnesses called for the plaintiffs. It is necessary now to consider the form of the instrument the defendants have made and sold. It consists of a conical hollow mouthpiece made of thin black wood, into the open, larger end of which the voice of the speaker passes. Towards the lower end of the cone the wooden part suddenly becomes larger and forms what has been distinguished as the black base. Within this is a cylindrical chamber into which the smaller end of the cone opens, and which chamber is of considerably larger diameter than such opening. To the sides of this chamber two points or blocks of hard carbon are firmly fixed, and a pencil of similar carbon with attenuated points is supported at its ends by each pair of blocks, the points resting lightly in a larger cavity in each of the supporting blocks and being in what has been called "loose contact" with them. The other end of this cylindrical chamber in the black base is then closed by its being fastened firmly to a piece of red stained wood, which is the portion of the instrument furthest from the speaker's voice, and has been called for distinction the "red back." The carbon blocks and pencils form the defendants' tension regulator, about which I shall have to say more presently, and they are connected in the usual manner with a line wire in a closed circuit, so that the electric current passes from one block to the other through the pencil which connects them. A portion of each pencil is opposite to the opening at the thinner end of the cone, and is visible through it. When the black cone is spoken into, the tension regulator is affected in such a manner that articulate speech is reproduced at the receiving end of the closed circuit, and the question is whether the means by which such result is obtained are protected by the plaintiffs' patent. It appears quite clear to me that the use of the red back is the use of a diaphragm within the meaning of that patent. The arrangement of the black cone and base, the red back, and the tension regulator are substantially the same thing as the transmitting instrument fully described in Mr. Edison's patent, except that the tension regulator is on the nearer instead of the further side of the diaphragm, which is represented in the defendants' instrument by the red back, and this variation of its position is admitted to be of no importance. Indeed, it is proved that when the pulsations of air caused by the voice are made to strike upon the back or outside of the red back the defendants' instrument speaks quite as well as, and under some circumstances better than it does when the voice speaks into the mouthpiece in the ordinary way. It is true that in the defendants' instrument the diaphragm is made of wood, which is not mentioned by Mr. Edison as one of his materials, and the use of which substance as a diaphragm is said to have some disadvantages. But a patent cannot be infringed with impunity by the adoption of an inferior material for a given purpose in lieu of a more efficacious article indicated by the patent for the same purpose, and it is obvious from the use of other instruments, and from the defendants' own instrument, that wood will answer very well for the purpose of a diaphragm. It is not necessary for me, for the purposes of my judgment, to say more than that by the use of the instrument of which the red back forms a part the defendants have used a diaphragm within the meaning of the plaintiffs' patent. But it has been clearly proved that if the red back is taken away the rest of the defendants' instrument still operates as a good telephonic transmitter; and the question whether any combination in which the black wooden portion of the instrument, consisting of the conical mouthpiece with its back base, or either of those parts, is included is protected or not has also been fully argued, and as I have considered it carefully and have formed a clear opinion upon it, and it may be important to the parties to know what my opinion is, with a view to subsequent action, I proceed to deal with it. I entertain no doubt that the use of the black part of the defendants' instrument, as well as the red back, is the use of a diaphragm within the meaning of Edison's specification. Each of those parts separates the air on one side of it from the air on its other side, and thus allows the differences of air pressure to exist on its opposite sides which render it susceptible of vibration, when the air-waves come in contact with it, and it gathers and takes up these sounds and vibrates in accordance with them and transmits them to a tension regulator. The experiments tried by Dr. Hopkinson, the details and results of which were fully explained by him, and were not challenged by the defendants, prove this to demonstration. The trials of the several portions of the defendants' instrument as parts of a telephone which acts solely by mechanical vibration were completely successful, and the instrument spoke perfectly. The defendants' counsel attempted to make out that the operation of the defendants' instrument was produced solely by the direct impact of the sound waves upon the pencils of carbon in the defendants' tension regulator, and that the vibration of the black cone and base and the red back had nothing to do with it. But this is quite inconsistent with the result of the experiments, and also with the proved facts that the defendants' instrument speaks better when the outside of the red back is addressed than when the voice enters the mouthpiece, and that it speaks quite as well when the aperture from the narrow end of the cone into the cylindrical chamber is closed by a cork; when the cone is continued down to the red back as in J H 2; when the pencils are moved further apart in the cylindrical chamber, so as to be sheltered from the direct action of the voice, as in J H 3; and when the outside of the black cone is spoken to, as in its normal condition. In fact there is no real conflict of evidence upon the question whether these portions of the defendants' instrument performed the functions of the diaphragm as such functions are described in the plaintiffs' specification. The defendants' witnesses, when pressed in cross-examination, confirm the direct evidence of the plaintiffs' witnesses. The defendant Bassano says that these portions of his instrument are really for a totally different purpose; that the function, or main function, of the black cone is to concentrate the air-waves from the voice on the tension regulator; that the black base is to hold the carbon-blocks which support the pencils, and that the red back is merely a support for the rest of the arrangement. But even if this be so, yet if they discharge the function of the plaintiffs' diaphragm they are none the less an infringement. But the most important contention on the part of the defendants is that, even if the above-mentioned parts of their instrument so perform the functions described, still they do not come within Edison's specification. In other words, they attempt to circumscribe the area of that specification and limit it to particular kinds of diaphragms and tension regulators as much as possible. This is clearly shown in the answers of the defendant Bassano to his counsel's question whether he considered the black cone or base, or the red back, to be diaphragms, to which he replied, not by a simple negative, but by saying he did not consider them diaphragms according to the specification of Edison, and the other witnesses for the defence take the same line. So, too, the defendants' counsel press upon us that Edison's diaphragm is a distinct portion of instrument figured in his illustrations, distinguished by a letter, and shown in particular positions, and also further identified as being made of mica as the material preferred, and being in every one of these points something quite different from the parts used by the defendants which are said to be infringements. But I have already pointed out that the specification is not confined to one special form of diaphragm. On the contrary, it describes diaphragms differing in size, number, material, form, position, and otherwise, though the common function they are to perform is clearly shown. Under these circumstances it is impossible for me to hold that the patentee is limited to any special form. Indeed, his claim

Digitized by Google

is the combination of a tension regulator with a "diaphragm or tympan," not confining it to any special form, and I have heard no complaint that the claim is too large in this respect. The contention of the defendants appears to me incapable of being maintained, either upon principle or authority. As regards principle the patentee discovered a very remarkable new manufacture, and described its essential conditions, and pointed out how it was to be performed, and indicated several practical modes of carrying it into effect, and the law does not require him to describe every way of carrying it out, or limit the protection it confers to the modes particularly described. If the defendants place a diaphragm in their apparatus which performs the functions of the diaphragm in the plaintiff's apparatus, they cannot escape the charge of infringement by making a non-essential variation in the position or form of the diaphragm material. And, as regards authority, the decision of Lord Justice Fry in the case he decided seems to me to cover the present case. In the specification and drawings of the plaintiffs' patent the diaphragm is always referred to by the letter B, and this is made to operate by its vibration on an electric tension regulator in physical, but not necessarily in mechanical, connection with it. The regulator first described is of compressible bunches or tufts of elastic fibre, forming part of the circuit connected either by a diaphragm spring or secured by solder, or by a delicate cork centre-piece, or with a piece of platinum foil, *x*, in contact with the fibre; in all instances the telegraphic circuit being made by a thin strip of platinum or similar material extending to the centre from the line or battery connection. In that case it is quite clear that the piece of platinum foil is not described as part of the diaphragm nor exposed to the air-waves, though no doubt it is affected by the vibrations of the diaphragm through the cork or the spring; but is described as part of the tension regulator, and actually forms an essential part of the electric circuit. The alleged infringement before the Court on that occasion was Hunning's transmitter. His lordship discussed that case and continued: It was also said by the defendants that their instrument does not require anything in the nature of a diaphragm, that it will act perfectly without, and, therefore, that it cannot be an infringement of Edison's combination. And they appeal to the experiments made with carbon blocks and pencils. Those made by the defendants' witnesses were successful to some extent; those by Sir William Thomson did not answer so as to produce articulate speech. It is obvious that there is still room for further investigation in this direction, but the question whether the defendants could dispense with a diaphragm or not is not now before me for decision. As a matter of fact they never have done so, for they have never used thin carbon blocks and pencils in practice except in combination with the cone, the black base, and the red back, each of which, as the defendants' witnesses admit, does assist, by intercepting the sound waves vibrating synchronously with them, and so acting on the tension regulator, and they have, therefore, adopted Edison's combination unless the tension regulator they have used is outside his specification, the point I now proceed to consider. The electric tension regulator of the Edison specification is the apparatus forming a joint or link in a closed circuit, by which the vibrations of the diaphragm are made to produce a rise and fall in the electric current passing along the line wire by varying the amount of resistance, such variation being caused by increasing or diminishing, by the change of pressure, the area of surface contact within the regulator. In a passage in the specification which I have already read, Edison says that the motion of the diaphragm is the means of producing a rise and fall of electric tension on the line by the devices hereafter set forth. He also says:—"I find it is not practicable to open and close the line circuit in instruments for transmitting the human voice; the circuit to the line must be always closed, and the transmission be produced by a rise and fall of electric tension resulting from more or less resistance in the line. This resistance may be produced in several ways. I have shown several which will hereafter be named, but I find the most delicate to be small bunches and tufts or discs of semi-conducting fibre, such as particles of silk, and an intermediate conducting or semi-conducting material; this device I call an electric tension regulator; it more or less compressed according to the vibrations of the diaphragm or tympan, and the electric current rises in tension as it is compressed, or lessens as the fibre expands." He also describes an arrangement, shown in Figure 10, in which the diaphragm is placed at the end of a resonant chamber, and has at each side of it springs with points made of compressed plumbago, mixed preferably with gum or any substance not liable to rapid decomposition, or the "elastic or fibrous tension regulator aforesaid may be used." And after pointing out how this operates to vary the current by creating greater pressure upon the plumbago points on the two sides alternately, he says that, as the tension regulator of fibre or plumbago decreases and increases its resistance enormously under slight changes of pressure, it follows that the strength of the electric waves will be in proportion as the speaker's voice is strong or weak. A little further on he speaks of another arrangement by which a plumbago contact point is so arranged as to present a semi-rigid point for contact, so as to prevent a rebound and allow of a slight yield when the plumbago is pressed by the diaphragm. [His lordship further referred to the specification, and continued]: It appears clear to me, as it did to Lord Justice Fry and Lord M'Laren, that Mr. Edison did not attempt to describe every form of tension regulator to be used with instruments made under his specification; but Lord Justice Fry pointed out that the regulators he describes have three essential properties—(1) that of compressibility, in order that the area of surface contact may be capable of being increased by pressure, and the resistance to the current diminished accordingly; (2) that of resiliency, either from the natural elasticity of the substance employed or produced by artificial means, so that when the pressure is removed the material may return to its normal position, and thus check the current, which had been increased by its compression, and be in a position to repeat the operation time after time; and (3) that of semi-conductibility. In the present case the scientific witnesses on both sides agree that these three qualities must be found in Edison's tension regulator. The question then is whether the hard pencil carbon used by the defendants in their instrument, as I have explained, comes within the description of "electric tension regulators substantially as hereinbefore described," as used in Edison's specification. The plaintiffs' witnesses say that it does, for that it is semi-conductive, compressible, and resilient. The defendants' witnesses say that it does not, for it is not semi-conductive, not compressible, and therefore not resilient. And yet, when the evidence is considered attentively, there is very little, if any, difference between them after all. It is merely a question of degree. [His lordship discussed the evidence and continued]: It is also said that even if the defendants' hard carbon blocks and pencils have the attributes of Edison's tension regulators, a regulator of hard carbon is quite a different thing from any described in the specification. [His lordship stated his grounds for differing from this view, and referred to the straightforward way in which the defendant Bassano had given his evidence, and continued]: I am of opinion that the defendants' instrument is like Edison's, a combination of a diaphragm or diaphragms vibrated by the voice with an electric tension regulator consisting of a semi-conductive compressible, and resilient substance for varying the resistance of the electric current in a closed circuit, and that it is within the scope of and an infringement of Edison's specification. His lordship then shortly disposed of the point that Edison's invention was not commercially useful, and read the evidence of Sir William Thomson and Prof. Forbes to show that it was, and said that on this point also the defendants failed.

Sir R. Webster, Q.C., Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Micklem were for the plaintiffs; Mr. Bigham, Q.C., and Mr. Plumptre for the defendants.

Varley's Electric Plant Company.

In the Chancery Division of the High Court of Justice, on Thursday, before Vice-Chancellor Bacon, Mr. Ford made an *ex parte* application for the appointment of a receiver of Varley's Electric Plant Company (Limited). The application was made on behalf of Mr. Barber, a debenture holder. The interest upon the debentures became due on Wednesday, and when Mr. Barber applied for it he learned that the company was insolvent; that a resolution had been passed to wind up; that the two principal officers, the managing director and the secretary, had commenced actions to recover the amount of their salaries; and that on Wednesday, with the assent of the company, certain of their effects were seized and sold in order to pay off those claims. Under these circumstances, in order to protect the remaining assets, the debenture-holders, in the name of Mr. Barber, had commenced this action.

The Vice-Chancellor appointed a receiver, as asked.

COMPANIES' MEETINGS.

Western Counties and South Wales Telephone Company (Limited).

The first annual ordinary general meeting of the Western Counties and South Wales Telephone Company (Limited) was held on March 25th at the Grand Hotel, Broad-street, Bristol, Mr. C. Nash, Chairman of the Board of Directors, presiding. There was a very limited attendance of shareholders.

Mr. H. F. Lewis, general manager and secretary, having read the notice convening the meeting, the report, which had been printed and circulated amongst the shareholders, was taken as read.

The following are the principal features of the report:—Capital Expenditure—Reference to the capital account will show that up to the 31st December, 1885, a sum of £29,352. 16s. 1d. has been expended in the company's district; this includes the sum of £14,500 paid to the United Telephone Company. Revenue—The revenue of the Company up to the same date has been £8,729. 14s. 7d. Working Expenses—The working expenses, exclusive of royalties, for the same period have been £4,917. 5s. 2d. Preliminary Expenses—It will be observed that these have been moderate, considering the magnitude of the business dealt with, and the directors have decided to spread them over a period of five years. Maintenance—The Company's plant has been maintained and renewed out of revenue. Reserve Fund—The directors propose to place the sum of £500 to a special reserve fund, against depreciation of plant, &c. Dividend—The balance of nett revenue account is £2,327. 0s. 1d., which, after deducting the £500 proposed to be placed to the special reserve fund, and the payment of a dividend of six per cent. on the paid-up preference share capital to the 31st December, 1885, £894. 17s. 9d., leaves a balance of £932. 2s. 4d. to be carried forward to next year. Preference Capital—The directors have pleasure in saying that the first issue of 10,000 £5 preference shares has been allotted. Ordinary Capital — 25,000 ordinary shares remain in the hands of the directors to deal with in such manner as they may deem desirable for the benefit of the Company. Progress of Business—This is shown by the following figures. The number of subscribers to the various exchanges and the number of private line renters on the 31st August, 1884, and on the 31st December, 1885, were as follows:—

	Exchange Subscribers.	Private Line Renters.
December 31st, 1885	494	239
August 31st, 1884	308	171
Increase	186	68

Digitized by Google

Exchange Business—Exchanges have been opened at Bristol, Clifton, Cardiff, Newport, Plymouth, Devonport, Mutley, Torquay, and Portsmouth. Since the 31st December the Company have opened their exchange system in Bournemouth, and it is their intention to open exchanges at Aberdare, Bath, Gloucester, Great Malvern, Hereford, Llanelly, Merthyr, Neath, Pontypool, Pontypridd, Southampton, Swansea, Sharpness Docks, Weymouth, Worcester, Weston-super-Mare, and at all other places in their district where they find sufficient support. United Telephone Company—The Directors have pleasure in stating that the Company are working in perfect accord with the United Telephone Company. The accounts between the companies in connection with the transfer of the business have been satisfactorily settled. The United Telephone Company have successfully defended their master patent rights against various infringers in the Company's district.

The CHAIRMAN, in moving that the report and audited accounts be adopted, observed that though that was the first annual meeting of their local telephone company, the accounts comprised 16 months' work—that was to say, from the 1st of September, 1884, to the 31st of December, 1885. The date of holding the meeting was somewhat later than intended, some delay having arisen in consequence of the accounts being a little complicated at first. He hoped that on the whole the shareholders would consider that the result of the working had been satisfactory. He was not going to dwell on the figures, for he thought that the accounts put them very clearly, and scarcely required any explanation. Great care had been taken to charge the revenue with everything applicable to revenue, and that point was particularly noticed by the auditors, who spoke favourably on it, and in the way the stock account was kept. Mr. Lewis was, in fact, complimented on the stock account being kept in a more complete way than almost any others which the auditors had met with in their experience. One-fifth of the preliminary expenses, and one-tenth of the cost of the furniture had been written off, and they proposed to begin a reserve fund against depreciation of plant by setting aside £500. So much for the accounts, and turning to the future he thought they might all of them be reminded that the telephone in this country was quite in its infancy. In England they had about 32,000 telephones, whereas in America there were 325,000. Some people imagined that the great spread in America was because the rates were lower, but in New York the rate appeared to be £30 and upwards, whilst in Bristol it was £15, and the highest rate in Great Britain was £20 a year. In most of the large towns in America the charge was £25, but in New York alone there were more telephones than in the whole of the United Kingdom. He thought they might fairly assume that gradually, and perhaps rapidly, the telephone would increase in use in their own country. In Bristol there had been a steady progress, and if they looked at other places in their district they found that Plymouth and Torquay were likely to afford a considerable increase in their business. They had opened an exchange at Bournemouth, which had commenced in a most satisfactory manner. At once there were about fifty subscribers, and they looked forward confidently to having at least 100. Mr. Lewis, the secretary, was present, and looking over the report of the proceedings he (the Chairman) observed that they looked upon him there almost as a public benefactor. They were preparing to open exchanges at Bath, Gloucester, Sharpness, Weston-super-Mare, Worcester, Malvern, and many other places, but perhaps the most important part of their district was South Wales. Trunk lines were to be established—were, in fact, in progress between Bristol, Cardiff, Newport, Swansea, and Llanelly, and the Chairman pointed out that by an extension from Cardiff to Pontypool, and to the Rhondda Valley, Aberdare, and Merthyr, they hoped to have a network of wires to the various works and collieries in the neighbourhood. The Chairman said he would like to remind their friends of the great extent of district that the Western Counties and South Wales Telephone Company possessed. Looking at the extent of surface it was more than one-fourth of the whole of England and Wales. It was true there were not many large and populous towns, but there were a great many towns where they might look forward to a considerable telephone business. In Cornwall, he believed that the mining centre about Camborne was likely before very long to be an important telephone district for them. He observed that free communication had been given to their charitable institutions, and a few days ago Mr. Cave, the president of the Infirmary, mentioned how thankful the staff felt that telephonic communication with the Infirmary had been given. The advantage of the telephone system in case of fire had been proved over and over again, and only on Saturday last its usefulness to the police was shown in the case of a demonstration of the unemployed. Finding out what the route of the procession was likely to be the police were enabled to telephone to the various stations, so that a body of police could be placed on the line of route, and that could not have been done without the telephone. The Chairman then formally moved the adoption of the report and accounts, and the declaration of a dividend of 6 per cent. on the paid-up preference shares.

Mr. MARK WHITWILL seconded the motion, and said, like Mr. Nash, he believed that the use of the telephone was yet in its infancy. It was coming, however, to be regarded as one of the necessities of life, and nothing was likely to check its growth unless it was the obstruction of local authorities.

Mr. J. B. MORGAN (London) said that as one of the largest preference shareholders it was pleasing to him to observe that that was the first of the companies that had placed a sum to reserve account in the first year of its existence. That was highly gratifying, and though a director by nomination of the United Telephone Company (Limited), yet he was speaking from personal knowledge of telephone business all over the kingdom. After remarking that the amount of profit which that Company had made for year was very substantial, he said the United Telephone Company had made arrangements with three of the great railway companies to turn all their railway stations into telephone exchanges, and there was no reason why, by-and-bye, Bristol might not talk to London and every other station on the line of the Great Western.

Mr. BATTEN (also a director of the United Telephone Company) said he had taken a deep interest in the telephone enterprise, and was not a little disappointed that it had not progressed in England with the rapidity it had on the other side of the water. The speaker referred to his experience of the advantages of the telephone service in South America, and mentioned instances in which tradesmen found that to be upon the telephone exchange was of great service to them. During the recent riots in London the Telephone Company could have furnished the police authorities with 4,000 points of attack, and Mr. Morgan and himself being in the board room on the day in question were enabled to warn some of the banks.

The resolution was unanimously adopted.

On the motion of the CHAIRMAN, seconded by Mr. H. FEDDEN, it was resolved that a sum of £500 be placed to a special reserve fund for depreciation of plant.

Mr. Chas. Nash, Mr. Mark Whitwill, Commander Forsyth, R.N.; Mr. Henry Fedden, Mr. Thomas Pole, and Mr. Richard Cory were re-elected directors, and Messrs. Tribe, Clarke, and Co. were re-appointed auditors.

The CHAIRMAN said they had in Mr. Lewis, the secretary and manager, a most valuable officer, and he thought they should not leave without expressing the opinion they entertained of Mr. Lewis's services. He did not think they could possibly have a more efficient officer, and he moved that the best thanks of the shareholders be given him.

Mr. MORGAN, in seconding the resolution, said Mr. Lewis had worked under him before coming to Bristol, and he had pleasure in bearing testimony to his business capacity, and his manliness of character.

Mr. WHITWILL, in supporting the resolution, said he had never met with a man with quite so much zeal and energy as Mr. Lewis, and remarked that the Chairman and himself were accustomed to speak of him as the indefatigable.

Commander FORSYTH having also borne testimony to the value of Mr. Lewis's services,

The resolution was carried by acclamation.

Mr. LEWIS briefly acknowledged the resolution.

An extraordinary general meeting was then held for the purpose of making certain alterations in the Articles of Association, and resolutions approving the same were unanimously adopted.

A vote of thanks was passed to the Chairman, and the meeting terminated

NOTES.

West Indies.—The cables between St. Lucia and St. Vincent, and between Dominica and Guadeloupe are interrupted.

The West Coast of America Telegraph Company.—The gross earnings of this company for the month ending March 31st amounted to £3,525.

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 2nd April amounted to £3,076.

Uruguay.—The telegraph lines in Uruguay are many of them interrupted in consequence of the revolution, and telegrams for that country are accepted now at the sender's risk only.

Electricity for Tramcars.—The North Metropolitan Tramways Company are seeking parliamentary powers for applying electricity as a motive power on their system of tramways.

Direct Spanish Telegraph Company.—The estimated traffic receipts of this company for the month of March, amounted to £1,751, against £1,467 in the corresponding period of last year.

The Eastern Extension, Australasia, and China Telegraph Company.—The traffic receipts of this company for the month of March amounted to £37,804, and to £46,193 in the corresponding period of 1885.

Government Telephony.—From the "Statesman's Year Book" we find that in March, 1885, the Telegraph Department had 27 telephone exchanges open in various country towns, with 1,141 subscribers, paying £22,600 yearly.

The Lighting of Rouen.—A small company has been formed in Rouen for the purpose of establishing a central electric light station. The cables are to be carried overhead, and the Gerard incandescent lamp will be employed throughout the town.

Elementary Lectures.—Prof. Gray, of the University College of North Wales, intends giving a series of lectures on electricity. The lectures are specially intended for the working classes, who will only be called upon to pay a nominal fee for the course.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended 2nd April were £2,482, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Direct United States Cable Company.—The Board on April 2nd resolved upon the payment of an interim dividend of 3s. per share, being at the rate of 3 per cent. per annum, for the quarter ending March 31st, such dividend to be payable on and after the 24th inst.

Great Northern Telegraph Company. — The traffic receipts of this company amounted in March, to £20,000; from 1st January to 31st March, to £58,680; while in the corresponding months of 1885 and 1884 they amounted to £64,400 and £60,600 respectively.

The West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ended 31st March are £3,067, as compared with £4,010 in the corresponding period of 1885. The December receipts, estimated at £4,455, realised £4,557.

Fire at Liverpool.—Early on Wednesday morning a fire broke out in the chief telephone office at Liverpool Exchange-buildings, and all the instruments were more or less damaged. A delay of a few days will occur before telephonic communication can be completely restored in the town.

Electric Lighting Bills.—The Select Committee on these Bills is composed of the following members:—Earl Cowper, the Earl of Camperdown, Viscount Bury, Lord Balfour of Burley, Lord Rayleigh, the Earl of Crawford and Balcarres, Lord Methuen, Lord Houghton, and Lord Lingen.

Instructing the Multitude.—A lecture on the electric light was given in St. Mary's school room, Isleworth, on Monday evening last by Mr. P. J. Kelly, A.S.T.E. The experiments were numerous and successful, and the lecture was highly appreciated by the audience, especially the demonstration of the Eric Bruce system of balloon signalling.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this company during the month of March was 3,940, estimated to produce £3,300, against 4,121 messages, producing £3,510, in the corresponding month of last year. The traffic receipts for the month of December, estimated at £2,450, realised £2,448.

Abandonment of a Central Station Scheme.—Our contemporary, the *Bulletin International De l'Electricité* remarks that the electric lighting of the Magasins du Palais Royal has been discontinued. The scheme of establishing a central electric light station in that quarter of Paris has been abandoned, as it was found impossible to obtain the necessary capital.

Killed by an Electric Gun.—Mr. C. C. Seyton, of Walton-on-Thames, was accidently killed recently while examining an electric gun at his office in George-yard, Lombard-street, City. Death was instantaneous, the charge having entered the heart. Mr. Seyton was introducing the gun, which is an American invention, into this country, and read a paper on the subject at the United Service Institution on Friday last.

Lighting Contracts.—Tenders are required for lighting by electricity the Albert Palace, Battersea. Contractors are to supply 30 arc lamps and about 3,000 incandescent lamps, five candle-power each, with all necessary steam power, dynamos, &c., for the season of about four months, commencing at the end of May next. Tenders are to be sent in by the 17th inst. to Mr. William Holland, Albert Palace, Battersea Park, S.W.

How to Catch a Thief.—Frederick Johnson, 24, was charged with stealing a pair of boots, value 4s. 11d., from the shop of Mr. S. P. Weston, of Kensington-gardens. Prosecutor displays boots outside his shop, connected by wires with an electric bell in the shop. On Tuesday afternoon the bell rang, and an assistant went to the door, and he saw the prisoner and another man making off. He pursued prisoner, and caught him in Kensington-street.

Sale of Electrical Plant. — We have received from Messrs. Wheatley Kirk, Price and Goulty, the auctioneers, a catalogue of the plant in and upon the works of the British Electric Light Company (in liquidation), which is to be sold on Tuesday next. There are nearly four hundred lots—many of which represent good and useful material — including carbons, switches, lathes, drilling and milling machines, arc lamps, dynamos, and a Marshall and Sons 14 horse-power engine.

Anglo-American Telegraph Company.—At a meeting of the Board of Directors of the Anglo-American Telegraph Company, held 2nd April, it was resolved, after placing the

Digitized by Google

sum of £25,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending 31st March of 5s. per cent. on the ordinary stock, and 10s. per cent. on the preferred stock, less income-tax, payable on the 1st May, to the stockholders registered on the books of the company on 31st March.

PHOSPHOR BRONZE WIRE.—We understand that Mr. F. Geere Howard, of the Cleveland Works, Fitzroy-square, has been appointed sole agent for Great Britain for the phosphor bronze wire and castings manufactured by the Phosphor Bronze Company, of Brussels. It is well known that there has been considerable competition on the Continent between the makers of phosphor bronze wire, and we believe this company claims to produce a wire equal in all respects to that of any competitor.

COMPETITION FOR A PRIZE.—The King of the Belgians, Leopold II., offers annually a prize of £1,000 for the best essay on a given subject. The competition is open every alternate year to the whole world. The subject for the essay at the next international competition is "The Progress of Electricity Applied to Motive Power and Illumination: its Applications and Economical Advantages." The essays for competition, which must be written in French or translated into that language, are to be sent before January 1st, 1889, to the Minister of Agriculture, Industry and Public Works, from whom the conditions of the competition may be obtained.

THE "BUCCANEER."—The good folks at Brighton had their attention the other day attracted by the firing of fourteen rounds from a steamship which was anchored some distance off the town. Many assertions were made as to the cause of this, but on inquiry at the Coastguard Station it was ascertained that it had no special import. The vessel was the screw steamship "Buccaneer," with a crew of sixty, belonging to the Silvertown Telegraph Company, London, and had previously been signalling to the Coastguard. She was bound for London, having come from Teneriffe, where the crew have been laying telegraph wires between Spain and Teneriffe.

EXPERIMENTS IN LIGHTHOUSE ILLUMINANTS.—In the House of Commons on Tuesday Sir J. Corry asked whether the President of the Board of Trade would lay upon the table of the House an account of the expenditure incurred by the Trinity House in carrying out the experiments in lighthouse illuminants at the South Foreland, and Mr. C. Acland replied that the expenditure incurred in and about the experiments in question will amount to about £9,000. It is defrayed out of the Mercantile Marine Fund, which is a fund arising from charges on shipping. The grounds for this expense are that it will, we hope, lead, not only to increased efficiency, but to economy in the management of the lights.

HOW MUCH IS AN AMPERE?—Everybody can form some sort of mental picture as regards the flow of liquids. Thus, if we are told that a pipe discharges water at the rate of a gallon a second, we know what that means. But if we are told that the discharge taking place between two conductors across an intervening air space is so many coulombs or a certain fraction of a coulomb, we are at a loss to imagine what this really means. Most of those who last Saturday, at the Society of Arts, saw the thick bundle of sparks passing between the conductors of the Wimshurst machine would probably have been greatly astounded if told how much electricity was passing. It seemed a perfect torrent, and yet it was only the two-thousandth part of an ampere. At that rate it would take over half an hour to pass a coulomb from one electrode to the other.

THE PERFORMANCE OF SMALL ELECTRO-MOTORS.—The results of experiments by Prof. Anthony, recently published in the *Journal* of the Franklin Institute, show that there is room for improvement in small motors. We give here a few of the figures:—

Type of Motor.	Speed.	Horse-power obtained.	Commercial Efficiency.
De Meritens	3,240	0·455	49·5 per cent.
Gerard..............	3,330	0·225	39·5 „
Gerard..............	1,390	0·990	30·3 „

When comparing the energy obtainable with the weight of the motor we find that in the De Meritens motor 1 horse-power is obtained with 150lb. dead weight, whilst in the two Gerard motors it was obtained with 200lb. and 300lb. respectively. These figures compare very unfavourably with the usual English practice. Most motors, even small ones, made in this country develop 1 horse-power for about 100lb. dead weight, and there are some which weigh only about ½ cwt. per horse-power.

GORDON'S COLLEGE, ABERDEEN.—The arrangements for lighting several of the class rooms in Gordon's College with the electric light have been completed. At the preliminary trial of the dynamo and lamps, which took place last week, Dr. Beveridge, Mr. A. O. Gill, and ex-Baillie Paterson were present to see the results obtained. The dynamo has been manufactured by Messrs. D. Prentice, Menzies, and Co., Glasgow. It is driven by the college gas engine, and with 3½ horse-power showed itself at the first trial capable of giving a steady light with from 20 to 25 lamps. Five rooms have been fitted up with incandescent lamps, in all 51 lamps; but as never more than two of these rooms are required to be lighted at the same time, the current given by the machine is quite sufficient for the purpose. A great advantage in this system of lighting is that, as the lamps may be distributed throughout the whole room, the illumination is very equal, and thus extremely suitable for drawing class rooms, as was amply demonstrated at the trial. With the addition of a set of accumulators the plant now at the college is sufficient to work simultaneously from 40 to 60 lamps with a steady light.

CITY AND GUILDS OF LONDON INSTITUTE.—The sixth annual report of this Institute, dated March 31st, has just been issued, and shows satisfactory progress in its work during the past twelve months. An additional donation of £1,000 has been made by the Drapers' Company for the purchase of apparatus at the Finsbury Technical College, and the subscription from the same company has been raised from £4,500 to £6,000 for additional accommodation at the College for the Art School and for the increasing number of students in the other departments. The Mercers' Company also have increased their subscription from £2,000 a year to £3,000; the Salters' Company, from £525 to £1,000; the Ironmongers' Company, from £350 to £500; the Skinners' Company, from £500 to £1,500; the Clothworkers' Company, from £3,000 to £4,000; the Leathersellers' Company, from £500 to £750; the Carpenters' Company, from £250 to £500; and the Coopers' Company, from £105 to £157. 10s. The Cutlers' Company have promised to contribute £105 per annum; as also have several other companies who now for the first time give their adhesion and support to the objects of the Institute.

AUDENSHAW.—Mr. Abel Buckley, M.P. for Prestwich (Lancs.), has lately introduced the electric light into his new residence at Audenshaw, near Manchester. The installation consists 89 18 candle-power 65 volt lamps, supplied from 35 accumulators having a capacity of 300 ampere hours, which

Digitized by Google

are charged during the daytime by a B_2 Victoria dynamo machine. Mr. Buckley was so convinced of the reliability of the electric light under ordinary care that he decided from the commencement not to lay on the gas to those rooms which were to be furnished with incandescent lamps. As a consequence of this step the more or less clumsy appearance of fittings doing duty for both gas and electricity has been entirely avoided, and has enabled a great deal of attention to be paid to this important matter. The fittings, supplied by Messrs. B. Verity and Sons, have been well matched with the decorations of the various rooms, and a specially designed electrolier of beaten bronze for the dining room is the work of Messrs. Ellwood and Co., of Leicester. The motive power consists of a 4 horse-power Otto gas engine, and the whole installation is under the care of Mr. Buckley's gardener. The work was carried out by the Anglo-American Brush Electric Light Corporation.

Couples in Saline Solutions.—Mr. B. C. Damien, in a paper on the E.M.F. of current yielded by metallic couples in simple saline solutions, according to an abstract in the Chemical Society's *Journal*, finds, from a large number of determinations, that the E.M.F., as a rule, decreases with the time the couple is immersed. In the case, however, of the zinc copper couple in solutions of the chlorides, the E.M.F. at first slowly increases. The E.M.F. of the current yielded by a zinc copper couple in a solution of magnesium sulphate is very constant, scarcely varying 0·017 volt during 12 months, and is not appreciably affected by changes either of the strength of the solution or of temperature. By introducing an exterior resistance of 20,000 ohms, the current becomes practically invariable, even when the couple is kept in circuit. The author proposes to employ this couple for the generation of currents of standard strength. The zinc-copper couple yields currents whose E.M.F. is almost identical for members of any class of salts containing a given acid, but varies greatly with a change of acids; amalgamation of the zinc slightly increases the E.M.F. at first, but it decreases more rapidly than is the case when unamalgamated zinc is employed. The current obtained from a platinum and amalgamated zinc couple in dilute sulphuric acid has its maximum E.M.F. when its solution contains 30 per cent. of acid.

M. Marcel Deprez's New Coulomb Meter.—In a note presented to the French Academy of Science, M. Deprez described his new coulomb meter, consisting of a U shaped glass tube, the ends of which are formed into one closed by large glass bulbs. Into one of the branches are soldered platinum wires forming electrodes, and a second pair of platinum wires are soldered into the corresponding bulb. This bulb, the whole of the branch, and a small portion of the other branch are filled with acidulated water, whilst the other bulb and the remaining portion of the branch contain air. If a current be sent through the electrodes, gas is evolved which accumulates in the bulb, depressing the level of the liquid there and raising it in the other branch. A suitable scale attached to this branch serves to indicate the total quantity of electricity which has passed in a given time. It is worthy of notice that neither the barometric condition of the atmosphere nor its hygrometric condition have any influence on the accuracy of the reading, the apparatus being hermetically sealed. The only precaution necessary to be observed is to keep the two branches of the U tube at the same temperature. The second pair of wires in the glass bulb serves to explode the mixture of hydrogen and oxygen by an electric spark, when it is desired to refill the bulb with liquid, and prepare the instrument for another reading.

An Electric Travelling Crane.—The Compagnie des Entrepots et Magasins Généraux in Paris have large warehouses in Roubaix, where the cotton bales arriving mostly from Australia and La Plata are stored before being forwarded to the different cotton mills. On account of the great fire risk no steam crane is permitted in the establishment, and the bales, which measure about 1½ cube yard, and weigh half a ton each, had, until recently, to be hoisted and generally handled by manual labour. Now the work is done by an electric travelling crane. The crane post is placed on a trolly, which runs on rails, and a rail fixed to the ceiling of the warehouse guides the upper end of the post. The jib of the crane can be raised or lowered, somewhat after the fashion of the cranes employed by builders, and thus the distance of the load from the post can be varied. The jib can also swing all round, and the bale can be deposited in any position covered by the sweep of the jib. On the trolly is fixed a small Gramme 4 horse-power dynamo, running at 900 revolutions a minute when fed with 15 amperes at 250 volts pressure. By suitable gear the dynamo, which is always kept running, can be made to hoist the load, advance the crane on the rails, swing the jib round, or raise or lower it. The current is conveyed to the crane by overhead sliding contacts. The generator is a 6 horse-power Gramme dynamo, running at 1,200 revolutions a minute, and the commercial efficiency of the whole system is said to be 60 per cent. Formerly ten men could handle 150 bales in 18 to 20 hours. The electric crane, attended by four men, does the same work in three hours.—*Revue Industrielle.*

Electro-Magnetic Action on Polarised and Natural Light.—*Wiedemann's Annalen*, No. 2, contains some interesting communications on this subject, which are commented on by our contemporary *Nature*, as follows:—"In regard to the electro magnetic rotation of light, Herr Kundt notes the fact that all simple substances hitherto examined, be they strongly magnetic or strongly diamagnetic, show positive electromagnetic rotation. Negative rotation is shown only by chemical compounds, and such as contain atoms of strongly magnetic elements (as iron salts). Positive rotation has been proved in the case of eleven elements, viz., Fe, Co, Ni, Br, Se, S, P, C (diamond), O, N, H. The question whether electromagnetic forces may not have demonstrable action on natural as well as polarised light has been lately taken up by Herr Sohncke. His guiding idea was this:—It is known that two polarised light rays from the same source, meeting at a sufficiently acute angle, interfere most if they are polarised parallel, and not at all if polarised at right angles, to each other. Now, natural rays of light from the same source behave, in regard to interference, quite like parallel polarised rays; and it seemed likely that two such rays would lose their power of interference if the direction of vibration (or greater ellipse-axis) of one of them were turned round by electro-magnetic forces 90 deg. relatively to the other, for in this case the two rays would behave like two polarised at right angles to each other. This was effected (in a way he describes). It appears that the same thing was done some years ago by Prof. Abbe, using with natural light the natural rotation of a right and left quartz instead of electro-magnetic; and this before-unpublished method is also developed by Herr Sohncke, who describes a new interference experiment with natural light.

Addresses on Telegrams.—Mr. Joseph D. Weston, M.P., having waited upon Lord Wolverton, the Postmaster-General, and presented to him a memorial from Bristol in reference to the requirement recently made for the registration of addresses,

Digitized by Google

has just received a reply from the Postmaster-General's secretary, in which he says that, in consequence of the enormous increase which has taken place since the new rate for telegrams was introduced in the number of telegrams which have been insufficiently addressed, it has been found necessary to discontinue the practice formerly adopted of referring to directories in order to supplement these insufficient addresses. Not only was much labour involved by the references, but the telegrams of other persons which were fully addressed were thereby delayed. In the case, therefore, of vaguely-addressed telegrams their delivery is now, as a rule, effected only in the event of their falling into the hands of telegraphists or messengers who know the precise address of the persons for whom they are intended. At the same time, the Postmaster-General feels that some distinction ought to be made between cases in which the addresses of telegrams have been intentionally curtailed so as to save expense and cases in which any vagueness of the address has not been intentional, and he has accordingly given directions that when the sender has evidently done his best to give a full address a relaxation of the rule is, as far as possible, to be permitted. It is obvious, however, that differences of opinion may arise as to the latitude to be allowed, and his lordship cannot, therefore, too strongly urge that the addresses of telegrams should be made sufficiently complete to enable delivery to be effected without dispute or delay. With regard to the concluding statement in the memorial, to the effect that the action of the Department would seem to indicate a desire to compel the public to pay fees for the registration of abbreviated addresses, it is far from Lord Wolverton's wish that the registered abbreviated address system should be extended, and he would much prefer that full addresses should be given.

Electric Lighting at Greenlands, Henley-on-Thames. The final contract for lighting by electricity the above well-known residence of the Right Hon. W. H. Smith has now been definitely signed and settled, and the order placed in the hands of Messrs. R. E. Crompton and Co., thus adding another instance of the steady progress of electric lighting in private mansions, and making an addition to the large number of such contracts which Messrs. Crompton have successfully undertaken. The specification of the above work, which is of an exceptionally binding nature, has been drawn up by Mr. Musgrave Heaphy, and this gentleman, together with Mr. Massey, will act on behalf of Mr. Smith. The details of the contract may be generally stated as follows :—The plant will consist of one 12 horse-power nominal compound engine, fitted with automatic gear, fly-wheels being used, each driving by belting one shunt-wound Crompton machine of the size known as pattern No. VIII. The boiler, which, together with the engine, is being supplied by Messrs. Davey, Paxman, is also 12 horse-power nominal, the locomotive type, with special copper fire-box. The engine and boiler will be fixed on independent foundations. The rest of the plant consists of a feed water heater, an inspirator, and an electric governor, together with 60 secondary batteries, guaranteed to maintain 60 lamps at their nominal brightness for 10 hours, this point being specially insisted upon in Mr. Smith's behalf in order to avoid Sunday working. The mains, which are heavy enough to carry current for 300 lamps (110 volts), are laid underground from the engine room to the house, and are of extra heavy insulation. The total number of lamps at present required is 200, but everything is arranged so that, if desired, an addition can be made to the lamps hereafter. The fittings are generally speaking of a simple character, where-ever suitable flexible pendants being used, in other cases brackets or table standards are employed ; all switches and cut-outs have to be mounted on non-combustible bases, and, we need hardly add, all wires have to be run in strict accordance with the rules of the Phœnix Fire Office. The contractors have to guarantee the efficient working of the installation in every respect for a period of twelve months, including the secondary batteries. The contract is to be completed by July 1st, after which date we shall hope to be able to supply some further details as to the actual working and the actual arrangement of the plant.

The U.S. Government and the Bell Telephone.—On the 23rd ult. a bill of complaint was brought by the United States Government, in the States Circuit Court at Columbus, to annul and vacate the Bell telephone patents, on the ground of fraud, alleged to have been practised by Alexander Graham Bell in obtaining his patents by the connivance of persons holding official positions in the U.S. Patent Office, and by misrepresentations made in his behalf. With Mr. Bell's name are coupled as respondents several large telephone companies in the States, who are summoned to appear by May 1 and to file answers to the charge by June 1. It is complained that Bell's patent of February 14, 1876, was so ambiguously worded as to cover antecedent and future inventions and to deceive the examiners ; that it was designed as an improvement in telegraphy and not as a means of transmitting speech, which Bell knew to have been already invented by the German, Philip Reis. It is also alleged that Elisha Gray, of Chicago, filed a similar application on the same day, but before Bell filed his ; and that the particulars of Gray's caveat, which really described a speaking telephone, was wrongfully divulged to Bell by the examining officer of the Patent Office. Bell, it is stated, followed up this knowledge, and induced some of the patent officers to further violate the statutory requirements of secrecy by setting on foot an inquiry for Bell's benefit as to the precise time of day when Gray's caveat was filed, "and thereupon, without any certain proof, and contrary to law and the custom of the office, it was determined, contrary to the fact that said caveat (Gray's) was filed after said application (Bell's), although on the same day." The complaint then sets forth that Bell now having access to Gray's invention, recast his own specification and claims, so as to exclude those of Gray, especially by the substitution of the terms "undulatory" currents for "pulsatory," and "gradually" for "alternately." Further, that by false representation of Gray's attorney, Bell induced him to persuade Gray that it was no use proceeding with his patent, and that Gray in consequence did not proceed with it as he might legally and rightfully have done. Bell it is asserted did not obtain articulate speech on his telephone till March 10th, 1876, three days after the patent was issued to him, and this not with any device described in his specification, but by the method described in Gray's caveat, to which he, Bell, had had access. Even, however, if Gray's caveat had not been filed, Bell's patent, it is contended by the State prosecution, would still be void, because "all his claims are bad in form and substance." They are also invalidated by the prior inventions of Reis, Varley, Meucci, Gray, Edison, Eaton, and others. Lastly, it is charged in respect of the magneto telephone patent of January, 1877, that the invention was Dolbear's, but was appropriated by Bell, who, by misrepresentation, deterred the inventor from taking steps to protect it by a patent. This extraordinary case is exciting much attention in the States, where enormous interests are involved in the issues to be tried.

The Resistance in the Voltaic Arc.—According to Edlund, the apparent resistance of the voltaic arc consists, as

Digitized by Google

it were, of two parts, one independent of the length of the arc, and the other proportional to it. Call the resistance w, the length of arc l, while a and b are two constants, then $w = a + b\,l$. This holds if current is constant while length of arc is changed. Of the constants b is less when the current increases, while a is almost independent of the strength of the current, and of the electromotive force of the source of electricity; it is only when this is so much diminished that an arc light is scarcely formed that the value of a becomes less. The question may be put whether this constant a represents a resistance of transition, which takes place at the surface of contact of the electrodes and the air, or whether it has its origin in an electromotive force, for the diminution in the strength of the current expressed by a might be explained by either of these assumptions. From previous researches he finds a represents an electromotive force in opposition to the principal current. Frölich came to the conclusion that either of the assumptions are reconcilable with these observations, though he seems inclined to think that the constant a represents an electromotive force, as well as a resistance of transition. Frölich probably considers that a cannot be exclusively an electromotive force, for in this case it would have what, in his opinion, is the absurdly high value of 39 volts. Peukert has made a series of observations on this subject, in which the strength of the current varied from 10 to 30 amperes. He found that the apparent resistance of the luminous arc may be represented by the formula $w = a + b\,l$. If it be assumed that the constant a is an electromotive force, its value according to Peukert must amount to 35 volts; a value which appeared to him so high that he did not venture to assume it could have its origin in an electromotive force, but that, partly at least, it represents a resistance of transition. From Edlund's previous investigations it follows that a is independent both of the magnitude of the source of the current and of its strength, provided this does not sink to the lowest limit in which a voltaic arc may be formed. In his first experiments on this subject he calculated a as an electromotive force, expressed in Bunsen elements. Seven successive experiments made with a current of 53 to 79 Bunsen elements gave the following results :—$a = 24{,}416$; 25,962; 25,354; 20,951; 21,637; 21,483; 23,119; the mean of which is $= 23{\cdot}315$. This holds when the light is produced between carbon points of the ordinary kind. If it be assumed that 1 Bunsen element is equal to 1·7 Daniell's, and that this is 1·08 volt, 1 Bunsen = 1·8 volt. If this number be multiplied by the mean in question, we obtain 41·97 volts. The mean of this number and of that found by Frölich and Peukert (39 and 35) gives 38·66 volts. The view that the constant a partly represents a resistance of transition is disproved by the investigations of Victor von Lang, who succeeded in proving that the voltaic arc does contain a counter electromotive force which is equal to 39 volts. As this value of the counter force in the arc is almost equal to the value of the constant a above given, it follows that there is no resistance of transition in the voltaic arc, and that therefore the entire diminution of the strength of the current which results from the production of the arc light is caused by the resistance of the arc $b\,l$, and by the electromotive force contained in it.

Central Electrical Laboratory in Paris.—The International Society of Electricians in Paris have recently presented to the French Minister of Posts and Telegraphs a report on the proposed central electrical laboratory. At the Electrical Exhibition in Paris in 1881 it had been decided to devote any surplus which might be made to the erection of a laboratory or some such institution. We learn from the *Revue Internationale de l'Electricité*, the paper of the society, that the sum actually at their disposal was at the close of the Exhibition about £13,000. M. George Berger, the president of the society, has since contributed £240, making a total of £13,240. The committee appointed by the society to elaborate a scheme direct attention to the fact that at the present moment there does not exist in Europe any large and independent electrical laboratory. Institutions of that nature, but on a very limited scale, are generally found annexed to some university or polytechnic school, and the only attempt to establish a laboratory on a wider basis was in connection with the exhibition in 1882 in Munich. Even this is annexed to the polytechnic school in Munich, and has, for want of funds, never developed in the manner anticipated by its founders. A central laboratory, to be of real use to the progress of electrical industries, must be accessible, without distinction of nationality, to all scientists, inventors, and manufacturers, and it must, moreover, be free from any supervision or restriction imposed by the State or any of the national scientific societies in France. The primary object is to give the public an unbiassed opinion on any invention, French or foreign, which is submitted for test. It is also intended to be a central office for electrical standards and exact measurements. A free library and reading room are to be attached, and lectures on electrical subjects are to be given. The administration is to be in the hands of a committee composed of the different electrical societies in Europe, and the management is to be entrusted to a scientific electrician of high standing, assisted by a staff of engineers. It is suggested that the municipality of Paris make a present of the site for the laboratory, which will be a building covering about 1,100 square yards, having two stories and a basement. The cost of this building is estimated at £14,000, to which must be added the cost of machinery, apparatus, and internal fittings, valued at £5,000—total, £19,000. This exceeds the funds in hand by about £6,000, which will have to be asked from Parliament. An annual subvention of £1,200 will also have to be asked from Government. The annual working expenses are estimated as follows :—

Salaries	£1,000
Purchase and maintenance of apparatus	1,000
Maintenance of building and furniture	200
Experiments	600
Contingencies	400
	£3,200

We cannot help thinking that the committee of the International Society of Electricians have greatly underestimated the annual working expenses. It is difficult to see, for example, how the services of a scientific electrician of high standing, assisted by a staff of experienced engineers, can be secured at a total salary of £1,000. The appointment of a scientific manager is of so much importance that the salary of £1,000 would hardly be sufficient to cover this alone, to say nothing of the salaries of the engineers and the wages of the attendants. It must not be forgotten that a favourable verdict obtained for any new invention from the central laboratory will be of immense commercial value, and that therefore the men whose duty it will be to pronounce a verdict must be paid on a sufficiently liberal scale to put them beyond the reach of a bribe. The sum of £600 set down to defray the cost of experiments is also ridiculously small. To make careful experiments the apparatus must in each case be more or less altered and adapted, and when the experiments are to embrace all the applications of electricity, from a surgical incandescent lamp and primary cell to a thousand-light dynamo, the amount of appliances required will represent a considerable annual outlay.

Digitized by Google

REPORT ON ECONOMY TEST OF A CROMPTON DYNAMO, DRIVEN DIRECT BY A WILLANS HIGH-SPEED ENGINE.

The object of the trial was :—

1st. To ascertain correctly the cousumption of water per indicated horse-power per hour, of the new type of tandem compound high-speed engines recently introduced by Willans and Robinson, of Thames Ditton.

2nd. To ascertain what percentage of the indicated horse-power in the engine cylinders can be obtained as useful electrical horse-power at the terminals of the Crompton dynamo, driven direct by one of these engines.

3rd. The above data being correctly ascertained, to show the consumption in pounds of water, hence pounds of coal per useful electrical horse-power per hour.

Mr. J. Macfarlane Gray, Chief Examiner of Engineers to the Board of Trade, Mr. W. H. Massey, C.E., of Twyford, Berks, Dr. Fleming, of University College, London, were invited to conduct the trials. On the date on which they were to take place, Mr. Massey, being unavoidably absent owing to illness, requested Mr. E. H. Liveing to take his place. Mr. Macfarlane Gray and Mr. Liveing took charge of the indicating apparatus, measurements of water used, and all measurements relating to the engine. Dr. Fleming took all the electrical measurements, and afterwards verified the instruments used.

wrought iron magnets 24in. by 7in. thick, the armature being 36in. long and 16½in, in diameter. One end of the armature spindle is bolted to the crank-shaft of the engine by a solid steel coupling ; the other or commutator end of the spindle is carried in a spherical bearing, so formed as to be easily adjusted and kept in line with the three main bearings of the engine crank shaft. This dynamo was designed to give an electrical output of 600 volts and 120 amperes at a speed of 400 revolutions. This is equal to 72,000 watts or about 97 electrical horse-power.

Means Adopted to Ascertain the Quantity of Water used by the Engine.—The engine was supplied by a pair of nominal 20 horse-power locomotive boilers made by Messrs. Marshall, Sons, and Co., of Gainsborough, being two of the boilers usually employed for driving Messrs. Crompton's works. The ordinary feed arrangement was disconnected, and the boilers were supplied by a pair of Hancock's inspirators drawing from an iron tank, which at the commencement of the trial was filled up to a gauge mark, and at the end of the trial was again filled up to the same mark. The whole of the water passed into this tank through a barrel mounted on an accurately adjusted scale beam, so that its actual weight was taken and no calculations were necessary. The coal used during the trial was weighed, but as the boilers were not specially cleaned for the occasion the evaporative efficiency was not high. However, the actual results obtained are noted in the tables.

CURVES OF ELECTRICAL OUTPUT AND MECHANICAL INDICATED HORSE-POWER OF VIENNA DYNAMO No. 1,123 AND EXCITER.

No. 1 = Electrical H.-P. of $\frac{72}{600}$. No. 2 = Indicated H.-P. of Large Willans Engine.

No. 3 = Electrical H.-P. of $\frac{72}{600}$ – Exciter Electrical H.-P.

Description of the Engine.—The engine tested is one of Messrs. Willans and Robinson's latest design and make. It is non-condensing and single acting, having two high-pressure and two low-pressure cylinders, the high-pressure cylinders being 11in. diameter, placed on the top of the low-pressure cylinders, which are 18in. in diameter, both having 9in. stroke. The arrangement of this engine was fully described and shown with diagrams during the discussion on Mr. Imray's paper on high-speed engines recently read before the Institution of Civil Engineers. The engine was designed to run at a speed varying from 200 to 400 revolutions, and to develop at the higher speed 140 indicated horse-power, with boiler pressure of 140lb. per square inch. As a matter of fact it will be seen from the indicator diagrams that the engine is rather too large for this work.

The Indicating gear consisted of four Crosby indicators; the high pressure indicators had 120lb. springs, the low-pressure ones 50lb. springs. The two low-pressure indicators were also arranged to indicate the variations of the receiver pressure, for, as the under side of the high-pressure cylinder is open to the receiver, the variations of pressure in the latter affect the power of the engine.

The number of revolutions was taken from a Youngs speed indicator, driven directly off the engine, checked in addition by counting the revolutions with an ordin ary geared speed counter (at the end of the spindle) at the time that each set of indicator diagrams was taken.

The Crompton dynamo is of the vertical type, having

Method Adopted to Ascertain the Electrical Output.—A large rheostat or resistance coil was prepared, consisting of a continuous band of wire gauze stretched tightly over a large frame, and so arranged with switches that any desired portion could be short-circuited and the resistance thus varied. The conductors from the terminals were led to this rheostat, and from thence to the measuring instruments, which were placed in Messrs. Crompton's test room. These instruments consisted of two of Messrs. Crompton's current indicators, specially constructed for the occasion, and carefully calibrated by Dr. Fleming by means of a Clark standard cell, verified against those used by Lord Rayleigh, in conjunction with a low resistance, also carefully determined. The current indicators were calibrated by passing the same current through them and the low resistance coil, and measuring the difference of potential at the ends of the latter by means of the said cell.

Separate Exciting.—The dynamo had its field magnets excited by a separate machine. During the trials this separate machine was driven by its own Willans engine, the steam for which was supplied from a separate boiler. The electrical horse-power used in exciting was subtracted from the electrical output, as will be hereafter shown.

Electrical Measurements of Dynamo:—

Resistance armature, hot = 0·255 ohms.
Resistance magnet coils, hot = 0·33 ohm.
Loss in armature at 120 amperes = 30·6 volts.
Loss in magnet coils at 64 amperes exciting current = 21·1 volts.

Watts expended in armature	=30·6 × 120=	3,670
Watts expended in exciting	=21·1 × 64=	1,350
Watts in external circuits, *i.e.*, useful output	= 600 × 120=	72,000
Total watts ...		=77,020

Percentage of total electrical power in external circuit =93·5 per cent.

It was arranged that the indicated horse-power should be worked out from the indicator diagrams by Mr. Macfarlane Gray and Mr. Liveing independently.

Tables I. to III. give the results worked out from 48 diagrams by the former, who employed a planimeter.

Table IV. gives the results worked out from 24 diagrams only, by the latter, who used scales. The slight difference in the measurement produces a divergence in the final result as follows:—Mr. Macfarlane Gray shows the mean indicated horse-power during the experiment to be 113·98, and the water evaporated per indicated horse-power per hour 22·95lbs. Mr. Liveing shows a mean indicated horse-power during the experiment of 110·76, and the water evaporated per indicated horse-power per hour 23·66lbs. This difference is not due to the selection by Mr. Liveing of 24 in place of the whole 48 diagrams, for the same 24 diagrams taken at Mr. Gray's measurement give a mean of 113·26 horse-power, against 113·9 horse-power for the whole 48.

Table V. gives Dr. Fleming's measurements of electrical horse-power, each of these measurements being taken simultaneously by signal with the corresponding set of indicator diagrams.

Table VI. is compiled from the former tables for the purpose of showing what percentage of the indicated horse-power in the engine cylinders is obtained as useful electrical

Digitized by Google

indicated horse-power at the terminals of the dynamo, and diagram No. VII. shows the same graphically. For the purpose of compiling Table VI. and diagram VII. the mean of Mr. Macfarlane Gray's and Mr. Liveing's figures has been taken.

The electrical horse-power absorbed in exciting is deducted from the electrical horse-power shown on Table V., as would have been the case if the dynamo had been self-exciting, and the nett electrical horse-power is shown in column 5 of Table VI. The efficiency in this table varies from 79 to 66 per cent., the mean throughout the trial showing 74·05 per cent. of the indicated horse-power given off as nett useful electrical horse-power at the terminals of the dynamo.

It was originally intended to make the trial of four hours' duration, but it was found difficult at first to make the times of the indicator diagrams coincide exactly with those of the electrical readings. The early ones were therefore rejected, and those of the last two hours only taken. It will be seen from the diagram, Table VII., that there was a considerable variation in the horse-power, the cause being that both the large engine and the exciting engine were incomplete, being intended for use with electric governors, which were not ready in time for the trials; moreover, the load being a heavy one for the boilers, the steam pressure at first was not kept very regularly.

Owing to the system adopted of weighing the water, it was possible to obtain with the utmost exactness the quantity used during the two hours of the trial; but this could not be the case with the coal, as the quantity was weighed out for the whole run. However, dividing the total weight of water evaporated during the four hours by the coal consumed during the same period we find that 7·42lb. of water only were evaporated per lb. of coal. The total weight of water evaporated during the actual trial, lasting two hours two minutes, was 5,320lbs.; therefore, the results in lbs. of water per horse-power and per electrical horse-power per hour, viz., 23·2lb. and 31·31lb. respectively, are exceedingly good—in fact, there are no published results which show even an approximate approach to this measure of steam consumption per electrical horse-power.

Good though these results are, it would hardly be fair either to the engine or dynamo to take them as representing their maximum efficiency, for the boilers were not sufficiently powerful for the work and could not be cleaned for the trials. It is therefore more correct to eliminate the boilers from the calculation by taking the steam used instead of the coal, though even then an error creeps in, as the steam was probably rather wet from insensible priming due to the forcing of the boilers. Moreover, the condensation in the steam pipes was considerable, owing to the temporary nature of the connections. When these drawbacks are taken into account, and it is further considered that it was apparent from the indicator diagrams taken during the trial that far greater economical results would have been obtained at a higher horse-power had the boilers permitted it, there seem fair grounds for expecting a consumption little exceeding 20lb. of steam per indicated horse-power per hour, or 27lb. per electrical horse-power per hour, and this, with a good boiler, is equal to 2lb. and 2·7lb. coal respectively. Boiler pressure 130lb. to 140lb.

In cases where a condenser can be used there would be a further increase in the ecomony.

These trials show that the view held for so many years that a high-speed engine must necessarily be wasteful must be definitely given up, for in this case we have a high-speed engine showing under not the most favourable circumstances an economical use of steam which need not fear comparison with that of any other slow-speed steam engine; but it is capable, as has been shown, of still further improvements.

The bearing of this fact upon the future of electric lighting is most important. A great step has been made in the direction of economical production of electrical energy from the fuel, and it seems probable that the typical dynamo of the future for large installations must be one driven direct by a high-speed steam engine of from 150 to 200 horse-power.

J. A. FLEMING.
E. H. LIVEING.

MINIMUM WASTE AND MAXIMUM ECONOMY.

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

We are all of us much indebted to Sir William Thomson for his remarkable paper given at the meeting of the British Association in 1881, since it possessed a double value. First, it directed the attention of electrical engineers to the importance of determining the conditions of maximum economy, when we had a choice of expenditure in two directions of such a nature that increasing the one expenditure diminished the other; for example, it was this paper of Sir William Thomson's that suggested to us the method that we published

Digitized by Google

about a year ago for determining what was the most economical potential difference to use with a particular type of incandescent lamps.* Secondly, this paper of Sir W. Thomson's showed people how to determine the most economical gauge to give to a wire when we knew the current, the yearly value of a horse-power, the value of copper, and the rate of interest on money. But what we have desired to point out in our paper "On Economy in Electrical Conductors," recently published in *The Electrician*, is that, although his rule is perfectly correct mathematically, it cannot generally be used to determine the conditions of maximum economy, because some electrical condition, either in addition to the strength of the current, or in place of the strength of the current, is given us. Indeed, in the application made by Sir William Thomson of his own rule in his inaugural address he *starts* by assuming that we know the potential difference at the dynamo end of the line, which he takes as 80,000 volts. He next says let us employ a solid copper wire half an inch in diameter, &c.

To obtain the most economical current he uses his rule

$$C = \frac{t}{r},$$

and as 48·85 is the value he takes for t, and 0·2035 ohm the value he takes for r, the resistance per mile of his conductor half an inch in diameter, he concludes that the proper value to give to C is 240 amperes.

But we deferentially suggest that this is incorrect, because, as we pointed out, his rule has been obtained by finding the value of r that makes the total waste per mile

$$C^2 r + \frac{t^2}{r}$$

a minimum when C is constant and r a variable, and it cannot, therefore, be used to find the value of C when r is fixed and C is the variaable, which are the conditions of Sir William's Niagara problem, as he has stated it. In fact, if we regard r as constant, and C as the variable, the value of C that makes the expression for the total waste per mile a minimum is C equal to nought, and it is perfectly true that C equal to nought leads in this case *to minimum waste, but not, of course, to maximum economy*. In fact, when C alone is the variable a consideration of the waste does not lead to a practicable answer; and consequently with the conditions that Sir William Thomson has taken with the Niagara problem a method of procedure different from the one that he has adopted must be followed in order to determine the value of C that should be used to obtain maximum economy.

In the problem solved in our paper we have considered that the power given out at the other end of the line was fixed, but as this is not one of the conditions of the Niagara problem the method followed in that paper cannot be employed either.

Probably the simplest way of attacking the Niagara problem is to determine the value of C that makes the *efficiency a maximum*. This may be done as follows :—

If V is the potential difference at the dynamo, n the length of the line in miles, then the power in watts received at the far end is

$$C\,(V - C\,n\,r),$$

and the power put into the line in watts equals

$$C\,V + n\frac{t^2}{r},$$

the second term in the latter expression representing the power put in in the form of interest on the capital that has been expended on the conductor. Hence the efficiency equals

$$\frac{C\,(V - C\,n\,r)}{C\,V + n\frac{t^2}{r}}.$$

Differentiating with respect to C, and equating to nought, we find that

$$C = \frac{t}{r} \times \frac{\sqrt{n^2 t^2 + V^2} - n\,t}{V}$$

makes the efficiency a maximum.

* *Electrician*, page 309, February 21st, 1885.

Hence we see that $\frac{t}{r}$, as given by Sir William Thomson, must be multiplied by the factor

$$\frac{\sqrt{n^2 t^2 + V^2} - n\,t}{V},$$

a factor depending on the length of the line, and on the potential difference at the dynamo, in order to obtain the proper value of C.

For V equal to 80,000 volts and n equal to 300 miles this factor becomes 0·8333,

so that with the 300 miles of copper conductor half an inch in diameter the proper current to employ with the particular number of hours of working, the cost of copper, the rate of interest on money, and the yearly value of a horse-power at Niagara taken by Sir W. Thomson is, we submit, not 240 amperes, as given in his inaugural address, but

$$240 \times 0{\cdot}8333,$$

or 200 amperes,

in order to obtain maximum efficiency.

LITERATURE.

International Telegraph Convention; with Berlin Revision of Service Regulations and Tariffs. Translated by ALFRED BRASHER, Director of Traffic, Indo-European Government Telegraph Department.

Mr. Brasher has again translated the "International Telegraph Convention," which becomes more voluminous after each succeeding Convention, and now contains 111 pages. The following article (No. LXII.) relating to semaphoric telegraphs should be made known to captains of ships :—

1. Semaphoric telegrams are telegrams exchanged with ships at sea by the medium of semaphores established, or to be established, on the coasts of any of the contracting States.

2. They should be written either in the language of the country in which is situated the semaphore station which has to signal them, or in signals of the universal commercial code. In the latter case they are considered as cipher telegrams.

3. When they are for ships at sea the address should contain, in addition to the ordinary direction, the name or official number of the vessel and its nationality.

4. In the case of Government semaphoric telegrams signalled from a ship at sea, the seal is replaced by the distinctive sign of command. The name of the vessel should be given.

5. Every semaphoric telegram must contain the official instruction semaphoric in the preamble.

6. The charge for telegrams exchanged with ships at sea, by the medium of semaphores, is fixed at one shilling and eightpence per telegram. This charge is added to the cost of its transmission by the electric telegraph, calculated according to the ordinary rules. The total is collected from the sender for telegrams addressed to ships at sea, and from the receiver for telegrams signalled from ships at sea. In the latter case the instruction, — s. — d. *to be collected*, should be inserted in the preamble. If it cannot be collected, the terminal administration is paid the amount of charges due, by means of a reimbursement draft. Article LXIII. says :—

(1.) Telegrams from a ship at sea are transmitted to their destination in signals of the commercial code when the ship requests it.

(2.) When the ship does not request it, they are translated into ordinary language by the chief of the semaphore station, and transmitted to destination.

(3.) Telegrams which it has been impossible to signal from semaphore stations to the ships to which they are addressed within thirty days of the date of their original deposit (date of deposit included) are considered as dead letters.

(4.) In case the ship to which a semaphoric telegram is addressed does not arrive within the term of twenty-eight days, the semaphore station forwards a service notice to the sender on the morning of the twenty-ninth day. The sender has the power, on paying for an ordinary aërial telegram of ten words, to request the retention of his telegram for another thirty days, and so on. If this request is not made, the telegram is treated as a dead letter on the thirtieth day.

THREE ELECTRIC LIGHTING ACT AMENDMENT BILLS.

There is at length some prospect of the Electric Light being emancipated from the shackles put upon it four years ago. The Act of 1882 was a failure from the very first, unless we are to suppose that its framers intended it as a bar to the progress of the new illuminant, in which case they have achieved only a short-lived success. In other directions than those embraced by the Act the Electric Light has grown, both in efficiency and popularity, to such an extent that its title to be ranked as a legitimate claimant for the lighting of towns and private houses can no longer be denied. The authors of that singular piece of socialistic legislation which proposed to extinguish every solvent Electric Lighting industry "for the price of old iron" now confess that prospective confiscation is not a very promising subject to legislate upon, however alluring may be the field of immediate confiscation where nobody's leave has been asked beforehand. The present Government, which was also the Government of 1882, have been brought to their knees by the reception given to Lord RAYLEIGH'S and Viscount BURY'S Amendment Bills in the House of Lords, both of which virtually repeal the existing prohibitory Act, and one of which is pretty sure to become law. In these circumstances a rival Amendment Bill is now proffered by Ministers, embodying the concessions they are prepared to make in the direction of Free Trade for Electric Lighting industry

In discussing the character of this peace-offering, we cannot lose sight of the early history of Mr. CHAMBERLAIN'S Act. The then President of the Board of Trade originally proposed that the period during which electric lighting undertakers should be free to carry on their business without liability to being summarily bought up by a local authority for a nominal sum was seven years. This term, it is true, was extended under pressure in the House of Commons to fourteen years; and afterwards, thanks to the House of Lords, a further grace of seven years was grudgingly assented to. But it was confessedly a mere try-on; and, as nobody responded to this spider-like invitation, although it has been open for nearly four years, the present Board of Trade have consented to further enlarge the term by ten years, or by ten years more if the Board of Trade and Parliament see fit, or by twelve years if the local authorities do not care to buy at the expiration of the first thirty. The conditions of purchase, however, remain as before; the spider is the same, though the net is bigger. All the difference we can see between the first overture and the last is that the agony phase is postponed. By the time the final decade has been reached all the strong and wideawake flies will have made off with the spoils, leaving the weakly ones to die of fright, or be devoured in the parish parlour. If honest people will not invest capital in a concern that is doomed to extinction at the end of seven or fourteen years, the only effect of extending the period will be to induce those who accept it to make a rush for all the profit they can squeeze out of the earlier years, so that they may bequeath extremely little for compulsory sale at the finish.

It is impossible to regard this seven years limit for a natural industrial operation except in one of two lights. Either it was thought that the Electric Light was sure of such a splendid, instant, and universal success that investors would recoup themselves for their outlay, and retire smiling in the short space of seven years; or else that the condition was so outrageously discouraging that the Electric Light would be snuffed out once and for all. Whichever of these hypotheses we choose to adopt, the Board of Trade is seen in a very discreditable attitude; and what we are anxious to point out now is that the attitude has in no way changed. Nearly or remotely, the property of this new industry is to be handed over to local bodies whether the owners like it or not, and at a figure which must in any case tell most injuriously both on their interests and on those of the public, who are sure to be badly served in the closing years of an expiring business. The bogey which has lately haunted the Board of Trade is the "creation of fresh vested interests;" and its aspect is so appalling that rather than create any more interests that are "vested" every interest whatsoever may in future be stripped naked. Some people are talking of land just now as if when it belongs to a landlord it is "national property," but when it belongs to a peasant it is the peasant's own; and, similarly, the Board of Trade seems to argue that when an industrial undertaking remains in the hands of private individuals it is criminal; but transferred to the members of a parish vestry it becomes respectable. We have had plenty of experience of vested monopolies, and by this time we ought to be able to legislate so as to safeguard ourselves against abuses in any new enterprise proposed to be started. But to attempt this by prospective confiscation will result not only in getting rid of the shadow, but in destroying the substance as well.

In respect to the length of life of the provisional order there is not much difference between the Government Bill and the Bill introduced by Viscount BURY; but the terms of purchase make all the difference. As to this the Board of Trade is still

Digitized by Google

impenitent. Lord GRIMTHORPE'S description of that part of the 27th Clause which the Government would still leave operative is by no means a caricature. A corporation of any town is to be allowed to buy a going concern for something less than it was worth from those who had had the risk of starting it and keeping it going. In support of that proposition Lord GRIMTHORPE remarked that he had heard nothing "except that the corporations would like it." "It was uncertain whether electric lighting companies would be successful or not; nevertheless the House was asked to give corporations the opportunity of playing the game of 'Heads I win, tails you lose' with those companies. If the companies paid and became prosperous, the corporations would buy them; if not, they would leave them alone." His lordship expressed an opinion that to give municipal bodies a right which not even the State had ever before enjoyed would, instead of encouraging the development of the Electric Light, only bring into existence financially weak and incompetent companies. We entirely agree with Lord GRIMTHORPE, and we feel confident that the House of Lords, if it consents to a limitation of the term of years, will insist that the condition of transfer shall be, as set forth in Lord BURY'S Bill, a fair price for the business as "a going concern," and not at an auctioneer's valuation of old stores.

CORRESPONDENCE.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Thompson does his best to prevent this discussion from becoming useful from a scientific or practical point of view. His last letter contains nothing of scientific interest, and might, therefore, have been left without an answer were it not for the fact that it contains a misrepresentation of the remarks I made in my last letter to you. Prof. Thompson seems extremely anxious to prove to you that I have "relaxed," as he calls it, on the question of critical speed, and in the endeavour to prove this he goes so far as to distort my remark ("that I prefer to call the proper working speed that speed at which the magneto series machine becomes self-regulating") into an admission that a dynamo which is partially self-excited can have a critical speed! I said nothing of the kind, and to prevent any possibility of misunderstanding I again repeat that no motor and no dynamo which is not wholly self exciting can have a critical speed. It is equally incorrect of Prof. Thompson to say that my attack on the theory of the self-regulating motor is outside the points of correction about which he wrote. On the contrary, in the review of his book I called attention to the unsatisfactory way in which the problem of self-regulating motors had been treated. The introduction of the term critical speed was a by issue, and, moreover, any electrician could understand from the general sense of my remarks what I meant by this term. It is strange that Prof. Thompson should have failed to grasp my meaning; at any rate he dropped the main question concerning the value of his theory of self-regulating motors, and began the squabble whether one thing or another should be called critical speed. As I am desirous that this discussion should be of practical value (and should not be merely a dispute) I brought it back in my last letter to the real point at issue, Can a constant current motor, constructed on the basis of the formulæ given in Prof. Thompson's book, be made self-regulating? I think I have proved in my last letter that it cannot. It is useless for Prof. Thompson to shelter himself behind his friends Profs. Ayrton and Perry. Whatever those gentlemen may have done or may not have done, it is certain that they did not write Prof. Thompson's book. I suppose he, as the author, is responsible for every line in the book. Now, I have shown him, by common sense arguments in my letter a fortnight ago, that a page or so in that book is hopelessly wrong. If he can refute my arguments I am ready to be convinced. But let me ask him not to refer me to page so-and-so and formula so-and-so of his book. One can prove almost anything by a skilful manipulation of algebra—I can hardly call it mathematics—but if a thing cannot be reconciled with common sense no amount of mathematical symbols will convince me. I have given you a logical sequence of common sense arguments. Let Prof. Thompson, if he can, take them up one by one and prove them wrong. If, instead of doing this, he persists in addressing you in the vigorous but somewhat irrelevant manner he has hitherto employed, or if he passes this letter over in silence, I shall take the liberty of adhering to the opinion expressed in my review, that his chapters on motors require considerable improvement before they can be of any practical use, and I shall not further trouble you.—Yours, &c., THE WRITER OF THE REVIEW.

MISTAKES IN ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my article on p. 347 of the present volume I particularly avoided committing myself to any particular theory of electricity, as I wished my remarks to be applicable to either theory. That there are two distinct kinds of electrification is simply an experimental fact. The two fluid theory accounts for this by assuming two distinct kinds of electricity; the one-fluid theory by assuming an excess or defect of electricity of one kind only. Personally, I decidedly prefer the latter, as being simpler; but I am not aware of any objection that can be brought against the two-fluid theory except its want of simplicity.

In reply to Mr. Johnstone's question about the repulsion between two electrified pith balls, I believe the repulsion to be effected by the medium between them being thrown into a state of stress, for the only alternative would be a direct action at a distance of which I am unable to form any mental representation. I must apologise for taking up your space with a personal "confession of belief," but unfortunately Mr. Johnstone's questions were so worded as only to leave me a choice between doing this and leaving them unanswered.

If we understand by "a substance" whatever occupies space, I do not think there is any experimental evidence to show that electricity is not "a substance." By matter we usually understand "a substance," which has inertia and the property of self-attraction according to the Newtonian law. The latter property is certainly not possessed by electricity, and there is no experimental evidence which would lead us to believe that electricity has inertia.—Yours, &c,

G. W. VON TUNZELMANN.

ELECTRIC v. OIL LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A letter has appeared in one of your contemporaries on the above subject on the mis-quotation of some remarks made by me during the discussion on the recent paper at the Society of Arts. As the matter is of considerable public interest may I be permitted to lay before your readers what I really did say, and supplement this by my reasons, which, owing to the lateness of the hour, I was unable to give at the time of the discussion.

Following Mr. Wigham, who said gas could easily have beaten the electric light if he had been allowed to exhibit his double quadri-form of arrangement, I said that the comparative tables of cost given in Mr. Edwards's paper on lighthouse illuminants were hardly fair to the electric light, as they were made out on the supposition that an electric light of enormous candle-power, twenty times as powerful as that given by the 108 ring gas burner, must be used at all times, whether such an enormous light be required or not. I said that by proper arrangement an electric light could be furnished for lighthouse purposes which could be easily adjusted so as to give a sufficient light for ordinary clear weather, but which could be increased to any desired extent up to and even exceeding the enormous lights shown at the

Digitized by Google

Foreland, and that the result of this modification would be, that whereas the lighthouse illuminants report shows that the electric light costs two and a half times as much as oil does, it need only cost one and a half times as much as oil. The report on lighthouse illuminants to which I refer estimates the cost of an electric light station with single light, having double power for fogs, at £17,749, and the cost of maintenance at £1,927 per annum, whereas the corresponding figures for an ordinary first order oil lighted tower are £8,064. 18s. 3d., and maintenance £724. 4s. 7d. per annum. I propose to reduce the maintenance of the electric lighting station from £1,927 to £1,100 first, by providing for ordinary lighting in clear weather a group of fourteen 50 candle-power incandescent lamps, arranged in a close cylinder and not occupying a greater space than the present Douglass six-wick burner. For thick weather I propose to substitute a powerful direct current arc light, the full advantage of which could be best obtained by using a catoptric arrangement instead of the dioptric one hitherto employed for alternating current lamps. This catoptric arrangement would necessitate a revolving or partly revolving light, and as electricity is most likely to be used on headlands or the main land the beam need not revolve or oscillate through the entire circle. I know there is no difficulty in working out the practical details of such an arrangement as I have here briefly sketched out. The electric current for the incandescent lamps or for the large arc lamps can be supplied with the greatest certainty and steadiness from accumulators, which could be charged by a comparatively small combined steam engine and boiler, or, where gasworks are accessible, by means of a gas engine. In this way the extremely heavy charges of £800 a year for wages, coke, oil, and carbons, as estimated in the report, might be reduced fully one-half. The first cost of the plant, hence the charge for depreciation and renewals, would be greatly reduced. I will not occupy more of your valuable space by going into details. I think I have said sufficient to show that a strong case may be made out for the economy as well as the efficiency of electricity employed as a lighthouse illuminant.—Yours, &c.,

R. E. CROMPTON.

Mansion House-buildings, London, E.C., 1st April, 1886.

PARALLEL DISTRIBUTION BY TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Although we consider the newspaper discussion in reference to Messrs. Zipernowsky, Deri and Blathy closed as far as we are concerned, we cannot allow the claims described in their letter of the 18th ult. to pass without protest, and we declare for the last time that we shall not allow anyone to employ secondary generators or transformers of any model or under any conditions for the purpose of distributing electrical energy.—Yours, &c,

L. GAULARD,
J. DIXON GIBBS.

18, Warwick-street, Regent-street,
London, April 7th, 1886.

ELECTRICAL GOVERNORS FOR CONTROLLING THE SPEED OF MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The electrical governor for controlling the speed of motors which is figured and described on page 407 of the last number of your journal is similar to those employed in the motors which drive the transmitters of my type printing apparatus, and were exhibited at the Crystal Palace Electrical Exhibition by the Exchange Telegraph Company long before the date of Prof. Jenkin's patent.—Yours, &c.

F. HIGGINS.

THE DIGNITY OF SCIENTIFIC DISCUSSION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter on this subject in your last week's issue is, I think, a little hard on the members of the Society of Telegraph Engineers, and still harder on the Society itself. Scientific discussions should, no doubt, always be dignified; but we know very well they are not so invariably, any more than are theological or political discussions when opinions are strong and tempers warm. If the society in question is exceptional in any way, it is chiefly in being peculiarly tolerant of the idiosyncrasies of its members and visitors. This amiable weakness is at all events better than dulness. Then, again, the discussions, although ostensibly scientific, are not on all occasions really so; and when the subject is closely associated with the pockets of promoters, advisers, or directors—or inventors who hope to become such—it is not to be expected that the unruffled solemnity of a judicial assembly, wholly impartial and disinterested, will be rigorously maintained. I often enjoy my evening at this society, rarely at any other.—Yours, &c.,

QUIZ.

7th April, 1886.

OLD SPECIFICATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is a copy of a curious specification, dated 1872, that I happened to come across during a perusal at the Patent Office, and which may interest your readers:—

"My invention relates to the employment of an electrical conductor, fixed in the inner soles of boots, shoes, or slippers, or in clogs, for the purpose of driving away diseases, preventing epidemics, fever, small pox, or other contagious diseases, and dispelling noxious vapours.

"The electrical conductor is made of small, thin oblong pieces of zinc fixed in the upper soles of boots, shoes, or slippers, or in clogs. One of these oblong pieces of zinc is fixed in the front part of the upper sole, and the other in the heel part, being distinct one from the other. Copper or silver wires are placed lengthwise, and in rows, on the zinc pieces, and rest on them. The wires being in contact with the zinc cause an electrical current to be set up, and the electricity emanating from the body escapes by the wires which pass through the sole, coming out at the toe and heel respectively of the boot, shoe, slipper, or clog, thus producing a preventive force, and gradually and silently discharging from the body any excess of electric fluid, and causing a healthy action in a mild and continuous form."

The lady who filed the above has evidently not experienced the unpleasant consequences of completing a circuit through the sole of one's boot by way of an obtrusive nail.—Yours, &c.,

N. G. T.

4, Queen Victoria-street, London, E.C.,
April 2nd, 1886.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I promised to write to you on the subject of air in the lungs being the source of the supply of electricity in the human body, but before entering on this subject it is necessary to refer to some facts which throw light on the nature of electricity, and establish the accuracy of the conclusion I drew from the results of experiments on electricity which you published in 1882 (Vol. IX., page 63), namely, that electricity is a kind of matter which, although it does not gravitate, yet it seems to be the medium through which the law of gravitation acts on common matter.

1. Prof. Dewar has proved that oxygen gas is a transparent colourless fluid when exposed to a temperature of −130°C., and under a pressure of between 80 and 100 atmospheres, and also that liquid oxygen does not act on sodium, potassium, phosphorus, hydrogen, and other reagents.

2. MM. Hautefeuille and J. Chappius proved by experiments that ozone at the temperature of −23°C., and under a pressure of 75 atmospheres, is a liquid of azure blue colour.

3. All the modern books on chemistry assert that ozone is condensed oxygen.

4. Prof. Dewar found that the low temperature of −130°C. and presence of 80 to 100 atmospheres was incapable of con-

Digitized by Google

densing oxygen into ozone. Therefore something still more powerful is required in order to condense oxygen into ozone.

5. According to all modern books on chemistry, three volumes of oxygen gas are condensed into two volumes by their conversion into ozone, namely, that "ozone is oxygen existing as a triatomic molecule." Is this the truth? Yes; but it is not the whole truth. It takes something more than oxygen to make ozone; but this something is not allowed to have an existence according to books on chemistry.

6. When a frictional electric machine is set in motion the peculiar smell which arises is caused by the free electricity acting on the oxygen of the air, and converting it into ozone. And when scientists wish to make ozone in considerable quantity they pass oxygen gas through a tube which is kept electrified positively, namely, at that which is called a high potential, and the gas which goes in at one end of this tube as oxygen comes out at the other end in the form of ozone. In other words, a supply of electricity is required to condense oxygen into ozone.

7. If ozone gas be shaken within a glass vessel containing some powdered glass the electricity which the oxygen had absorbed to convert it into ozone leaves the ozone and goes into the powdered glass, and the ozone expands into and becomes oxygen gas. This process of making a portion of oxygen gas to alternately condense into ozone and again expand back into oxygen by alternately adding and subtracting the necessary quantity of electricity, may be carried on indefinitely; in other words, we can make ozone synthetically by adding an element to oxygen, and we can decompose ozone analytically by subtracting the said element. Yet, according to all the books on chemistry hitherto published, the element in question is not granted to have any existence. It is looked upon as being merely a mathematical quantity.

8. Look, now, at the enormous difference there is between oxygen gas condensed into ozone by means of electricity and oxygen gas converted into a liquid by the low temperature of $-130°$ C., and a pressure of from 80 to 100 atmospheres. The oxygen condensed by the means of adding electricity acts with enormously increased powers on all the ordinary reagents, and it acts so powerfully on such substances as vulcanised india rubber that if a tube of it be used to pass ozone gas through, the ozone soon destroys the tube; but oxygen alone cannot do this, and when oxygen is condensed into the liquid state by low tempararture, combined with enormous mechanical pressure, it loses all its power to act on the common reagents on which it acted so well when in the gaseous state. Why is this? When oxygen is condensed into ozone it is by means of electricity added to it; whereas when oxygen is converted into a liquid by low temperature and great pressure there is good reason to believe that the amount of electricity which the oxygen held in the latent form, while it was in the gaseous state, is crushed out of it in order that the oxygen might go into the liquid state, and that it is the reduced quantity of electricity within the liquid oxygen which makes it incapable of acting on the common reagents. Although it is undoubtedly the extra amount of electricity which becomes latent within oxygen and converts it into ozone, and gives the latter the increased power of acting on reagents, yet scientists will not admit that ozone is a compound of electricity and oxygen. Their theory which asserts that electricity is a nonentity is contradicted by the foregoing facts.

Maxwell wrote in his "Elementary Treatise on Electricity," page 8, "The analogy between temperature and potential must not be assumed to extend to all parts of the phenomena of heat and electricity." . . . "We must remember that temperature corresponds to a real physical state, whereas potential is a mere mathematical quantity, the value of which depends on the point of reference which we may choose. To raise a body to a high temperature may melt or volatilise it. To raise a body, together with the vessel which surrounds it, to a high potential produces no physical effect whatever on the body."

Is this true? In order to convert oxygen into ozone, the tube through which the oxygen passes requires to be kept at a high electric potential, and it is because it is so kept that the oxygen passing through the tube absorbs electricity, and the oxygen is thereby converted into ozone, which fact is the very opposite of Maxwell's statement, that "a high electric potential has no physical effect on the body," the oxygen.

Although electricity may not gravitate, yet it has the power of causing common matter, such as oxygen, to cohere and condense so that three volumes of oxygen are crushed into two volumes, which we call ozone.

There is another interesting matter in connection with this subject. When MM. Hautefeuille and Chappuis attempted to condense ozone gas into the liquid form, they found that the ozone exploded in the glass tube they were condensing it in, when the temperature was allowed to rise higher than $-23°$ C., and at the time the explosion occurred a flash of yellowish light appeared within the tube. These scientists did not attempt to explain these phenomena; but there can be only one cause for the explosion, namely, the sudden decomposition of the ozone. Its latent electricity having suddenly left it, the two volumes of ozone would instantly become three volumes of oxygen, hereby producing the explosive force. Now arises the question, What induced the latent electricity to leave the ozone? As the rise of temperature was the primary cause of the explosion, it must have been the increased quantity of heat within the tube which attracted the latent electricity and took it away from the ozone, and, if so, then we know that it must have been the union of the extra heat with the latent electricity which produced the flash of light within the tube.—Yours, &c.,

JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, April 1, 1886.

THE COMPANIES AND LORD RAYLEIGH'S BILL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is a copy of a letter sent by me to those interested in Electric Light Work:—

Mansion House-buildings, London, E.C.,
April 1, 1886.

DEAR SIRS: No doubt your attention has been called to *The Times* leading article of March 29 on the subject of Lord Rayleigh's Bill to amend the Electric Lighting Act. In that article several statements are made which in my opinion give an entirely false idea of the present position of the electric lighting industry in this country.

At the present moment I think that everyone in the trade should do what he can to assist to strengthen Lord Rayleigh's hands. I, for one, wish to do so by giving him trustworthy information as to the present position of the trade.

I am aware that some of the questions put below are of a somewhat delicate nature. I therefore leave it to you to answer them or not, as may suit the convenience of your firm, it being understood that my sole object in asking for this information is to use it for the benefit of the trade. Bearing this in mind, I should be obliged, if you think fit, to answer the whole or part only of the following questions:—

1. Has your business connected with electric lighting and electric transmission of power increased during the eighteen months ending April 1, 1886?

2. If so, what proportion of your orders has been for foreign countries and the colonies, and what proportion for home consumption?

3. What number of hands do you consider find employment at your works, or in the pay of your agents in the United Kingdom in the work of electric lighting and transmission of power?

4. Do you consider that the relaxation of the present legislative restrictions on house to house electric lighting would result in an increase of general business?

5. Do you think it advisable that the trade should act as a united whole to protect its interests in the Committee Rooms of the Houses of Lords and Commons by employing counsel, &c.?

6. If so, will you name the maximum amount you are prepared to give towards a guarantee fund to meet the necessary expenses?

I remain, yours faithfully,

R. E. CROMPTON.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 415.)

The same objection need not apply to Clausius' theory, for substituting the value of f belonging to his theory, the kinetic energy equals

$$(\tfrac{1}{2}m + \alpha e^2)q^2 + (\tfrac{1}{2}m' + \beta e'^2)q'^2 + \kappa ee'\frac{qq'\cos\epsilon}{r},$$

so that the kinetic energy will be always positive if

$$(\tfrac{1}{2}m + \alpha e') \quad (\tfrac{1}{2}m' + \beta e'^2) > \frac{\kappa^2 e^2 e'^2 \cos^2\epsilon}{4r^2}.$$

This condition will evidently be satisfied if

$$\alpha\beta > \frac{\kappa^2}{4},$$

and this relation does not involve the electrification. We cannot assume that we can make r so small that this condition is not satisfied, for r has a minimum value depending upon the shape and size of the electrified bodies. For example, if these are spheres, r cannot be less than the sum of their radii. On the other hand, α and β may be functions of the sizes of the electrified bodies, and the geometrical relations may be such that the condition written above must be always satisfied.

Physical reasons why the force between two electrified bodies should depend on their velocities and accelerations.

If we assume Maxwell's hypothesis that a change in the electric polarisation produces the same effect as an electric current, then we see that the kinetic energy of an electrified body must be different from the kinetic energy of the same body moving at the same rate but not electrified. For let us suppose that we have an electrified body at rest, and consider the amount of work necessary to start it with a velocity q. It is evident that it will be greater than when it is not electrified, for when it is electrified and in motion the electric polarisation in the surrounding dielectric will be in changing, and so in addition to starting the body with a velocity q we have, if Maxwell's hypothesis be true, to establish what is equivalent to a field full of electric currents. The production of these currents of course requires work, so that more work is required to start the body with a velocity q when it is electrified than when it is not; in other words, the kinetic energy of a moving electrified body is greater than that of one not electrified, but under similar conditions as to mass and velocity. In fact in this case electricity behaves as if it possessed inertia.

In a paper published in the *Philosophical Magazine*, April, 1881, I have shown that the kinetic energy of a charged sphere of radius a and mass m moving at a velocity q

$$= \tfrac{1}{2}mq^2 + \tfrac{2}{15}\frac{e^2\mu}{a}q^2,$$

where μ is the magnetic permeability of the surrounding dielectric and e the charge of the sphere. If there are two spheres in the field, then I have shown in the same paper that the kinetic energy

$$= \tfrac{1}{2}mq^2 + \tfrac{2}{15}\frac{\mu e^2}{a}q^2 + \tfrac{1}{2}m'q'^2 + \tfrac{2}{15}\frac{\mu e'^2}{a'}q'^2 + \tfrac{1}{3}\frac{\mu e e'}{R}qq'\cos\epsilon,$$

where corresponding quantities for the two spheres are denoted by plain and accented letters. We see from this expression that the forces between the spheres are exactly the same as those given by Clausius's formulæ. It would not, however, be legitimate to go and develop the laws of electro-dynamics from this result in the way that Clausius does, as Clausius's conception of an electric current does not accord with that of the displacement theory. We may remark that in this case the part of the kinetic energy due to the electrification is always positive.

On theories which are based on dynamical considerations, but which neglect the action of the dielectric.

F. E Neumann* was the first to develop a theory founded on the principles of the Conservation of Energy. His theory was based upon the assumption that two elements of circuit ds, ds', traversed by currents ι, ι' possess an amount of energy equal to

$$A^2\frac{\iota\iota'\cos\epsilon}{r}ds\,ds',$$

where A is a constant which depends upon the unit of current, r is the distance between the elements, and ϵ the angle between their directions. F. E. Neumann showed that this assumption leads to the same law of force between two closed circuits as that given by Ampère, and also explained by means of it the induction of electric currents. Von Helmholtz† has investi-

* "Die mathematischen Gesetze der inducirten electrischen Ströme," *Schriften der Berliner Academie der Wissensch*, 1845.

† "Crelle," LXVII., p. 57; *Gesammelte Werke*, Vol. I., p. 545.

Digitized by Google

gated the most general expression for the energy possessed by two elements of current which is consistent with the condition that the force between two closed circuits should be the same as that given by Ampère's theory. We shall consider this theory in detail, as it includes all theories of this class, and we shall wish to refer to it when we come to discuss the relative methods of the various theories. Von Helmholtz begins by showing that the most general expression for the energy of two elements of circuit consistent with Ampère's laws for closed circuits is

$$\tfrac{1}{2}\frac{A^2 \iota\iota'}{r}\{(1+k)\cos\epsilon + (1-k)\cos\theta\cos\theta'\}\,ds\,ds',$$

where θ and θ' are respectively the angles ds and ds' make with the line joining the elements, k is a constant, and the other symbols have the same meaning as before.

Let us call this quantity T; then we know that T denotes the existence of a force dT/dr or

$$-\tfrac{1}{2}\frac{A^2\iota\iota'}{r^2}\{(1+k)\cos\epsilon + (1-k)\cos\theta\cos\theta'\}\,ds\,ds'$$

along r, and a force $-dT/rd\theta$ at right angles to r in the plane of ds and r, and in such a direction that it tends to diminish θ; this force equals

$$\tfrac{1}{2}\frac{A^2\iota\iota'}{r^2}(1-k)\left(\sin\theta\cos\theta' + \cos\theta\sin\theta'\frac{d\theta'}{d\theta}\right);$$

and since

$$\frac{d\theta'}{d\theta} = \cos\eta,$$

where η is the angle between the plane containing r and ds and that containing r and ds', the transverse force

$$= \tfrac{1}{2}\frac{A^2\iota\iota'}{r^2}(1-k)\{\sin\theta\cos\theta + \cos\theta\sin\theta'\cos\eta\}.$$

We see that these forces will coincide with those assumed in Kortewegs's theory if the quantities a, b, c, d, which occur in that theory, have the following values :—

$$a = -A^2$$
$$b = -\tfrac{1}{2}(1-k)A^2$$
$$c = \tfrac{1}{2}(1-k)A^2$$
$$d = \tfrac{1}{2}(1-k)A^2.$$

So that whatever be the value of k, these quantities satisfy the condition

$$2a + b + c - 2d = -3A^2.$$

According to Stefan, it is necessary if two circuits have a potential that

$$2a + b + c - 2d = 0.$$

But Stefan did not consider the couple exerted by one element of circuit on another. The couples acting on the element ds' will be as follows. There will be a couple tending to increase θ', *i.e.*, a couple whose axis is at right angles to both ds' and r, equal to $dT/d\theta'$, *i.e.*, to

$$\tfrac{1}{2}\frac{A^2\iota\iota'}{r}\{(1+k)\sin\theta\cos\theta'\cos\eta - 2\cos\theta\sin\theta'\},$$

and another couple tending to increase η, *i.e.*, a couple whose axis is along the line joining the elements equal to $dT/d\eta$, *i.e.*, to

$$-\tfrac{1}{2}\frac{A^2\iota\iota'}{r}(1+k)\sin\theta\sin\theta'\sin\eta.$$

We see that these will agree with the couples in Korteweg's theory of

$$f = -\frac{A^2}{r};\quad g = -\tfrac{1}{2}A^2\frac{(1+k)}{r};\quad h = \tfrac{1}{2}A^2\frac{(1+k)}{r}.$$

Let us return to the consideration of the energy of the circuits, and suppose that, instead of currents flowing along linear circuits, we have a distribution of them throughout space. If u, v, w be the currents in the element dx, dy, dz, then the part of the energy contributed by this element will be

$$-A^2\{Uu + Vv + Ww\}\,dz\,dy\,dz,$$

where

$$U = \tfrac{1}{2}\iiint\left\{(1+k)\frac{u}{r} + (1-k)\frac{x-\xi}{r^2}\{u(x-\xi) + v(y-\eta) + w(z-\zeta)\}\,d\xi\,d\eta\,d\zeta\right\}$$

with symmetrical expressions for V and W, where

$$r^2 = (x-\xi)^2 + (y-\eta)^2 + (z-\zeta)^2.$$

We may write the expressions for U, V, W in the form

$$U = \tfrac{1}{2}(1-k)\frac{d\psi}{dx} + \iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta$$

$$V = \tfrac{1}{2}(1-k)\frac{d\psi}{dy} + \iiint\frac{v}{r}\,d\xi\,d\eta\,d\zeta$$

$$W = \tfrac{1}{2}(1-k)\frac{d\psi}{dz} + \iiint\frac{w}{r}\,d\xi\,d\eta\,d\zeta,$$

where

$$\psi = \iiint\left(u\frac{dr}{d\xi} + v\frac{dr}{d\eta} + w\frac{dr}{d\zeta}\right)d\xi\,d\eta\,d\zeta$$

If u, v, w are the components of the ordinary conduction current, e the volume density of the free electricity, then

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = -\frac{de}{dt};$$

and if l, m, n, be the direction cosines of the normal to a surface at which the currents become discontinuous, σ the surface density of the electricity on this surface, then

$$l(u-u^1) + m(v-v^1) + n(w-w^1) + \frac{d\sigma}{dt} = 0.$$

Remembering these equations, ψ may be transformed into

$$\iiint r\frac{de}{dt}\,dx\,dy\,dz + \iint r\frac{d\sigma}{dt}\,ds;$$

or if ϕ denote the electrostatic potential of the free electricity, we see

$$\psi = -\frac{1}{2\pi}\iiint\frac{1}{r}\frac{d\phi}{dt}\,dx\,dy\,dz.$$

Substituting the value of ψ we find

$$\nabla^2 U = (1-k)\frac{d^2\phi}{dx\,dt} - 4\pi u,$$

$$\nabla^2 V = (1-k)\frac{d^2\phi}{dy\,dt} - 4\pi v,$$

$$\nabla^2 W = (1-k)\frac{d^2\phi}{dz\,dt} - 4\pi w.$$

We also see that

$$\frac{dU}{dx} + \frac{dV}{dy} + \frac{dW}{dz} = -k\frac{d\phi}{dt}.$$

In order to get the equations connecting the electromotive force with the variation of the electrodynamic potential, Neumann made use of Lenz's law, and assumed that, since by that law the electromotive force tending to increase the current in an element of circuit moving with a velocity w in the direction s would be of the same sign as

$$-Xw,$$

where X is the force along s on the element per unit of length per unit of current flowing through it, it was actually equal to this quantity multiplied by a constant c, *i.e.* to

$$-cXw;$$

but if $Ti\,ds$ be the energy of the element of current whose length is ds, and current strength i,

$$X = \frac{dT}{ds},$$

and

$$w = \frac{ds}{dt};$$

so that the electromotive force per unit of length of the element

$$= -c\frac{dT}{ds}\frac{ds}{dt}$$

$$= -c\frac{dT}{dt}.$$

Von Helmholtz has shown that it follows from the principle of the Conservation of Energy that if the energy in the elements dx, dy, dz, traversed by currents u, v, w, be

$$A^2(Uu + Vv + Ww)\,dx\,dy\,dz,$$

then the components of the electromotive force parallel to the

Digitized by Google

axes x, y, z respectively, due to the variation in the electrodynamic potential, will be

$$-A^2\frac{dU}{dt}, \quad -A^2\frac{dV}{dt}, \quad -A^2\frac{dW}{dt};$$

the free electricity produces an electromotive force whose components are

$$-\frac{d\phi}{dx}, \quad -\frac{d\phi}{dy}, \quad -\frac{d\phi}{dz},$$

so that the total electromotive force parallel to x, y, z

$$= -\frac{d\phi}{dx} - A^2\frac{dU}{dt}.$$

(To be continued.)

CANTOR LECTURES.

Professor Forbes delivered the first of a series of six elementary lectures on Electricity in the rooms of the Society of Arts, John-street, Adelphi, on Saturday last. He said: The work of the philosopher in studying the phenomena of nature is accomplished by the aid of either observation or experiment. In the science of astronomy we can only wait, watch, and observe the signs and symbols which nature makes to us, and interpret the language in which she speaks. In the realm of electricity, however, we cannot depend much upon observation; and it is only in the laboratory, by patient experiment, that most of the secrets of electricity are evolved. With the lightning flash, the aurora, and the attraction of the compass needle, almost the whole list of facts which can be learned in connection with electricity and magnetism have been enumerated; and it is in the laboratory that we must learn how varied are the phenomena, and how fruitful is the application of this science, while at every step we find a new pleasure in receiving answers to our questions. The highest delight of the true philosopher is in seeking out new facts, and the chief charm in electricity to the true student is in grasping the innumerable phenomena which are presented to his sense, and co-ordinating and arranging those facts until he finds that a few general laws govern the whole of the diverse forms under which this protean agent is seen to manifest itself. It will be my object in this course of lectures to lay before you simply the fundamental phenomena of this comparatively new but useful servant of ours, and to demonstrate experimentally the identity of the agent, however diverse may be the operations which it has accomplished.

It was my intention when first asked to give this course of lectures to drop our old friend frictional electricity altogether, but on fresh consideration I found it was impossible to give what I wanted—that is, though it may be sketchy, an account of all the important fundamental principles which govern the science. It is impossible for us to realise what we mean by potential and electromotive force unless we study frictional electricity, and it is by means of this high tension electricity that we are able to study the peculiarities of those insulating materials which we use for telegraph cables, which are required in the highest degree in the practical applications of electric lighting and transmission of power. It is only by means of high tension electricity that these phenomena can be properly studied, and that we can appreciate what is the part played by the insulating medium when electrical phenomena are being mainfested. I shall not delay long in showing you some of the very elementary principles which are necessary to make the survey of this part of the subject tolerably clear. I shall show first what is a well-known principle—a long-known power—namely, that, when I rub two materials together, such as a piece of glass and a piece of silk, they attract each other. Here I have a piece of silk suspended to the retort stand; I rub it briskly with a piece of glass, and you notice that it attracts the silk to one side, and that the brisker I rub it the more complete is the attraction. Not only is it so when it is in contact with the silk, but it will even attract it from a little distance. This is the first phenomenon that has to be grasped in electricity—namely, that two bodies when rubbed together will attract each other. I might take other materials and illustrate the primary fact, attraction, in a variety of different ways. This is easily done in many ways which are probably familiar to all of you. Here is a piece of sealing wax, and when I rub this with cat's skin I show that there is attraction between the sealing wax and the cat's skin. But I will now demonstrate to you that it is able to attract another body. I have here a piece of gilt paper rolled up in a ring, and the sealing wax will be seen to attract that gold leaf, which will be made to run over the table in whichever way I choose. [Experiment shown.] There are many other experiments which might be shown in the same way. I will now introduce to your notice this most delicate instrument which we have for detecting the presence of electricity, which is called a gold leaf electroscope. When we say a body is electrified, we merely mean that it has that peculiar property of attracting which I have shown you just now. You must not imagine that there is a material substance residing on the sealing wax or the glass rod when it is electrified, you must simply understand that it possesses this unusual property, this electrical condition. When sealing wax possesses that unusual condition —when we say it is electrified—it has the power of communicating that condition to another body which is touched with it, and this can be shown when we touch the electroscope which is before you. The result will be seen in the repulsion of the leaves of the electroscope. [Experiment.] Now this is a new fact. Here we have two gold leaves hanging within a metal jar, and they are both electrified by the same substance and they repel one another. This is the first case of repulsion that has come before you. We should find that, as a rule, there are two different kinds of electrification, and I will not delay long to point this out. At the present moment you see that the gold leaves are repelling each other with slight force. You will see, if I approach this sealing wax towards them they tend to close in. If I withdraw the sealing wax they spread out again.

With an electrified glass rod a very different thing takes place. I rub the glass rod briskly, and I approach it towards the gold leaves, and they diverge still further—that is to say, the rubbed sealing wax tends to destroy the electrification of the gold leaves; the rubbed glass rod tends to increase it. This shows us a difference in the quality of the electricity, which is developed with the sealing wax and the glass rods. And now we have found two things: that there is sometimes attraction, and there is sometimes repulsion. I pointed out to you that when the glass rod and silk were rubbed together there was always attraction, and I may state generally that when two dissimilar bodies are rubbed together there is always attraction. But we have also seen that the two gold leaves when electrified with the same kind of electricity repel each other, and in this way we are led to the general law that similar bodies similarly electrified repel each other, and bodies electrified in a different way from each other attract each other. And this, then, is what we arrive at—that if we take any two materials and rub them together the one will be electrified in one manner and the other electrified in another manner, so that they can attract each other; but if a single electrified body be taken and caused to touch different bodies the latter will repel each other, because they are electrified in the same way. Now this enables us to classify all the different bodies in a regular scale, and I have a table at my side here [A list of various substances exhibited] which is arranged in such a manner that if you rub any of these two substances together—for example, the one which is the highest on the list—it will be what we call positively electrified, and will be analogous in its behaviour to the rubbed glass, but the one which is lowest on the list will be negatively electrified in the same manner as rubbed sealing wax is. The list comprises cats' fur, polished glass, silk, woollen stuff, feathers, wood, paper, shellac, and rough glass.

Now, I draw your attention to the fact that the order in this list does depend on the character of the substance and the nature of the surface. In that table you will see that rough glass is put at the bottom and polished glass is put near the top. Now, I have a piece of glass which is half rough and half smooth. I rub these with my sealing wax as before. According to the table which we have there the smooth-polished glass comes before the silk, and therefore it should affect the gold leaves in the manner represented by positive electrification. So when I approach it thus the leaves converge. [Experiment.] I now reverse the end of the rod and rub the roughened glass, and you will see, according to the table, that the roughened glass will be negative, and the opposite of attraction will take place on the electroscope. If I rub it on the fur of the cat we shall get the effect better—so. This is a peculiarity of the surface, and it is one which we find at different stages of our investigation. We find that the surface has an influence on the character of the electrification. Thus we find that a black ribbon rubbed with a white ribbon is negative to it; we discover that a hot piece of cork rubbed against a cold piece of cork is negative to it. I point out to you the fact that in these cases where the fact of surface comes in, the material which is the best radiator of heat becomes negative to the one which is the worst radiator of heat. Black silk radiates more than white silk, a rough surface more than a smooth surface, and is negative to it. I give you this fact merely as an aid to your memory in view of what I shall have subsequently to tell you.

Hitherto I have dealt with the electrification of materials which we call insulators, which do not conduct electricity readily. If I rub a piece of brass with the cat's skin it will be found to have no influence whatever on the electroscope; but it is not because electricity is not generated in the brass; the reason is that the brass is able to conduct the electrical condition through my hand, and so over the surface of my body to the earth; and if I put the brass on a piece of sealing wax which does not conduct the electricity freely, then we shall be able to see when rubbed with the cat's skin that there is a development of electricity as shown by the divergence of the gold leaves. [Experiment shown.] I simply mention this fact, which has been carefully studied by experimenters, that we find the law of attraction between two bodies so electrified varies inversely as the square of the distance—that is, it follows the same laws as gravitation. We are accustomed to say when we electrify a body in any of these manners that the two substances which are rubbed together, after the rubbing, have different electrical potentials. I will come to speak of that presently, and a thorough understanding of it will help us vastly in our more advanced stages. I merely here remark that I can obtain a very high difference of potential by means of such machines as have been constructed, such as this apparatus, which is the well-known electrical machine of Mr. Wimshurst, by means of which we are able to get vivid sparks. I have here a very large multiple plate machine which has been kindly constructed for illustrating these lectures by Mr. Wimshurst. He has spent a great deal of time in improving the construction of machines for generating electricity. Two or three weeks ago another gentleman and myself were visiting his house, and we were struck with a magnificent machine which he had completed, which gave a larger quantity of electricity, I may say, than any machine that has hitherto been constructed. A sigh escaped me when I thought I could not produce that machine before the present audience, and without saying a word to me Mr. Wimshurst, immediately on our departure, set to work and manufactured this machine—[showing it]—which could be easily transported from his house, and it shows the outcome of a fortnight's work taken out of sleep hours. It is an act of kindness for which I cannot too heartily thank that gentleman. There is a word which I have used to you just now, and which is being continually used in connection with the application of electricity, and that is the difference of electrical potential. And this is a fitting time to say something about it. As I have been telling you, these two bodies when rubbed together

Digitized by Google

acquire a difference of potential. What do we mean by this expression? It is a comparatively new one in scientific language, but one of the greatest importance. We know that force of gravity gives velocity to a falling body, and the body acquires energy of motion. When a body is raised from the floor on to a table it also acquires energy, although it is not in motion, because it has the power of dropping back again to the floor, and so doing work. How are we to express the energy that exists in a ball, for example, when it is on a table? It has the potency of doing work. It has what Newton called potential energy, and that expresses freely what we mean. Now, suppose a ball be thrown up into the air; at starting it gains energy—energy of motion; but gradually the energy of motion disappears and its velocity gets less and less, until at the top of its flight it has no motion at all. The whole energy of motion with which it started has been converted into energy of position, and the grand principle of the conservation of energy tells us that at any moment in the history of the universe the energy in it is the same. And this is an illustration of the conservation of energy, that the sum of the energy of motion and the energy acquired by its position is constant in the case of the ball. You see, then, what we mean by energy of position, and the energy of position is identical with what we speak of as potential energy. Now, if I have a piece of sealing wax negatively electrified, and a piece of cat's skin positively electrified, and then take any substance charged with positive electricity, and carry it from the sealing wax, which attracts it, to the cat's skin, which repels it, I am obliged to do work, just as I am obliged to do work in raising a weight from the floor on to a table; and what I mean by the difference of potential between the cat's skin and sealing wax is simply the work which I should have to do on a ball in lifting it from the sealing wax to the cat's skin. That is simply what is meant by the difference of potential between two bodies. Various instruments have been devised for measuring the difference of electrical potential. The gold leaf electroscope which we use, as being more handy and convenient in a room, does not actually measure the difference of potential, but merely serves to indicates whether there is a great difference of potential or not. The most sensible and most exact instrument we have is what is known as the quadrant-electrometer of Sir Wm. Thomson, and I believe I shall be able to show you that delicate instrument.

Hitherto I have been speaking to you about electric forces—the forces with which two electrified bodies attract or repel each other; and these forces are what we all can thoroughly understand as being forces, because we see their effects in the motion of material bodies. I am now going to bring before your notice different kinds of force which is not readily called force in the Newtonian sense of the word. The force which I am going to speak of now is usually called by the name of electromotive force. Newton called force that which causes or tends to cause motion in a body. When we have seen these attractions and these repulsions we have seen motions produced in a body. When gravity is acting on a heavy body it is tending to produce motion, although the tendency is not allowed to come into effect. In all cases of force, as Newton intended the word force to be used, motion is produced, or tended to be produced, in a body. With electromotive force this is not the case. Electromotive force is a tendency to produce a change in the electric condition of a substance. I will try and show you the production of this kind of force by its action upon a conductor. I have here two balls so connected together that they make one continuous conductor. If I were to take one or other towards the electroscope it would not show any signs of electrification; but now, when I rub this cylinder with the silk it becomes electrified in the same way. But I will not touch them, I will bring them into the neighbourhood of the two—so. This glass is positively electrified, and I say it attracts negative electricity towards itself, and repels positive electricity away. It is acting upon the electrical distribution, and I will now separate these balls, and I have no doubt that the electroscope will show that they are charged, the nearer ball with negative and the further with positive electricity. [Experiment shown.] Thus we see not only can electrification produce visible tangible effects in the way of motion on a material body, but it is able to create a motion of electricity; that if the body be positively electrified, it is able to attract the negative electricity towards itself, and to repel the positive electricity to the most distant part of the substance.

I will now show you one or two applications of this principle of induction as it is called. The first illustration may be given by showing the influence on the gold leaf electroscope. If I rub the sealing wax once more and electrify it, the sealing wax becomes negatively electrified. If I cause it to approach the electroscope the positive electricity will be attracted to the sealing wax, the negative electricity will be repelled, as you see by the movement of the gold leaves. [Shown.] On removing the sealing wax the electromotive force is removed, and the electrification returns to its normal condition. Now, I will repeat the experiment in a slightly different way, and I will connect the gold leaves with the earth by means of my finger, so that the electricity which is repelled by the sealing wax may pass to the earth instead of to the gold leaves. [Experiment.] Now it has passed to the earth, and the positive electricity is attracted towards the sealing wax, and exists in the gold leaves and their attachments. I now remove the sealing wax, and the leaves diverge by reason of the charge of positive electricity which has thus been "induced" in them. When I take a pith ball, or any light material like that, and bring an attracting substance near it, the attraction which takes place is only due to induction. The negative sealing wax will draw positive electricity towards it, and repel the negative; the positive being nearest to the sealing wax is most attracted, and, therefore, we have attraction. But when once the electrification of th sealing-wax has been communicated to the pith balls they are repelled in the ordinary manner.

I will now show you several ways in which induction can be applied. First, let me show you the electrophorous. Here is a plate of resin. I will give it a few brisk rubs with the cat's skin; it is now electrified negatively. I now place on the top of it a metal disc, like this, which touches the resin on two or three points and takes off the electricity of these points. Now, the parts which were not in contact with the brass are negatively electrified and attracting the positive electricity towards the brass, and the negative electricity is repelled through my fingers to the ground. If I now lift this it ought to be charged with positive electricity—so. I will show you a thing which can be done by means of this electrophorous. [Experiment with Leyden jar.] Having once more charged it thoroughly, I can repeat the operation which I did just now, and I can go on a great number of times. This jar is all the time accumulating a greater charge. Thus, by means of going through this operation of induction and communication, in this way I am able to give a very considerable charge to that apparatus, which is called the Leyden jar. At present it is sufficiently charged to show you how electricity is accumulated, for I am able by that means to induce electricity to a great extent. I will demonstrate to you what that general principle has led up to in the past. It has led to the construction of machines of very great simplicity and probably of great utility in the future, although we do not see exactly at present what the applications may be.

The first actual machine of the kind which was made was what was called Nicholson's doubler, which is an automatic means of increasing the charge by induction. I will not delay here with this, but simply say that this instrument was invented in 1780, and this little instrument before you is the precursor—the one which has led up to the construction of this magnificent machine (Wimshurst's presumably) which produces marvellous effects, which I will presently show you. It takes a little time to charge itself. The peculiarity of Mr. Wimshurst's machines is that they do not give us much trouble; but he has made this one not to be able to charge itself very rapidly, and it may cause us a little delay. In the meantime I will show you this apparatus, which Mr. Wimshurst has constructed to show the principle of his machine. It consists of two glass discs or spheres that rotate in opposite directions upon a spindle, and these brass wires which you see carry any electricity which may be introduced across through the disc at one part of the circumference to another part of the circumference, and there is a continual mutual induction going on between the two discs; and so by means of these brass wires the electricity which may be introduced adds this effect to the two opposite sides of the disc, and there is a greatly increased effect, so that when the induction has taken place for a few seconds we see very vividly the quantity of electricity which is produced in this very pretty little instrument, which Mr. Wimshurst calls the "electrical sprinkler." [Experiments.] Here we have a very brilliant discharge. It is very seldom that such a quantity of electricity has been generated by a machine of this kind. This machine consists of eight plates arranged in a most favourable condition, according as it has been developed by Mr. Wimshurst, and this discharge which I am showing you just now is that which shows the greatest quantity of electricity in a given time. That is, not in the form of a spark, but it gives us the largest quantity of electricity that we can get. I will now connect two Leyden jars, and then you will see that we can get a totally different effect. Let me say in regard to these Leyden jars that by connecting the insides with one pole and the outsides with another, or something equivalent to that, that I am able to accumulate in this conductor a large quantity of electricity before it is able to escape to the other conductor. These Leyden jars, as they are called, are simply accumulators of electricity, and they accumulate the electric charge. I shall begin with the poles very close together, and now the electricity cannot pass across that distance between those poles until these acquire a certain difference of potential. Consequently, in this arrangement of the experiment, what we shall see is a pause during which nothing happens; then a flash across; then a pause; then a flash across; then a pause, during which the electricity is accumulating. [Experiment.] I limit myself to about six or seven inches spark, because I do not wish to press the experiment too far. There is an experiment which I am anxious to try, but which I have not perfect confidence in; but I am in hopes that I shall be able to show it later on. I shall strain this machine to its utmost limit, and the limit will not be the strength of the machine, but that of the Leyden jar, and we may possibly break one of these Leyden jars—indeed that is very likely to be the case, but it will show you the power of the machine.

(To be continued.)

ON A NEW FORM OF STEREOSCOPE.*

BY A. STROH.

Two optical lanterns are placed side by side, as for dissolving views. Two transparencies, photographed in the same manner as if intended for an ordinary stereoscope, are placed one in each lantern, and projected on a screen in such a position that they overlap each other as nearly as possible. The picture which is intended to be seen by the right eye may be placed in the right-hand lantern, and the other in the left.

Supported by suitable framework, and in the front of the two lenses of the lanterns, is a revolving disc, portions of which are cut away, so that during its revolutions it obscures the light of each lantern alternately, or, in other words, so that only one picture at a time is thrown on the screen. A continuous change from one picture to the other is thus obtained.

In the same framework, and in convenient positions for the observers, two pairs of eyeholes are provided, one pair on either side of the apparatus. Behind each pair is also a rotating disc, and these discs are connected by suitable wheel work or driving bands with the one previously mentioned, in such a way that the three discs rotate together, and at the same rate.

* Abstract of a Paper read at the meeting of the Royal Society, April 1, 1886.

The two last-named discs are also so cut that they will obstruct the view through the right and the left eyeholes alternately.

Finally, the connection between the three discs has to be so arranged that the time of obscuring the view through the right eyeholes or the left eyeholes shall coincide with the time when the light is shut off from the right or left lense of the lanterns respectively.

It is obvious that by this arrangement an observer can only see the picture projected from the left lantern with the left eye, and the one from the right-hand lantern with the right eye.

The rotation of the discs must be of such a rate, that the alternate flashes of the right and left pictures on the corresponding eyes follow in such rapid succession that the impression made by one flash does not diminish sensibly before the next flash on the same eye is received. The number of flashes for each eye which is required to produce an apparently continuous view, without any flickering effect, is from thirty to forty per second. As the discs are so cut as to produce two flashes for the right eye and two for the left in one revolution, they must consequently be kept rotating at a rate of from fifteen to twenty revolutions per second.

The rotation of the discs is effected by a driving wheel and band, worked by a crank handle at the back of the apparatus.

The perspective effect obtained by the above arrangement is very perfect, the image of each object standing out in solid relief. Considering that by this arrangement the two eyes never see at the same time, and that each eye views its picture after the other, it is interesting to find that the persistence of vision so completely bridges over the alternate interruptions to which it is subjected as to produce the effect of a continuous view.

The advantages claimed for this form of stereoscope are, that the pictures can be enlarged to such an extent as to appear equal, or even larger than the original objects from which they were taken; and that the eyes, in looking at the pictures, are not in any way subjected to strain by lenses, prisms, or reflectors, or by the difficulty which some persons experience in getting the two pictures to superpose. For each eye views its corresponding picture in exactly the same position it would see it in if it were looking at the original, since the two pictures are practically in the same place, which is not the case in any other form of stereoscope.

Although, with the apparatus as here described, only two persons can see the pictures at the same time, it would not be very difficult to construct it so as to be available for a greater number. The side discs above described only serve to control one pair of eyeholes each, but by making them larger they would serve for two pairs each, thus accommodating four observers. By increasing the number of discs the number of observers might be increased proportionately.

PHYSICAL SOCIETY.—March 27th.

Prof. W. G. Adams, Vice-President, in the chair.

Mr. A. R. Wright was elected a member of the society.

The Chairman read a letter from Dr. Alder Wright, secretary to the Tribe Fund Committee, in which reference was made to the scientific work of the late Mr. Alfred Tribe, and an appeal made for funds to aid in the maintenance and education of his family, which, owing to his early death, had been left in straightened circumstances.

The following communications were read:—"On an Arc Lamp Convenient for Use, with the Duboscq Lantern," by Prof. S. P. Thompson. The old Duboscq lamp, though working well with a series of Grove cells, is very unsuitable for use with currents from dynamos. Prof. Thompson has employed as a substitute in the Duboscq lantern a lamp commonly known as the Belfast arc lamp. The result is all that can be desired as regards steadiness and regularity. The "focussing"—that is the adjustment of the arc so that it shall remain unchanged in position—is effected by a wheel below the lantern, which is moved by hand.

"On a Modified Maxwell's Galvanometer," by Prof. S. P. Thompson. The galvanometer consists of a light frame of copper, upon which is a coil of wire. This is suspended between the poles of a horseshoe magnet, and a piece of soft iron is placed within the coil, but free from it, which concentrates the magnetic force between the poles. The coil is suspended by two silver wires, by which it is in connection with two binding screws on the base of the instrument. This galvanometer is extremely simple in adjustment and very dead beat. It has also the advantage of being affected to an inappreciable extent by neighbouring magnets and currents, with a current in its own coils. When no current is in it is of course quite unaffected. The reading is effected by the ordinary lamp, mirror, and scale arrangement.

"On the Expansion of Mercury between 0° and −39° C.," by Professors W. E. Ayrton and John Perry. On November 14, 1885, Mr. G. M. Whipple gave the society the results of the examination of thermometers down to the melting point of mercury. There was, however, no evidence as to whether the contraction of the mercury continued uniform, as the thermometers were only compared with mercurial ones. The authors have therefore examined this point, and have made a series of comparisons of a mercurial thermometer, lent them by Mr. Whipple, with a constant volume air thermometer, both immersed in a bath of frozen mercury which was allowed to gradually become warm. The result obtained was that no certain deviation from a linear law could be detected in the expansion of mercury when temperature was measured by the increase of pressure required to keep a volume of air constant. Hence temperatures down to −39°C. may be correctly measured by a mercury thermometer, the stem of which is graduated for equal volumes.

"On the Expansion produced by Amalgamation," by Profs. W. E. Ayrton and J. Perry. It has been accidentally observed by the authors that the amalgamation of brass is accompanied by great expansive force. If one edge of a straight thick brass bar be amalgamated, it will be found that in a short time the bar is curved, the amalgamated edge being always convex and the opposite concave. The authors imagine that a similar action may be the primary cause of the phenomena presented by the Japanese "magic mirrors." Japanese mirrors are made of bronze, and have a pattern cast upon the back, and although to the eye no trace of it can be discovered upon the polished, reflective surface, yet, when light is reflected by certain of these mirrors on to screen, the pattern is distinctly visible in the luminous patch formed. In a paper before the Royal Society they have shown that this is due to the polished side opposite the thinner parts of the casting being more convex than the others, a conclusion verified by the fact that the pattern is reversed when formed by a convergent beam of light. Such a condition of things would evidently result from a uniform expansive stress taking place over the reflecting surface, the thinner, and consequently the weaker, parts becoming more convex or less concave than the others. The authors have hitherto attributed this inequality of curvature to a mechanical distortion to which the mirrors are intentionally submitted during manufacture, to produce the general convexity of the polished surface; but they now think it possible that the use of a mercury amalgam in the process of polishing may have an effect in the production of this inequality of curvature.

THE ELECTRIC LIGHTING ACTS.

Yesterday, at a large meeting of the Association of Municipal Corporations, held at Westminster Palace Hotel, the Mayor of Salford in the chair, the three Electric Lighting Bills now before the Lords were considered, and the report of the Law Committee thereon read and adopted. Sir George Morrison, town clerk of Leeds, explained that at a joint meeting of the Parliamentary and Electric Lighting Committees of Leeds it was determined to support the Government Bill, and he moved a resolution to that effect, and the meeting determined that a clause should be added to the resolution asking the Government to make the consent of a corporation a condition precedent to a provisional order being granted to a company. The resolution was seconded by the Town Clerk of Birmingham (Mr. E. Orford Smith), and supported by several representatives of large bodies. Sir George Morrison said during the discussion that had taken place an attempt had been made to saddle the failure of the electric lighting companies upon the purchase clause of the Electric Lighting Act of 1882. Several gentlemen of engineering eminence had told him that the real cause of the failure, apart from the reckless speculation which had taken place in electric lighting shares, had been the fact that electrical science itself had not yet succeeded in being able economically to supply large towns from a central power station. The borough engineer of Leeds and himself had discussed the matter, and he thought it was not impossible that other modes of power (the essential factor in all electric lighting installations) which would facilitate the use of the electric light in large towns would be available, and practically render the functions of electric-light companies worthless. The resolution was carried unanimously, and on the motion of the Mayor of Huddersfield, seconded by the Town Clerk of Longton, it was unanimously resolved that, "The town clerks of Leeds, Nottingham, and Birmingham, and representatives from the Corporations of Liverpool, Manchester, Blackburn, and Sheffield, be requested to give evidence in support of the resolution of the Association before the Lords Committee on Electric Light Bills, which sits for the first time to-day."

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS, FRIDAY, MARCH 26.

ELECTRIC LIGHTING ACT (1882) AMENDMENT (NO. 1) BILL.

Lord Rayleigh, in moving the second reading of this Bill [*Electrician*, 12th March], reviewed the history of electric lighting down to the passing of Mr. Chamberlain's Act of 1882, which, instead of promoting or regulating the system, had really put an end to it so far as the lighting of of towns and houses on a permanent footing was concerned. The ground of complaint against that Act was in the 27th Clause, by which local authorities had the option of compulsorily purchasing electric lighting undertakings after 21 years, and paying for the undertaking, plant, &c., only the value at the time of purchase—*i.e.*, when the machinery might be much worn or even obsolete. If the terms of purchase had been reasonable the mere shortness of time might not have constituted an obstacle in the working of the clause; but no capitalist would care to invest his money in electrical enterprises on such terms as the Act imposed. It seemed to him that there was too much jealousy at the present day of a private company making large profits. Most undertakings were more or less of a speculative character, and if some were great successes others were miserable failures, so that one ought to be balanced against the other. He admitted that in the evidence given before the Select Committee of the House of Commons some of the expert witnesses seemed to think that 21 years might suffice as a minimum; but not in conjunction with such terms of purchase at the end of the period as were embodied in the Act. To obtain some relaxation in its provisions, it was thought at first that a prolongation of the period, coupled with fairer terms of purchase, might meet the case; and this was the principle on which the second Bill (Lord Bury's No. 2 Bill) was framed. If the question were merely one of raising a large amount of capital in order to make a start once for all, such a relaxation would meet the case. But enterprise like that of electric lighting was largely experimental, and would continue to be so for many years. Large amounts of capital would not be invested in it, except slowly and gradually: and this would involve going into the

Digitized by Google

market from time to time to obtain fresh capital. In what position would the company be to effect this object? After a considerable fraction of its time had expired it would be impossible to attract fresh capital to their enterprise. The public would not be well served during the waning years of the term, and no areas would be extended or improvements introduced. He considered that the best course was to place electric light and gas on the same footing as regards both privileges and obligations. In conclusion, he particularly deprecated any further delay in giving a fair chance to this most interesting application of modern discovery and invention for the relief of the gloom and unhealthiness of our large cities.

The Bill was read a second time.

No. 2 BILL.

Viscount BURY then moved the second reading of his Bill (the text of which we print below), which fixed the term at 42 or 63 years, at the end of which period the local authority would have to pay the price of a going concern. The Act of 1882 had made electric lighting an impossibility by frightening away investors and capitalists, who naturally declined to risk their money in a concern which might be bought compulsorily for the price of old iron at the end of 21 years.

This Bill also was read a second time.

Viscount BURY then moved that these two Bills should be referred to a select committee.

Lord HOUGHTON, on the part of the Government, admitted that some of the stringent provisions of the Act of 1882 must be relaxed. But sufficient security would have to be taken against the creation of new and perpetual monopolies. He objected to Lord Rayleigh's Bill because it would establish a new series of vested interests, and the Bill of Viscount Bury would create a more dangerous because more insidious form of monopoly. Her Majesty's Government were prepared to extend the minimum period from 21 to 30 years, and with the consent of the local authority to 42 years from the date of the concession. He suggested that these two Bills, together with the Government Bill, should be referred to a committee of the whole House rather than to a select committee.

Viscount BURY declined to adopt this course, and the discussion was adjourned until the Government Bill should be before the House.

THURSDAY, APRIL 1.

No. 3 BILL.

Lord HOUGHTON moved the second reading of this Bill, consisting of one clause extending the term of the provisional order from the Board of Trade to 30 years, and, provided the consent of the local authority was obtained, to a further period of 12 years, or with the permission of the Board of Trade for 10 years. Then, at the end of every 10 years the purchasing powers of the local authority might be exercised.

The Bill was read a second time.

Nos. 1, 2 and 3 BILLS.

Viscount BURY moved that these three Bills be referred to a select committee.

Lord HOUGHTON opposed the motion on the ground that all the technical and commercial evidence on the subject had been obtained on the Bill of 1882, and that a fresh select committee would prevent any legislation before the end of next session.

After some discussion, in which Lords GRIMTHORPE, HOUGHTON, BRAMWELL, RAYLEIGH, and Earl CAMPERDOWN took part, Earl Granville consented to the reference to a select committee, expressing a hope that it would arrive at a conclusion as soon as possible.

Electric Lighting Act (1882) Amendment (No. 2).

(Introduced by Viscount Bury.)

HOUSE OF LORDS.

An Act to Amend the Electric Lighting Act, 1882.

Whereas it is expedient to amend the Electric Lighting Act, 1882:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited for all purposes as the Electric Lighting Act, 1886, and this Act and the Electric Lighting Act, 1882, may be cited together as the Electric Lighting Acts, 1882 and 1886.

2. The Electric Lighting Act, 1882, is hereinafter referred to as "the principal Act," and this Act, so far as is consistent with the tenour thereof, shall be construed as one with the principal Act.

In this Act the several words and expressions to which meanings are assigned by the principal Act have the same respective meanings, unless there be something in the subject or context repugnant to such construction.

3. Section three (sub-section one) of the principal Act (1882) shall be read and have effect as if the following words, "Provided always, that where such local authority is already the holder of a license or provisional order for the supply of electricity within the area or any part of the area in respect of which the application for a license is made, the Board of Trade may, if it shall think proper, grant the license for which application is made, without the consent of the local authority," had been inserted at the end of that sub-section.

4. Section twelve (sub-section two) of the principal Act shall be read and have effect as if the following words, that is to say, "except so much thereof as relates to the use of any burner other than those such as have been provided or approved of by the undertakers," had not been inserted in that sub-section.

5. Section eighteen of the principal Act shall be read and construed as if the words "In cases in which the supply of electricity is measured by and charged for according to meter" had been inserted at the commencement of the section.

6. Section 27 of the principal Act is hereby repealed, and in lieu thereof the following provisions shall have effect; that is to say, "Where any undertakers are authorised by a provisional order or special Act to supply electricity within any area, any local authority within whose jurisdiction such area or any part thereof is situated may, within six months after the expiration of a period of forty-one years from the date of the passing of the Act confirming such provisional order, or of such special Act, and within six months after the expiration of every subsequent period of seven years, by notice in writing require such undertakers to sell, and thereupon such undertakers shall sell to them their undertaking, or so much of the same as is within such jurisdiction, upon terms of paying the then value thereof as a going concern. Such value in case of difference shall be determined by arbitration, and due regard shall be had to the nature and then condition of the buildings, works, materials, and plant of the undertakers, and to the state of repair thereof, and the suitability of the same to the purposes of the undertaking, and where a part only of the undertaking is purchased, to any loss occasioned by severance. The Board of Trade may determine any other questions which may arise in relation to such purchase and may fix the date from which such purchase is to take effect, and from and after the date so fixed, or such other date as may be agreed upon between the parties, all lands, buildings, works, materials, and plant so purchased as aforesaid shall vest in the local authority which has made the purchase, freed from any debts, mortgages, or similar obligations of such undertakers, or attaching to the undertaking, and the powers of such undertakers in relation to the supply of electricity under this Act or such provisional order or special Act as aforesaid, within such area or part thereof as aforesaid, shall absolutely cease and determine, and shall vest in the local authority aforesaid."

Building Trades Exhibition.—At the Architectural and Building Trades Exhibition, now being held at the Agricultural Hall, Islington, Messrs. Cordner, Allen, and Co. exhibit specimens of the "Byng" patent acoustic telephone and "Leo" patent line guide and insulators. The telephone is simple, and will be found useful for business premises and country mansions. They also exhibit a variety of electric bells and other instruments. Messrs. Coe and Smith send a large selection of electric bells, indicators, speaking tubes, &c., including Smith's patent pull and push for electric bells, which dispenses with the use of the spring crank hitherto used. Messrs. Eck, Callow, and Co., of Clerkenwell-green, have also an excellent display of electrical bells, testers, fire alarms, and general electrical instruments. Messrs. E. Jacobs and Co. show a "Radcliffe" silent gas engine (Wordsworth and Wolstenholme's patents). A 2 horse-power engine is shown, for which many advantages are claimed, not the least of which is that it is no infringement on previous patents.

LEGAL.

A Director's Fees.

In the Queen's Bench Division of the High Court of Justice, on Saturday, before Mr. Justice Grantham, the case of Gilman *v.* the Gülcher Electric Light and Power Company (Limited) was tried. The plaintiff, who was represented by Mr. Candy, claimed to be entitled to £220 for his attendances as director of the company. The Articles of Association provided that £1,500 should be set apart by the company for the directors, who distributed it among themselves at the rate of £250 for each director, and £500 for the chairman. But the other directors refused to sit with Mr. Gilman, and, consequently, although he presented himself, he did not attend any meeting in May, 1885, and resigned on May 28th of that year. The directors passed a resolution declaring the plaintiff not entitled to any fees for 1885; but they admitted that he was entitled to payment up to the end of 1884. The company, represented by Mr. Pyke, set up a counter claim for £100 due from the plaintiff as calls upon shares held by him in the company. There were also standing in the name of Mrs. Gilman 120 shares, upon which the plaintiff had paid some of the calls.

The judge decided that the defendants were not entitled to recover from the plaintiff the outstanding calls upon the shares registered in his wife's name; but upon striking a balance between the £70 due for fees in 1884 and the £100 due from the plaintiff upon his own shares, he found that £29 odd was due to the defendants, and he gave judgment for that sum with costs.

COMPANIES' MEETINGS & REPORTS.

Montevidean and Brazilian Telegraph Company.

The following is from the report of the Directors, which was submitted at the ordinary general meeting of the Company on the 7th inst. We are unable to add any other information, reporters not being admitted to the meeting:—The Directors regret that the percentage of gross revenue receivable from the Western and Brazilian Company again shows a serious falling off, being £1,529. 12s. 5d., as compared with £1,860 in 1884. The reduction in receipts, as the shareholders are aware, began in 1883, in which year the severe competition of the Brazilian Government land lines compelled a heavy reduction in the rates previously charged. The continued and increased reduction is attributable mainly to the great depression in business affairs which has prevailed during the year, and prejudicially affected

Digitized by Google

the receipts of the Western and Brazilian Company in common with those of telegraph companies generally. At the same time the income of the Western and Brazilian Company has been specially affected by the exceptionally low rate of exchange which has existed, the average rate for 1885 being about 18¾d. per milrei as compared with about 21¼d. in 1884. The balance to the credit of revenue account amounts to £494. 4s. 9d., which will be absorbed in making provision for the redemption of debentures. The Directors regret that they have been unable to make further progress with the negotiations for the disposal of the undertaking to the Western and Brazilian Telegraph Company.

Eastern Extension, Australasia, and China Telegraph Company.

Report and accounts of the Directors for the half-year ended 31st December, to be submitted to the twenty-fifth ordinary general meeting, to be held at the Cannon-street Hotel, on the 14th inst., at 2 o'clock.

The gross receipts, inclusive of Government subsidies, have amounted during that period to £247,017. 6s. 4d., against £248,087. 19s. 5d., for the corresponding half year of 1884. The working and other expenses, including £27,236. 16s. 1d. for cost of repairs to cables and expenses of ships, absorb £71,473. 6s. 9d. against £79,496. 9s. 1d. for the corresponding period of 1884, leaving a balance of £175,543. 19s. 7d. From this is deducted £3,763. 2s. for income-tax, and £41,595 for interest on debentures and contributions to sinking funds, leaving £130,185. 17s. 7d. as the net profit for the half year, which, with £32,858. 6s. 11d. brought forward from the previous half year, leaves a balance of £163,044. 4d. 6d. Against this the balance of cost of the Singapore-Saigon and Penang-Rangoon cable renewals, the cost of duplicating the Victoria-Tasmania cable, and the cost of connecting and establishing a cable station at the North Saddles (China), amounting altogether to £36,076. 2s. 1d., have been charged. One quarterly interim dividend of 1¼ per cent., amounting to £31,250, has been paid for the half year, and it is now proposed to distribute another of like amount, together with a bonus of 2s. per share payable on the 15th instant, making with the interim dividends and bonus paid for the first half year a total distribution of 7 per cent. for the year 1885. The balance of £39,468. 2s. 5d. has been carried to the general reserve fund, which now stands at £565,644. 6s. 1d. In pursuance of the conditions upon which the issue was made, 102 of the Company's 5 per cent. debentures of 1880 were drawn by lot on the 15th ultimo for payment at par on the 1st May next. The new cable steamer, "Recorder," referred to in the last report, has arrived at her station at Singapore, and the ss. "Agnes" has left for England to be overhauled for requisite repairs. The cost of the "Recorder," amounting with cable machinery and electrical apparatus to £42,606. 14s. 2d., has been deducted, as shown in the balance-sheet, from the Maintenance Ships' Reserve Fund. The cable between Victoria and Tasmania has been duplicated during the half year under review out of the Company's stock of spare cable at Singapore, and the cost (£31,190. 5s.) has been charged, as above stated, against revenue. The principal cable repairs during the half year have been on the Java-Australian and Penang-Singapore sections, but the communication has been uninterruptedly maintained by means of the duplicate lines. All the Company's cables are now in good working order. In consequence of the frequent interruptions of late years to the Penang-Singapore (original) cable resulting in a large annual expenditure for repairs, your Directors have determined to replace it with a new cable of brass-ribboned type, and a contract has been entered into with the Telegraph Construction and Maintenance Company for carrying out the work. It is anticipated that a large proportion of the old line will be picked up, and after it has been overhauled and re-served will be available for extensions or renewals in other directions. Your Directors regret to report that their efforts to induce the Indian Government to lower the transit rate for international messages across India have been unsuccessful. As, however, the Australian Colonies were, at Berlin, led to expect some reduction in the cable charges, the company, after consultation with the Agents-General, and notwithstanding the refusal of the Indian Government to participate in the reduction, have decided to reduce the tariff from the 1st July next by 1s. 4d. per word unconditionally, and to make a further substantial reduction provided the colonies agree to certain conditions proposed by the Company. It has also been decided to reduce the tariff between Europe and China from 8s. 4d. to 7s. 1d. per word, to take effect from the same date. The South Australian Government land line between Port Darwin and Adelaide has, as usual, been well maintained during the past half-year. In accordance with the Articles of Association, the Right Honourable Viscount Monck and Sir William McArthur, K.C.M.G., retire by rotation, and offer themselves for re-election. The retiring auditors, Mr. Henry Dever and Messrs. Quilter, Ball and Co., also offer themselves for re-election.

Indo-European Telegraph Company.

Directors' report for 1885, to be presented at the nineteenth ordinary general meeting of shareholders, to be held at the Cannon-street Hotel, on the 21st inst., at 12 o'clock:—

The Company's revenue from all sources for 1885 amounted to £116,150. 3s. 1d. as compared with £98,103. 11s. 9d., showing an increase of £18,046. 11s. 4d., or rather more than 18 per cent. The expenses were: On commercial and general account, £25,509; on maintenance account, £25,088. 8s. 11d., including £145. 5s 11d. paid to the Russian Government. Total, £51,597. 8s. 11d., as against £53,323. 19s. 6d., a decrease of £1,726. 10s. 7d. This is owing to the exceptional outlay on the duplicate Kertch cable which appeared in last year's accounts. The maintenance expenditure, however, includes the cost of alterations and improvements in the Company's lines. On commercial account there is an increase of £1,637. 7s. 7d., mainly occasioned by staff for additional through circuits and the expenses attendant upon the increased business done. Deducting the above expenses, taking credit for £4,578. 11s. 7d. balance brought over from 1884, and debiting income tax, there remains the sum of £67,456. 5s. 1d. From this amount £10,625 has already been paid for interim dividend, leaving a balance of £56,831. 5s. 1d. The Directors, after setting aside £15,000 to the reserve fund, propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 30s. per share, both free of income-tax, making in all 12 per cent. for the year, and carrying forward £1,456. 5s. 1d. to the credit of 1886. The extra cable circuit secured by the new agreement with the Post Office, and the other additions made out of revenue to the Company's system, aided by the second wire granted by the German Government, by which two special circuits are secured from London to Teheran, continue to prove of great advantage to the working of the Company's system. The above improvements have also contributed to enable the Company to deal satisfactorily with the additional business thrown upon the lines during the past year. The large augmentation of revenue is quite exceptional, and is owing to the total interruption of the Eastern Company's lines for some three weeks, the disturbances in Burmah and the Afghan frontier question, and it is satisfactory that the £18,046. 11s. 4d. of additional revenue has only occasioned an increased expenditure on commercial account of £1,637. 7s. 7d. At the Telegraph Conference of Berlin, in response to the desires expressed by the Indian Government and the German Postmaster-General, His Excellency, Dr. von Stephan, it was determined to reduce the rate to India from the 1st of July next from 4s. 7d. to 4s. per word. This will cause a diminution of the Company's revenue, but the Board were of opinion that the time had come for a material reduction in the tariff. Reductions were also arranged for, to Australia and China, the amounts of which are not yet fixed, to take effect from the same date. The following Directors retire by rotation, and offer themselves for re-election:—Col. James Holland and H. H. Meier, Esq. The auditors, Messrs. C. F. Kemp, Ford, and Co., public accountants, retire and offer themselves for re-election.

NOTES.

AUSTRIA.—Experiments are to be carried out to connect Vienna and Pesth telephonically.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 9th inst. amounted to £2,862.

ESTIENNE'S TELEGRAPH.—It is stated that some satisfactory experiments have been made direct between Paris and Berlin with M. Estienne's apparatus.

TONKIN.—It is said that the first occupation of M. Paul Berl upon his arrival at Tonkin was to endeavour to develop and systematise telegraphic and telephonic communications.

WEST INDIES.—The cable between St. Vincent and St. Lucia, which we announced in our last week's issue as being interrupted, has been promptly repaired. That between Dominica and Guadeloupe, however, remains interrupted.

ROYAL INSTITUTION OF GREAT BRITAIN.—According to the arrangements for the Friday evening meetings after Easter, on Friday, May 28th, Prof. Oliver Lodge, D.Sc., will lecture on "Electrical Deposition of Dust and Smoke."

THE MINES COMMISSION.—After seven years' labour the final report of this commission has been issued. The value of electricity as an illuminant for mining purposes is briefly touched upon, and is considered in our leader in this issue.

AMERICA.—New York has 23,038 gas lamps, and 647 electric lights. Boston has 9,781 gas lamps, and 401 electric lights. Baltimore has 5,191 gas lamps, and 243 electric lights. These figures are given under the authority of the *Scientific American*.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 9th inst. were £2,369, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

FIREPROOF CABLE.—At the recent fire at the Liverpool Telephonic Exchange, we understand that two 100-wire fireproof cables, recently supplied by Messrs. Walter T. Glover and Co., Manchester, were exposed to the full fury of the flames, and stood the test thoroughly.

INSTITUTE OF CIVIL ENGINEERS.—On the 31st ult. there were on the books of the institution 20 honorary members, 1,542 members, 2,111 associate members, 501 associates, and 926 students—together 5,100, being a net effective increase of 313 during the preceding twelve months.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—At the meeting of the Board of Directors on April 14 Mr. Alfred Marshall, formerly partner in the firm of Messrs. F. Huth, Grüning and Co., of Valparaiso and Lima, was unanimously elected chairman of this company, in place of the late Mr. Robinson Kendal.

CARDIFF.—Forty arc lights, each of 2,000 candle-power, are shortly to be put up at the Barry Docks, Cardiff, so that the work of excavation and construction will be able to be continued day and night. Mr. Walker, the contractor, is fully convinced that he can by this means complete the dock by September, 1888.

THE EFFECT OF A SILENT DISCHARGE ON A SENSITISED PHOTOGRAPHIC PLATE.—Dr. Tommasi has recently brought before the French Academy of Science an account of experiments made to show that the silent discharge from an induction machine has upon a sensitised photographic plate the same effect as the ultra violet or chemical rays. The experiment must be performed in complete darkness.

NATIONAL SOCIETY OF INDUSTRIAL SCIENCES AND ARTS.—*L'Electricien* of April 10th says: We have just received the general programme of the first International Exhibition of this society, which will take place at the Palace of Industry from July to November. An entire group, the tenth, is devoted to electrical industries. For all information apply to the Management of the Society, 24, Rue Saint Marc, Paris.

EXHIBITION IN NEWCASTLE.—It has been definitely arranged to hold in Newcastle an International and Colonial Mining, Engineering, and Industrial Exhibition in 1887, in celebration of the Royal Jubilee. The exhibition, which is to be held in the grounds of Singleton House, Northumberland-street, will be divided into fourteen departments with subdivisions, thus guaranteeing a larger display of products.

CHEAPER TELEPHONY.—We notice that the Lancashire and Cheshire Telephonic Company are instituting a cheaper service. They are developing what may be termed a multiplex service, in which several subscribers use the same wire. The rates for this new service are, when used for commercial purposes, £15 per annum, reduced to £12 if a three years' contract is given. When used for domestic purposes, £10 per annum, or £8 per annum for three years' contract.

CLUBDOM.—The Junior Carlton Club has arranged to duplicate the electric light machinery, and to introduce a set of accumulators of a thousand ampere-hours' capacity. The extension of the lighting—as was the case with the original lighting—is in the hands of Messrs. B. Verity and Sons, who are also going to put 100 lights in the grand circle of the Alhambra Theatre, and are now about commencing work at Scarborough, where the installation will consist of 120 lights.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—In pursuance of the conditions upon which the Five per Cent. Australian Government Subsidy Debentures were made, 251 debentures of £100 each were drawn by lot on the 12th April, at the offices of the company. The said debentures will be paid off at par on the 1st day of July next, at Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C., after which date interest on them will cease. Full particulars will be found in our advertising columns.

WHAT IS A ROADWAY?—A new political periodical, *The State*, hazards the following bit of applied science in its first number. The italics are ours. "Electricity for driving tramcars and even underground railway trains at much less than the cost of horse, or steam, or air, or cable power—that is the latest thing we hear of in the way of science. The public will soon hear of the scheme in detail. The only novelty in it is that *no special roadway will be required, for electric cars are already running along the beach at Brighton and elsewhere.*"

BALLOONING.—Mr. Eric S. Bruce has been engaged lately in arranging a captive balloon for exhibition during the summer season at the Crystal Palace. The balloon will have a capacity of 80,000 cubic feet, and will carry several passengers at a time. It is proposed to have an ascent by day and night. At night time the electric light will be used by means of the apparatus devised by Mr. Bruce, and his system of flashing signals will be demonstrated. Several important improvements in the details of the signalling apparatus have been effected, the result of the experience obtained during the experiments carried out for the Government.

TELEPHONE CHARGES.—Mr. C. Lever, writing from Bowden to the *Manchester Guardian*, criticises somewhat severely the high charges made by the Lancashire and Cheshire Telephonic

Digitized by Google

Exchange Company. It will be seen from another note that the company is taking some action in the matter. Mr. Lever's criticism, however, is more one of detail for the shareholders of the company to consider, as well as the subscribers, rather than a scientific one. He maintains that the company pays the parent company £2 per annum for each pair of instruments, which is an unnecessary payment and should be stopped, and the subscriptions decreased in proportion.

TELEPHONY IN FRANCE.—No one has a right in France to establish a telephone line intended for private use without having first obtained authorisation from the State, and by paying an annual tax. It is felt that while this is just, so far as the public lines are concerned, it falls very heavily upon men who connect their house with their factory or their sale room, as in that case the State is not prejudiced, nor is there any diminution of revenue. A petition has been sent to the Minister of Posts and Telegraphs on this subject, and a request made that he may find it possible to moderate, even if h does not abolish entirely, the tax hitherto imposed by the State.

ABERDEEN AND THE TELEPHONE.—The New Works Committee of the Harbour Board of the "granite" city have recently been considering the expediency of erecting telephone poles on the quays and reclaimed land. As the result of their deliberations, they have resolved to recommend to the Board that the Telephone Company should remove the poles at present placed along the quays on the south side of the docks; that in the event of the companies being unable to carry the wires over the private property along this route they should be allowed to place the poles along Commercial-road, and, among other conditions, that the company should be required to relieve the Board of all responsibility in connection with the erection of poles and wires.

ELECTRICITY IN THE KITCHEN.—Miss Harriet Lawrie, otherwise known as the "Electric Star," describes in a letter to the *Era* how she was able to light her kitchen fire from her bed room through the medium of electricity. Having made the necessary connections between the fireplace and her room, she says:—"In my bed room I placed a four-cell bichromate battery, with a lever attachment, to raise the elements from their cells. In order to light my fire I had only to raise the lever (which was placed within my reach), thus lowering the elements, completing the circuit. The platinum wire in the kitchen then became incandescent, setting fire to the lightning paper, which in turn set fire to the tissue, and this to the patent wood, &c., and it was a complete success."

THE SILVERTOWN COMPANY.—Several changes in this Company's Board of Directors took place at the last extraordinary general meeting through the death of the late chairman, Mr. Henderson. Mr. Robert Henderson, nephew of the late chairman, and son of the late Mr. Robert Henderson, who with Mr. S. W. Silver, was one of the founders of the Silvertown Company, has been appointed to a seat on the Board. This gentleman's position in the City of London makes him a valuable addition to the direction of the company. Mr. S. W. Silver has become chairman of the company, and Mr. Mathew Gray, the general manager, has joined the Board as Managing Director. The trusteeship for the debenture holders has devolved upon Mr. George Henderson, son of the late chairman.

GALVANOMETERS.—M. d'Arsonval presented to the French Physical Society, at the meeting of March 19th, a galvanometer with a movable circuit of great sensitiveness, which he has arranged for his physiological researches. The frame carrying the coil of the galvanometer is suspended in a field given by two parallel hard iron magnets, whose like poles are in the same direction. The lines of force are drawn in by a piece of soft iron placed at the centre of the four poles and of the suspended frame of the galvanometer. The inventor says the deviations are rigorously proportional to the intensity of the current in the coil. The intensity of the magnetic field may be varied by placing the two magnets farther apart or closer together. This galvanometer has the same dead-beat property as the inventor's former model.

PETROLEUM AS FUEL.—We have great pleasure in announcing that Messrs. Ransomes, Sims, and Jefferies, of Ipswich, supply their portable steam engines with an ingenious and simple apparatus which enables them to burn petroleum, and some of the engines so fitted have already been at work for a considerable time, burning only petroleum, with satisfactory results. Petroleum, as is well known, is procured in some countries, such as Russia, Brazil, &c., from natural springs or wells, and it is consequently obtainable there in its crude state at a very much lower cost than coal; it is therefore of the utmost importance that engines sent into these countries should be able to burn every description of fuel that may be indigenous, thereby utilising steam at its minimum cost. It is suggested that these engines will be largely used for electric light purposes in countries where petroleum is cheap and coal dear.

A MAGNETISED CORSET.—That ladies may have trouble with their watches, even if they take care not to bring them near a dynamo, is shown by the following story told by the *Electrical World*:—A young woman of Columbus, Ga., about to visit the station of the electric light company, was told to leave her watch at home lest it be magnetised by the strong electric current. She did so, but complained afterwards that her watch would not keep good time. She sent it to a jeweller, but he reported that it was not magnetised, and kept good time. Still, whenever she carried it, her time was too slow, although when she left it in her room it ran correctly. A gentleman who knew of the circumstance suggested to the young lady that she wear another pair of corsets when next she carried the watch. She did so, and had no further trouble with the watch. The steel springs in her corsets had been magnetised.

PROTECTING BUSINESS PREMISES.—We are glad to see that the American plan of utilising electricity for protective purposes—at any rate against burglars—is becoming more common. Not twelve months since the premises of Mr. Horton, in Sheffield, were broken into, and £100 worth of ivory stolen. After that robbery permission was obtained for an electric bell to be attached from the warehouse to the house of Mr. Whittaker, who resides on the adjoining premises. The electric bell was placed in one of Mr. Whittaker's bed rooms, and a few days ago the warehouse was again broken into just before 10 o'clock. Mr. Whittaker was quietly reading, when he suddenly heard the electric bell ringing in the bed room. Of course he knew that something unusual had occurred, and after giving a hasty glance round his own premises, to see that they were secure, he made with all speed to the Central Fire Station. He obtained the assistance of the police, and the burglars were captured.

COLONIAL AND INDIAN EXHIBITION.—A meeting of the reception committee was held on Monday at the Society of Arts. The committee considered a report from the sub-committee as to the arrangements which could be made for excursions for colonial and Indian visitors. Mr. Somers Vine, the official agent of the Exhibition, attended, and reported to

Digitized by Google

the committee the arrangements which had been made with the railway companies with the view of affording extended facilities for railway travelling to all colonial and Indian visitors coming to the Exhibition. The chairman reported that in accordance with the wishes of the committee, and with the approval of H.R.H. the Prince of Wales, he had communicated with the mayors of some of the chief provincial cities asking if they would arrange for visits of parties of distinguished visitors. It was resolved that a subscription list should be opened; and the hope was expressed that those who have enjoyed the benefit of colonial hospitality will avail themselves of this opportunity of contributing to the entertainment of those who come to England from the colonies and from India for the purpose of visiting the Exhibition.

The Blackening of Incandescent Lamps.—Mr. Lucas, in a communication to the Academy of Sciences, suggests that some absorbent be introduced into the lamps to stop the dulness that gradually arises in them. He says:—"We know that in incandescent lamps there is produced in course of time a carbonaceous deposit upon the inner surface of the glass globe. This gradual decrease of transparence would be especially injurious for powerful incandescent foci. I have endeavoured to determine the true cause, and my experiments prove that it consists in the presence of molecules of oxygen within the lamp. We find, in fact, that the rate of increase of the deposit is in direct relation with the pressure of the internal gas We should arrive at an infinite slowness, or, in other words, at the cessation of the deposit, if we could obtain and preserve an absolute vacuum within the glass globe. A molecule of oxygen, not removed, combines with the carbon near its junction with the metallic conductor, a region in which the temperature cannot reach the melting point of the conductor. There is thus formed a molecule of carbonic oxide. This molecule, then, coming in contact with the incandescent portion, the temperature of which is high enough to produce dissociation, projects the carbon against the inner surface of the glass globe and leaves the oxygen at liberty to combine again."

Messrs. R. E. Crompton and Co.'s Works.—The students of the Institution of Civil Engineers, accompanied by Mr. Forest, the well-known secretary, visited Messrs. Crompton's electric light works at Chelmsford on Wednesday, the 7th inst. On their arrival at 1 p.m., after light refreshment, they commenced their inspection of the works in the heavy machinery department; here they had opportunities of examining the various parts of dynamos of all sizes, and also of armatures in all stages of construction. In this department, among the various large tools which were objects of considerable attention, was a circular saw used in cutting up 8in. square bars of cold wrought iron; a large new milling machine manufactured by Messrs. Kendall and Gent; also a large planing machine used for all heavy dynamo bed plates. The visitors next passed into the testing department, which was found to be well fitted with all the most modern appliances, including very large rheostats, a large number of measuring instruments, photometers, &c. Passing onwards, attention was drawn to a three-cylinder compound Willans engine, driving direct a large Crompton dynamo. This set was of the type exhibited at the International Inventions Exhibition, and was here used for doing all electrical work required in the works for shop lighting, both arc and incandescent lamps, and also for driving motors, working the fans in the smith's shop, and all the shafting in the pattern shop. Ascending to the first floor, or bobbin shop, the visitors were enabled to examine armatures of every size and description in various stages of completion, the sizes of these varying from an armature able to work 12 lamps at 2,000 revolutions to one capable of generating 100,000 watts at 400 revolutions. On this floor also projectors of all sizes, and hand lamps of English and other patterns were on show. The new pattern of high pressure steam valve, which the firm had just completed, was very favourably remarked upon. Proceeding to the next floor, instruments, switches, and minor fittings of every sort and description were to be seen in progress. Returning to the ground floor the visitors were shown through the erecting shop and stores, and thence to the pattern shop, foundries, painting, and smith's shops. In this latter a high-pressure steam hammer was seen, used for forging, shearing, and punching. In the new erecting shop was seen three complete combined plants each capable of giving 100,000 watts at about 400 revolutions, one of these being specially put under steam for the inspection of the visitors. Prominent among other features of interest which cannot be detailed at length were the fittings for a complete set of gear necessary for a light ship. These embraced dynamos, engines, boilers, glazed lantern, containing four arc lamps suspended on gimbals, &c. The whole works, which employ upwards of 400 men, show in every department the steady progress which this branch of engineering is now making.

Electric Light in Mills.—The Gülcher Electric Light and Power Company have recently erected for Messrs. Jonas Brook and Brothers, Meltham Mills, Yorkshire, one of the largest installations of incandescent lamps carried out in that county. The following is the arrangement of the lamps:—No. 1 large room, comprising black dressing, winding, and beaming department, 140 lamps, 20 c.-p.; No. 2 large room, comprising white dressing and beaming machines, 71 lamps, 20 c.-p.; dressing room, comprising colour dressing machines, 36 lamps, 20 c.-p.; starch boiling room, 4 lamps, 20 c.-p.; black stock room, 3 lamps, 20 c.-p.; slaying room, 4 lamps, 20 c.-p.; engineer's room, 1 lamp, 20 c.-p.; stoves, 1 lamp, 20 c.-p.; total number of lamps, 260. The 260 lamps in this installation are of Swan-Edison 90-volt type, and are driven from a No. 5 Gülcher compound-wound dynamo machine of their latest and most improved type. The machine is capable of giving a current of 220 amperes at 100 volts E.M.F., or an electrical output of 22,000 watts, at a speed of 500 revolutions per minute, so that it is large enough to enable the installation to be extended should Messrs. Brooks and Brothers desire additional light. The motive power for driving the dynamo is taken from the main shaft, which is fitted with a friction pulley. This avoids the inconvenience of fast and loose pulleys and striking gear, and answers the purpose admirably. The current from the dynamo is led by cables neatly cased into three main switches and cut-outs, each fitted in a box with lock and key. The current is then split into three circuits, one of 140, one of 84, and one of 36 lamps, and led to the different departments. The lamps are tapped off the mains in circuits of five. Each lamp is fitted with a switch and cut-out, enabling any portion of the installation to be switched on or off as occasion offers. The incandescent lamps themselves are all suspended from the ceiling by means of long wrought-iron pendants, and in order to obtain the utmost effect from the lamps, each is fitted with an opal reflector 6in. in diameter. This installation is the third of the Gülcher Company that Messrs. Brooks have adopted. The second installation has been supplied for lighting their Royd Edge Mill, where a No. 4 compound-wound dynamo is used to run six arc lamps in the dye-houses, and twenty incandescent lamps in the different departments. As this installation will ultimately be extended, the dynamo machine is capable of

Digitized by Google

running 60 more incandescent lamps of 20 candle-power.' This installation shows the advantage of a system of electric lighting for factory work, which enables arc lamps to be used in dye-houses or large buildings, and incandescent lamps in the small rooms or departments, both being driven from one dynamo machine, and in fact from the same arrangement of circuits. The system has been adopted in other mills in Yorkshire, and the following may be mentioned as the most prominent firms who are using it:—Messrs. Jas. Watkinson and Sons, Holmfirth; J. Sykes and Co., Brockholes; and E. Fox and Son, Dewsbury.

Adoption of the Electric Light in Government Offices.—The factory of the Royal Army Clothing Depôt, Pimlico, has been fitted with a large electric light installation. This branch of that establishment consists of a large hall, 200 by 38 by 48ft., with side galleries three stories in height, besides two large ironing and pressing sheds, engine and boiler rooms, fitters' shops, machine and general store rooms, and clerks' offices. The hall is fitted up with sewing machines, driven by shafting from a steam engine, and sewing tables. The side galleries are occupied by cutters, viewers and inspectors of work completed, trimmers, finishers, &c. The total number of workpeople engaged in the hall alone is 1,600. The entire establishment was until lately lighted by gas, the total number of burners being 850, each consuming from six to eight feet of gas per hour, making the air very vitiated. The light was unsteady, and owing to the necessity of keeping it close to the workers, very injurious to their eyesight and general health. It was therefore proposed to substitute the electric light. In 1884 some interesting experiments were made to determine the best positions for the lamps and the candle-power that should be adopted. A small Schukert dynamo was hired, and 66 lamps of 10, 16, and 20 candle-power by Messrs. Woodhouse and Rawson, Swan, Edison, and Pilsen-Joel were fitted on standards at sewing machines and tables. By the use of counter shafting the engine-power of the factory engines was utilised. These experiments proved that 10 candle power lamps were most suitable. The installation was then proceeded with from designs of the R.E. Department of the Home District. The dynamo and switch-board were obtained by tender from the Anglo-American Brush Company, the former being one of their Victoria compound-wound slow speed type, giving 110 volts at the terminals. The engine is one of Messrs. Hornsby and Son's semi-fixed compound engine and boiler, of 25 nominal horse-power, with their new patent governor. No counter-shafting is used, the power being transmitted direct from the engine fly-wheel to the dynamo by one of Messrs. Cayley's 12in. leather belts, and the running is remarkable for its steadiness. The lamps are 10 candle-power, 52-volt Victoria, supplied by the Anglo-American Brush Company, arranged in parallel circuits, two in series. Owing to the probability of extensions, considerable margin has been allowed in the size of the cables, which were supplied by Messrs. Callender and Co. and W. T. Glover and Co. The lamp leads were supplied by Messrs. W. T. Glover and Co. and Latimer Clark and Co. The whole of the wiring, &c., was very well carried out by workmen hired from the Gülcher Electric Light Company, under the superintendence of Mr. E. Dawson, A.S.T.E., assistant surveyor. This company also provided all the standards, cut-outs, cable junctions, and fuses, and general small fittings. Total number of lamps, 1,070; total prime cost of the installation to the War Department, £2,100, including engine and fitting up engine room. Following that at the Tower of London, carried out in 1884, this is the second electric light installation made by that department.

The Electric Lighting Act Amendment Bills.—Mr. W. Livesey writes in the *Journal of Gas Lighting* with regard to the amendment in the Bills now before the House of Lords, that nearly all these provisions (amendments) are taken from the Gasworks Clauses Act, or special Acts relating to gas, and, so far as circumstances permit, are word for word the same. There is nothing in these provisions prejudicial to gas companies, or that would entitle the companies to be heard against them; notwithstanding, the Gas Companies' Association have given instructions for the proceedings to be watched, and permission to be heard applied for if it should be found desirable. In the same paper it is noted that the Manchester City Council Gas Committee will attend and give evidence, not for the purpose of placing any obstacles in the way of a full development of the electric light, but simply to safeguard the interests and property of the corporation. The Leeds Corporation have appointed a deputation to proceed to London with the town clerk, and support the Government measure. The Convention of the Royal and Parliamentary Burghs, held in Edinburgh, agreed to the motion that "The Convention memorialise Her Majesty's Government to introduce into their Bill in Parliament for the amendment of the Electric Lighting Act, 1882, a clause to provide for the protection of the interests of local authorities by requiring the undertakers, when such undertakers are not local authorities, to give security for the payment of all necessary costs incurred by local authorities in connection with applications for provisional orders, and to lodge such security prior to the serving of the notice provided for by Clause 4 of the said Act." The motion was agreed to. At the meeting of the Association of Municipal Corporations, held at the Westminster Palace Hotel last week, the Mayor of Salford, Mr. J. Farmer, in the chair, the three Electric Lighting Bills were considered, and the report of the Law Committee thereon read and adopted. Sir G. Morrison explained that at a joint meeting of the Parliamentary and Electric Lighting Committees of the Leeds Corporation, held on the previous day, it was determined to support the Government Bill. He moved a resolution to this effect; and the meeting determined that a clause should be added, asking the Government to make the consent of a Corporation a condition precedent to a provisional order being granted to a company. The resolution was seconded by the Town Clerk of Birmingham (Mr. E. O. Smith), and supported by several representatives of large bodies. Sir G. Morrison said during the discussion that had taken place an attempt had been made to attribute the failure of the electric lighting companies to the purchase clause of the Act of 1882. Several gentlemen of engineering eminence had told him that the real cause of the failure (apart from the reckless speculation which had taken place in electric lighting shares) had been the fact that electrical science itself had not yet advanced so far as to enable companies economically to supply large towns from a central station. The Borough Engineer of Leeds and himself had discussed the matter; and he thought it was not impossible that other modes of power (the essential factor in all electric lighting installations) which would facilitate the use of the electric light in large towns would be available, and practically render the functions of electric light companies worthless. The resolution was carried unanimously; and, on the motion of the Mayor of Huddersfield (Alderman Varley), it was unanimously resolved that the town clerks of Leeds, Nottingham, and Birmingham, and representatives from the Corporations of Liverpool, Manchester, Blackburn, and Sheffield, be requested to give evidence in support of the resolution of the Association before the House of Lords Committee appointed to consider the Bills.

RING ARMATURES AND THEIR GENERAL PROPORTIONS.

BY GUY C. FRICKER.

In the following investigation into the best proportions for ring armatures, square cores will first be considered and afterwards those of the cylinder pattern with the view of making a comparative study of their respective merits.

It will be seen at once that all dimensions of either ring may be expressed in terms of $\sqrt{a}$, a being the area of cross section. Thus, referring to Fig. 1, we may write

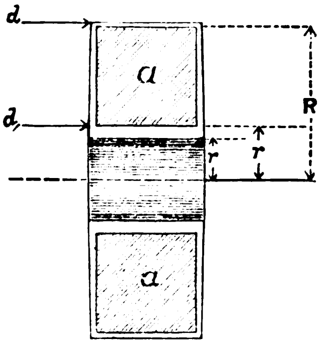

FIG. 1.

R = radius from centre to circumference $= (q+1)\sqrt{a}$,
r = „ „ inside of core $= q\sqrt{a}$,
r = „ „ „ winding $= x\sqrt{a}$,
d = depth of winding outside ring $= s\sqrt{a}$,
$d_{\prime}$ = „ „ inside „ $= (q-x)\sqrt{a}$;

also, $$\frac{\mathrm{R}}{r_{\prime}} = \frac{d_{\prime}}{d}$$

that is, $$\frac{q+1}{x} = \frac{q-x}{s},$$

whence $$x^2 - q\,x + s\,(q+1) = 0,$$

and $$x = \frac{q \pm \sqrt{q^2 - 4\,s\,(q+1)}}{2}.$$

The total E.M.F. generated in the coils of the ring may be expressed, as is well known, as follows:—

$$\mathrm{E} = \rho \,.\, \mathrm{M}\,a \,.\, \mathrm{N} \,.\, n \quad \ldots\ldots \quad (1)$$

Where M = magnetic density per unit of area in the core.
a = cross sectional area of armature core.
N = number of turns of wire round the ring.
n = number of revolutions per minute.
ρ = a "constant" converting into units of E.M.F.

Calling the number of layers on the outside of the ring l, the sectional area of the conductor (including insulation) α, and the width which each wire occupies on the circumference w, N may be expressed in the following manner:—

$$w = \frac{l\,\alpha}{d} = \frac{l\,\alpha}{s\sqrt{a}}$$

$$\mathrm{N} = \frac{l\,d_{\prime}}{d} \cdot \frac{2\,\pi\,r_{\prime}}{w} = \frac{l\,(q-x)}{s} \cdot \frac{2\,\pi\,x\,s\,a}{l\,\alpha} = \frac{2\,\pi}{\alpha} \,.\, x\,a\,(q-x).$$

Substituting this value in equation 1, and including all constants under ρ, we get

$$\mathrm{E} = \rho \,.\, \mathrm{M}\,x\,a^2\,n\,(q-x)$$

For purposes of comparison M may also be included under ρ, for whatever be the general proportions of the core the same magnetic density is assumed per unit of section. We can therefore write

$$\mathrm{E} = \rho\,x\,n\,a^2\,(q-x) \quad \ldots\ldots\ldots\ldots \quad (2)$$

Substituting for x and taking the + sign, we have

$$\mathrm{E} = \rho\,a^2\,n\left[\left\{\frac{q + \sqrt{q^2 - 4\,s\,(q+1)}}{2}\right\}\left\{\frac{q - \sqrt{q^2 - 4\,s\,(q+1)}}{2}\right\}\right]$$

$$= \rho\,a^2\,n\left[\frac{q^2 - \{q^2 - 4\,s\,(q+1)\}}{4}\right]$$

$$= \rho\,a^2\,n\,s\,(q+1) \quad \ldots\ldots\ldots\ldots \quad (3)$$

The negative sign in the value for x gives, in this case, an identical result for E.

The factor n in Equation 3 must vary of course with different diameters if a constant peripheral velocity is required; on the other hand, it may be necessary to keep the spindle speed constant, in which case

$$\mathrm{E} \propto a^2\,(q+1)$$

The first condition in comparing the proportions of similar types must be, of course, to keep the weight constant. Now the expression

$$\left(r + \frac{\sqrt{a}}{2}\right) a$$

evidently indicates a value proportional to the weight of the core, and this may also be written

$$a^{\frac{3}{2}}\,(q + \tfrac{1}{2});$$

thus when the weight is constant

$$a^{\frac{3}{2}} \propto \frac{1}{q + \frac{1}{2}}.$$

Now, when $a = m$, let

$$\frac{1}{q + \frac{1}{2}} = p,$$

then $$q = \frac{1}{p} - \tfrac{1}{2},$$

and $$q + 1 = \frac{1}{p} + \tfrac{1}{2},$$

and $$\mathrm{E} \propto m^2\left(\frac{1}{p} + \tfrac{1}{2}\right),$$

or $$\mathrm{E} = \rho\;m^2\left(\frac{1}{p} + \tfrac{1}{2}\right) \quad \ldots\ldots \quad (4)$$

Still including all constants under ρ. Now let

$$a = t\,m,$$

then $$\frac{1}{q + \frac{1}{2}} = t^{\frac{3}{2}}\,p,$$

and $$q + 1 = \frac{1}{t^{\frac{3}{2}}\,p} + \tfrac{1}{2},$$

and $$\mathrm{E} = \rho\,t^2\,m^2\left(\frac{1}{t^{\frac{3}{2}}\,p} + \tfrac{1}{2}\right) \quad \ldots\ldots \quad (5)$$

The results in 4 and 5 may be written,

$$\mathrm{E} = \rho\left(\frac{m^2}{p} + \frac{m^2}{2}\right),$$

and $$\mathrm{E} = \rho\left(\frac{m^2\,t^{\frac{3}{2}}}{p} + \frac{m^2\,t^2}{2}\right)$$

from which we see at o ice that E increases indefinitely with t.

Taking the other case of a constant peripheral velocity, the importance of making A large is still more marked, for

$$n = \frac{\mathrm{V}}{2\,\pi\,\mathrm{R}} = \frac{\mathrm{V}}{2\pi(q+1)\sqrt{a}}$$

V being the perpheral velocity.

Substituting this value for n in Equation 3 we have

$$\mathrm{E} = \rho \,.\, \frac{\mathrm{V}}{2\,\pi} \cdot \frac{a^{\frac{3}{2}}}{q+1} \cdot s\,(q+1)$$

$$= \rho \,.\, \frac{\mathrm{V}}{2\,\pi} \,.\, s\,a^{\frac{3}{2}}$$

And condensing constants as before

$$\mathrm{E} = \rho \,.\, a^{\frac{3}{2}} \quad \ldots\ldots \quad (6)$$

The above considerations show that cores should be constructed of great radial depth.

It is interesting to notice from Equation 6 that the effect of increasing the diameter of a core of any given area is simply to reduce the spindle speed at the expense of weight and efficiency, the extra winding on the armature doing nothing towards giving an increased output.

There is a way open, however, for increasing the output in such a ring, viz., by multiplying the number of poles in the "field." In some cases this may be considered a convenient method of developing the powers of a dynamo, but it is open

Digitized by Google

to serious objections. To illustrate this, take the case of two rings of equal weight, the one being twice the diameter of the other, and let them rotate in "fields" of two and four poles respectively at equal peripheral velocities.

For the sake of convenience call the small ring A, and the larger one, revolving in the 4-pole field, B.

Supposing an equal depth of copper to be on the outside of each ring we have, say, $\frac{N}{2}$ coils in series on A (N coils altogether), cutting Ma lines of force twice per revolution, thus

$$E = \rho\, 2\, M a n \frac{N}{2} = \rho M a n N.$$

On B, the conductor will be one-half the sectional area of that on A, because there will be four groups parallel instead of two; thus there will be N coils in series (4 N altogether), cutting $M\frac{a}{2}$ lines four times per revolution; but as this large ring will make but half the revolutions of A, the E.M.F. will still stand

$$E = \rho M a n N.$$

The lengths of wire will be as $\sqrt{2}:4$ respectively, but that on A being twice the size of that on B, the weights will be as $1:\sqrt{2}$, showing a saving of nearly 42 per cent. of copper in favour of A.

Instead of taking an equal depth of copper on A and B, it would be more correct to consider this dimension as bearing a fixed proportion to $\sqrt{a}$ as has been done in the first calculations; for the whole system of magnetic resistance being considered as $\frac{\text{length}}{\text{area}}$ it follows that for purposes of comparison we ought rigidly to adhere to this inverse ratio.

The areas in A and B are as 2 : 1, therefore the depths of copper should be as $\sqrt{2}:1$. The effect of this would be to equalise the weights of copper and at the same time raise the output of A . 42 per cent.

Certainly, when considered in the abstract, multipolar machines do not appear to advantage, the more especially when it is remembered that a similar excess of copper will be apparent in the field magnet coils.

It may be remarked that the ratio of $1:\sqrt{2}$ is that existing between the lengths bounding any given area when contained in one or two similar rectangular or circular figures, and it is natural that in the same sense in which it is wrong to make multiple magnetic circuits *outside* the armature, it is also a mistake to do so *within* it.

The first of these errors has been pointed out by Kapp and others, but, strange to say, the second, although identical in character and involving the first, has not hitherto been understood.

In passing on to the cylinder type machine, we are met by some little difficulty in choosing a common stand point from which to view both forms in an impartial, and at the same time

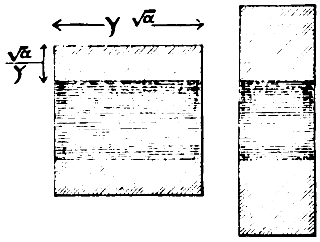

FIG. 2.

in a sufficiently accurate manner. It will, perhaps, be most convenient to consider the case in which the areas a in the two cores are identical; also the number of turns N, and the external depth of winding $s\sqrt{a}$; it will then follow that the inner annulus will also be the same size in each ring.

The length of wire in any case will evidently be

$$l = 2\,N\left(\gamma + \frac{1}{\gamma}\right)\sqrt{a},$$

where γ is the coefficient of $\sqrt{a}$ as shown in the diagram. The value for γ will gradually diminish as the core is shortened, becoming unity in a square core.

The surface speed of the square core will be greater than that of the cylinder for the same number of revolutions in the ratio, as

$$q + 1 : q + \frac{1}{\gamma};$$

but from the nature of its construction the square core would be able to run at a higher surface speed than the cylinder, chiefly on account of the spindle being shorter and there being so much less tendency for the wires on the periphery to swell out and become displaced. Practically speaking, for the case in point the spindle speeds may be equal for the same conditions of good working. The weight would be proportional to

$$\left(q + \frac{1}{2\gamma}\right)a^{\frac{3}{2}}$$

Thus the square core would be heavier by

$$a^{\frac{3}{2}}\frac{(\gamma - 1)}{2\gamma}.$$

A far more important point, however, is the relative polar surface in the two machines.

Taking m to represent the angular extent of the pole pieces in degrees, the surface on each side face of the square core would be

$$\text{Surface} = \frac{m\pi}{360}\left[\left\{\sqrt{a}\,(q+1)\right\}^2 - qd^2\right]$$

$$= \frac{m\pi}{360}\left(2\,q\sqrt{a} + a\right).$$

the top surface being

$$\frac{2\,m\pi}{360}\,(q+1)\,a.$$

Multiplying the surface for one side face by two, and adding all up, we have

$$\text{Total surface} = \frac{m\pi}{180}\left\{a\,(q+2) + 2\,q\sqrt{a}\right\} \quad . \; . \; (7)$$

In the cylinder there is only top surface to be considered, and this will be equal to

$$\frac{m\pi}{180}\left(q + \frac{1}{\gamma}\right)\gamma a \quad . \; . \; . \; . \; . \; . \; . \; (8)$$

The value for γ at which the expressions in 7 and 8 will be equal is

$$\gamma = 1 + \frac{a + 2\,q\sqrt{a}}{a\,q}.$$

The general tendency in cylinder machines is to make $\gamma = 2$ and $q = \cdot 5$ or thereabouts; thus it will be seen that the total polar surface comes very far short of what it would do in a square core of the same area. Taking the above values for q and γ, the comparison for the two cores in question would be as follows:—

Cylinder core.			Square core.
$5\,N\sqrt{a}$	= length of wire on armature	=	$4\,N\sqrt{a}$
n	= number of revolutions	=	n
$\frac{3}{4}\,a^{\frac{3}{2}}$	= weight of core	=	$a^{\frac{3}{2}}$
$\frac{m\pi}{180}\,.\,2\,a$	= polar surface	=	$\frac{m\pi}{180}\left(2\cdot 5\,a + \sqrt{a}\right)$

Taking $m = 120$ degrees

$$\frac{m\pi}{180} = 2\cdot 09;$$

thus we should get in cores of 25 square inches sectional area, 104·5 square inches polar surface on the cylinder, and 141 square inches on the square core.

The 35 per cent. in favour of the square core here shown is a very important point, because it means a greater magnetic density, and consequent greater output. Still there are, no doubt, other considerations concerning weight and size which may commend the cylinder pattern in the judgment of many engineers of large experience.

PROF. HUGHES'S INAUGURAL ADDRESS.

The following is an abbreviation of certain "Critical Remarks on the last Discoveries of Prof. Hughes respecting the Self-Induction in Metal Conductors," by H. F. Weber, of Zurich, as given in the *Centralblatt für Elektrotechnik*, No. 8, 1886.

The author says: "Hitherto the self-induction constant of every non-magnetisable metallic conductor has been regarded as a quantity whose value depends entirely upon the form and geometrical dimensions of the conductors, and consequently as entirely independent of the material of the conductor. Only for magnetisable conductors did the theory of electro-dynamics hitherto allow the material of the conductor to have any influence on the induction-constant. A magnetisable conductor will be circularly magnetised by passing a current through it, and this magnetisation greatly increases the induction-constant of the conductor, just as the iron core increases the coefficient of self-induction of a coil to an enormous extent. Prof. Hughes has arrived at quite other results. He found that the constant of self-induction of every metallic conductor (carbon included) is dependent on the material nature of the conductor, and varies in an extraordinary degree with the metal." The author then goes on to give some results from Hughes's paper, and continues:—"The theory hitherto held of the kind of dependence of the induction-constant (coefficient of self-induction) on the form and dimensions of the conductor has for a long time been developed formally in a completely general manner. From this development it may be deduced that the induction-constant of a long, thin, straight, stretched wire, with a circular section, and of the same diameter throughout has the form

$$Q = 2l \left\{ \log \left(\frac{2l}{e} \right) - 0{\cdot}75 \right\}$$

where l denotes the length and e the radius of the wire. If the wire is magnetisable, and if its magnetic moment increases proportionally to the magnetising force, its induction-constant (coefficient of self-induction) has a somewhat different form; then it becomes

$$Q = 2l \left\{ \log \left(\frac{2l}{e} \right) - 0{\cdot}75 + \pi k \right\}$$

where k is the coefficient of magnetisation.

"In accordance with this the induction-constant of a fixed length of such wire decreases in a logarithmic manner as the thickness increases. Prof. Hughes has made very searching measurements on the dependence of the induction-constant of rectilinear stretched wires on their thickness. These measurements gave him the universal result that the induction-constant of such wires depends on the thickness of the wire in such a manner that this constant has the smallest value for the smallest thickness, that it increases with the thickness, reaches a maximum value, and then again decreases." The author then goes on to give results from Prof. Hughes's paper, and says that the important contradictions which thus arise between theory and experiment demand a critical inquiry to ascertain on which side the error lies. He says:—"The following lines are to demonstrate that the causes of this contradiction are founded on a faulty interpretation which Prof. Hughes applied to his measurements, and that these contradictions disappear as soon as the results of the measurements are indicated in an appropriate manner." The first thing to which he objects is the measurement by the sonometer. Prof. Hughes has considered the effect proportional to the angle through which the second coil was turned to produce silence in the telephone. Now the effect is far from being proportional to this angle when the coils are of nearly the same size or the angle large. For a small coil at the centre of a very much larger one the effect is proportional to the sine of the deflection, and only in this case and when the angle is very small may the effect be taken as proportional to the deflection.

"Again, the effect itself does not depend alone on the induction-constant of the wire. If we take the coils and the range of effect so that the angle of deflection is proportional to this effect, we obtain for Q_1, the self-induction constant of the wire under consideration.

$$Q_1 = P_1 v + \left\{ P_1 v \left(\frac{1}{w_4} + \frac{1}{w_3} + \frac{1}{w_2} + \frac{Q_2}{w_2} + \frac{2l_3}{w_3} \log \left(\frac{l_3}{l_4} \right) \right) \right\} w_1$$

where w_1 is the resistance in this wire, v the angle of deflection, Q_2, Q_3, &c., the self-induction constants of the other wires, w_2, w_3, &c., their resistances, and l_2, l_3, &c., their lengths. P_1 is the mutual potential of the two coils when the two are parallel and one much smaller than the other." The author says that the term involving w_1 will, in certain cases, be far greater than the term $P_1 v$, and it is proportional to the resistance of the wire whose induction constant is to be measured. The neglect of the second term accounts for the curious results arrived at by Prof. Hughes.

Again, in respect to Prof. Hughes's experiments with wires of different metals, but of the same form, the author says he has lately made experiments, after the manner of Prof. Hughes, on wires of the same length and thickness, but of different metals (non-magnetisable ones), and then calculated the induction constants from the mathematical formula, and he could detect no difference in those constants.

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

The first of a series of three lectures on the electrical conditions of the human body was delivered by Dr. Wm. H. Stone, F.R C.P., in the Royal College of Physicians on Thursday, the 8th April. The Vice-President occupied the chair.

Dr. Stone: Mr. Vice-President, brother Fellows, and gentlemen—Before I commence this lecture I feel it incumbent upon me to thank the president and the fellows of this old and venerable society for allowing me the use of this library. I must also thank them for allowing me to issue more than the usual number of invitations to scientific friends who are not immediately connected with the medical profession. There are many who have materially helped me in this investigation, which has now lasted for five years, and to them I must also return my sincere acknowledgments, especially to Mr. Gregory, to the professors of Cooper's Hill, to Dr. Lodge, of Liverpool, to Mr. Lant Carpenter, the son of my old and respected teacher, Dr. Carpenter, and last but not least to Prof. Hughes, the distinguished discoverer of the microphone. Having thus delivered myself of my gratitude, allow me to begin by saying what these lectures are not going to be. They are not going to be lectures on the so-called medical electricity. Medical electricity is a term of ill omen; and, indeed, it is incorrect. Hitherto the application of electricity to the human body has not come up to the expectations which are reasonable in the case of so powerful a force. It is evidently in embryo—in a state of origin; and it has come into use in medicine in a somewhat oblique, and somewhat accidental manner. It is a good physiological stimulant, a good test of muscular irritability, and in this way it has been taken up, more in a physiological than in a physical light. Besides this, it has suffered grievously from misrepresentation. We see every day in the papers the statement that electricity is life. Now, this is most undoubtedly untrue. No doubt we shall some day be able to find a closer relation between electricity and life, but at present we are not justified in making this statement. What I am going to endeavour to do in the three brief hours allotted to me is to establish certain physical conditions with regard to the human body, and to apply them perhaps in a simpler manner—in a more natural fashion—than has been done by previous investigators, more from the inorganic, more from the physical than from the physiological side. Very early in the history of electricity physiologists seized upon it, and very properly—distinguished men like Du Bois Reymond—and used it as a means of causing irritation in nerve and muscle. The galvanoscropic frog, which is a very delicate test of a current, and the employment of the induction coil, have to a certain extent kept back the physical investigation of how a current acted. The galvanoscopic frog is too delicate a test. It is an unmeasureable test. It responds, without our being able to know, to very small excitements, and the induction coil is a very complicated electrical apparatus, the actual working of which has been hardly fathomed by physicists. We have lately been able to find an apparatus which will to a certain extent supersede the galvanoscopic frog, and we are beginning to get at the root of the action of the induction coil. What I have to say more about the induction coil I shall reserve for the third and last lecture—on induction currents generally. Now I will only show you how we can replace the galvanoscopic frog by a telephone, and so find out more than we know about the currents that pass from the induction coil. I have a Du Bois Reymond coil, and I have laid on an electrical wire along the room to a series of telephones, and when I put the battery on I shall be able to make the telephones respond, jump and jerk, as does the electroscopic frog [Experiment.] Now, if you take any of these telephones from the wall you will find that it is responding to the secondary current of the induction coil. If I now withdraw the secondary coil it gets softer and softer; but if you put it up to your ear it can be heard when the primary is a long way from the secondary. I shall revert to this in the third lecture; but I wish to show you that the telephone can be used with induced currents as a galvanoscopic frog. The first discoverer of this fact was Prof. Hughes, the discoverer of the microphone. Now, I propose to occupy myself in the short time at my disposal to-day with the resistance of the human body. The first investigation of this kind does not begin, alas! with me. It occurred to many of the early observers that the human body must place some obstacle in the course of an electrical current which is technically termed resistance. Volta worked himself at it. He did not fully work it out, and we have a number of early observations by distinguished electricians. Volta, Humboldt, Lenz, Bertholon in 1736, Gilbert in 1801, Pschlmnikoff, Feschenes in 1839, Edward Weber and Wm. Weber, his brother, at Gottingen in 1835. I have an account of them in a magnificent work of Du Bois Reymond, but time will not allow me to quote from it. The best work among the early writers is undoubtedly that of Du Bois Reymond on the resistance of the uninjured human body. But all those early investigations upon the electromotive state of the living uninjured human body turned out unsatisfactorily. Even Du Bois Reymond himself, good man as he was, seems to have given it up in despair. He says in this very treatise which I have translated: "In no part of this province do we meet with such unaccountable freaks of experiment. To prove the most insignificant fact often calls forth efforts out of all proportion, and whilst in other cases the discovered contrivances have lasted for a long series of experiments, we are now in the position that almost every single experiment demands preparations which, if not complicated, yet necessitate detailed preparations whereby those experiments are the

Digitized by Google

most lengthy one can imagine." I will not read more of it, but he goes on to speak of the errors in them, and finishes up by saying that the error of all those early experiments is so great (he names Volta and Humboldt) on account of what I shall name presently—on account of polarisation that those investigations, made in part carefully, but without great searching, are deprived of value through the circumstance that the polarisation of the electrodes was not taken into consideration. There is another reason why these early investigations failed entirely, that is that both Weber and those who followed him seem to have taken it for granted that it was an indifferent matter whether you measure the resistance of the human body with the ordinary constant current or battery—of low tension ; or whether you take the high tension secondary induced and momentary current from an induction coil. I believe I may claim to myself the small merit—if merit it be—of having found that the resistance of the human body with the ordinary battery current and with the induction current is totally different. With an induction coil I shall be able to show you it is very often only half—seldom more than two-thirds—what it is with the ordinary battery current, and I fear that the induction current used by Edward Weber, and ever since by observers of this phenomenon, must be discarded as untrustworthy. There are so many cases to be met with that it cannot be taken as it stands. There is also a very good paper by the Count du Moncel, which is what I may call the first approximation to a real estimate of the resistance of the human body. It is, indeed, a wonderfully good paper on the conduction of moderately good conductors, of imperfect conductors, in which he says, towards the end :—"The conductibility of the human body, although acting very much like those we have spoken of, presents certain peculiarities." And then he describes his experiment. "I employed electrodes of platinum, which I tied pretty strongly on the internal wrist of the patient"—or rather the lady patient, for it was his wife, who is still alive. Then he gives a description of the experiment, which lasted an hour and a half. Only by an unfortunate error, without intending any harm, he decomposed his patient. He electrolysed her, and the poor old lady still bears the traces on her wrists of a tremendous ulceration which he produced by his experiment. Count du Moncel has gone to his rest, but she remains to this day with scarred wrists, so that the professor made a great error through this electrolysing, though he got an estimate approximating to the real resistance of the human body—that is to say, the body of his own wife. He said it was equal to about 350, and sank to 220 kilometres of telegraph line. In those days there was a unit used in Switzerland and France which was called the French unit, a kilometer of iron wire such as was used for the telegraph, and he used very small electrodes. This kilometre of iron telegraph wire was four millemetres in diameter, so it may be taken practically as 10 ohms. Therefore, his estimate of the resistance of the human body was, say, 3,500 to 2,000 ohms—a very wide margin, but the latter figure approximates to what it really is. He destroyed the epidermis and caused ulceration, and it is remarkable that he could not get much lower than that. Now, what is the reason of the difficulties that have existed? The moment I began to experiment I saw that there were two if not three. The first is the difficulty of making a good contact, and up to lately there never has been a proper contact made. The electrodes used by Count du Moncel were only 4½ centimetres by 3 centimetres—that is, 1¾ inch—by 1⅛in. English measurement, and the proof that they were not large enough, that the density through the current was great, was that they produced physical injury. The difficulty is, first of all, in making a good contact. The human body is somewhat like a condenser or cable, as I have said. It is a mass of conducting material contained in a highly insulating envelope. The skin is such a remarkably good insulator that it can be made to excite frictional electrical effects by the dry soles of the feet. For example, we heard lately a story of an electric boy who, simply sliding with his feet on a carpet, could produce sparks from his person. But any body may slide along a carpet in the same way and light the gas from the sparks produced. That was the secret of the story of the electric boy. Then, secondly, comes the fact that the human body rapidly electrolyses. The human body, I shall be able to show you in the second lecture, is a secondary battery of no inconsiderable power ; and when a current, even a small current, passes through it, electrical decomposition is set up, which is reproduced in an antagonistic current, and which modifies entirely the measure of the resistance. Besides that there is a third action, and that in the syllabus I sent round to the Fellows I name electro-chemical-capacity. In a paper I read before the the British Association I spoke of the human body as a condenser. So rapid is the progress of science now that I think I must modify that term. Prof. Hughes, whose brilliant researches are well known, furnishes me with a far better name for that third condition of the body which gave me so much trouble, by calling it *self*-induction. That, again, I must leave to a later lecture. Now as to the contact and the mode of investigation. It is obvious that any contact or resistance through the skin must as far as possible be eliminated. We do not want to know the resistance of the skin. The resistance of the skin can go up to any amount. It is given by the latest writer on electro-therapeutics, Dr. Rosenthal, as 8,000 to 20,000 ohms. What we want to know is the resistance of the tissues which underlie this insulating layer. Dr. Rosenthal has gone at great length into the different conditions of the skin, but the whole thing seems to be unnecessary. The physiological conductivity of the deeper tissues, not of the mere skin, is what we want to measure, and the plain statement is that the contact should be infinitely large, mathematically considered, compared to any current which may be sent through it. If this condition is complied with the resistance can be brought down to something very moderate indeed. I must employ, therefore (and I find I have been anticipated in this as in many other things by Du Bois Reymond), what fortunately succeeded with me, and what I lighted upon more by accident than otherwise, and that is salt and water. I tried, of course, other things ; but thinking of lead as an inert body, I used two large leaden poles, and those have answered. If the patient is confined to bed, I place a little salt water solution on his feet or hands, and I wind a bandage round the wrist. In this way I get a good contact. When I have my contact it is important, in the next place, if I am to measure the resistance, that I should take anatomical points so as to make sure that the same part, the same proportion of the patient is being traversed by the current in every case, and I have found two very convenient indeed. One is the prominence of the ulna at the wrist, which is marked in most people, and the other is the external malleolus of the ankle. The advantage of this is that when the patient is stripped you can raise the arm so [shown], and you can get a measurement of the human conductor, certainly within a-fourth of an inch. Therefore, these are the two points I commonly use for measuring. I have used in my experiments in most cases Wheatstone's bridge, but time will not allow me to go into a description of it. As regards batteries, I need not occupy any time ; any battery which is easily managed with a tolerably good electromotive force will do. I am in the habit of using a chromic acid battery, and these, when they are in good working order, may be said to have an electromotive force of two volts each. Their internal resistance is so small, compared with that of the human body, that you can neglect the internal resistance of the battery. I may say that I tried some other methods of producing contact, but they were more or less unsatisfactory. Besides, they hurt the students very much, and so I had to come back to the large leaden contacts. In addition to that I have to ask in what direction do we want to test the current ? There are four principal directions through which it is worth while passing the current. From hand to hand has been commonly used, but from foot to foot involves the largest quantity of tissue, and therefore is the most interesting. You may pass it through limited parts of the body, but, usually speaking, from foot to foot and hand to foot will give you a very good estimate of the resistance of the main tissues of the body. The lecturer then referred to the following results he obtained by experiment :—

		Conductor.		
	ft. in.	ft. in.	foot to foot.	foot to hand.
Mr. Todd	5 6	5 9¾	945	1,320
Mr. Shackel	6 3	7 0	930	1,027
Hungarian Giant..	7 6	8 7	930	1,032

He then said. Let me here remark that I find that it is in the legs principally that tall men differ from short men—not in the trunk or arms so much. I have had an opportunity of measuring a large number of persons of varying heights, and some of these—two or three of the most remarkable—I have put down in the diagram before you. My colleagues here will recognise in Mr. Todd an old clinical clerk of mine. You will see he is 5ft. 6in. in height. He measured 5ft. 9¾in. of human conductor. Mr. Shackel was also my clerk, and was quite a young giant. He was 6ft. 3in. in height, and he gave me 7ft. of human conductor. The Hungarian giant was an Austrian soldier, who was brought over to this country and was said to be 8ft. high, but after a careful measurement I found he was only about 7ft. 6in. when stripped of his externals, and from his external malleolus to the ulna he gave me 8ft. 7in. of human conductor. This is the largest case I have had the opportunity of measuring. Now as to the method of proceeding. The first method I have put down on the syllabus is momentary contacts. [Experiment.] I have, in circuit, a Wheatstone bridge of rather a particular form, and I have a commutating key so as to send the current in two opposite directions ; and I have a double contact key which I will put in contact with the battery, and afterwards through the galvanometer. In this way I thought I was lessening the effects of polarisation, and in that way these observations were taken, and they agree with one another very fairly indeed. This is a demonstrating galvanometer, and if I put on two compensating resistances the galvanometer shows it. [Experiment made showing the resistance to be 1,160 ohms.]

Now, the reason why I have recourse to these alternating currents is what I mentioned before as the second difficulty—that of polarisation, which causes the resistance to rise steadily. This polarisation is really chemical decomposition taking place inside the body, and it acts as an opposition—an opposing electromotive force. For a long time I was very much troubled in this way. I could not get any readings that would agree with one another. Indeed, Du Bois Reymond seems to have been embarrassed in a similar fashion, and ends without giving a figure showing the resistance of the human body. He says, in short, "I have not taken the trouble to ascertain the resistance of the human body." By this phrase I really think he means that he was not able to get any congruous readings. When I read my paper to the British Association, at Southport, my friend, Dr. Oliver Lodge, of Liverpool, whom I have already named, said, "Why not use Kohlrausch's principle of an induced current from an induction coil, and use the telephone as a galvanometer?" The method is extremely pretty and charming, and upon that method I spent a year's work. This instrument [showing it] is Kohlrausch's induction coil. It is a very neat little piece of mechanism, and here you can read from this scale [showing it] what the resistance of the body is ; but it came out entirely different in every case. The discrepancy was so enormous that it was obviously due to some error in the experiments, or some fault of the instrument. This is the method by which Weber tried to find it out. The results differed as much as from 1 to 2, or 1 to ½. I may now go on to speak of other methods which were suggested to me. Momentary contacts I have mentioned, alternating currents I have left for the third lecture, but I have still to speak of the second method of Sir Henry Mance, and with that I hope to solve the difficulty without recurring to alternating currents. Sir Henry Mance, as he now is, is superintendent of the Persian telegraph system, and on May 8th, 1884, he brought before the Society of Telegraph Engineers—of which I have the pleasure of being a member—a method of eliminating the effects of polarisation and earth currents from fault tests. It is a very technical

Digitized by Google

thing; but it amounts to this that a cable which is not acting well and in which the insulator has failed, is liable to set up a counter-electromotive force similar to that which I have named and which I shall presently demonstrate as occurring in the body. The body very much resembles a faulty submarine cable, and it occurred to me that this method might succeed better than the one I had wasted so much time on. I found it answer extremely well, and I was very much assisted by Sir Henry Mance, who wrote me the following letter: "I shall be very pleased if my method is of any assistance to you. I made a few experiments myself in that direction, but had no leisure to continue the investigation. From hand to hand I found the resistance was 900 to 1,100 ohms. The observation of the resistance was higher in consequence of polarisation. But I always corrected the results by my formula. I did no more than test one or two individuals for a couple of days, so I have no *data* of any value." Now, what is Sir Henry Mance's method? I have it here on the diagrams, and I have the whole apparatus, and a very beautiful apparatus it is, set up before you. This, as made by Latimer Clark, is a peculiar form of Wheatstone's bridge, which he uses. It can be done with the ordinary Wheatstone bridge, and I have done it with it. It is very much better to do it automatically here, because it requires very quick changes in consequence of the inconstancy of the resistance. It amounts to this that instead of cutting the currents as short as possible to stop polarisation, you let polarisation do its worst, and then you alter the conditions of the problem. [Experiment.] Mance's method against polarisation, used originally on the Persian Gulf cable, is:—

Let $R = R$ of coil A $\quad R_2 = R$ of coil B

$R_1 = R$ with coil $R_1 \quad R_2 = R$ with coil R_2.

Then
$$X = \frac{(R_1 \,.\, P_2) - R_2 \,.\, R_1}{R_2 + R_2 - R_1 - R_1}$$

or
$$X = \frac{A - B}{C.}$$

This is a complicated looking formula, but it really is not very difficult, and it can be made much more simple. Now I will endeavour to take a test on this method. Here I have my proportional coils. These two proportional coils are united to a cross piece, so that I can switch off at one motion. [Experiment shown, giving the resistance of the man's body operated on as 1,170 ohms.] Sometimes resistance rises, sometimes it falls. It is very difficult to say beforehand which way the polarisation will set, but I find it generally rises. That enables me, then, to go back to my diagrams, and to speak about what the actual resistance of the human body is. There is a very good diagram there made independently of me, in which volts are given at one side and amperes are given at the other, and the electromotive force was steadily increased so as to show the effect of it. The first two experiments were made by Mr. Lant Carpenter, and his able assistant, Mr. Wilkinson, and I prefer to put them down, for the reason that they are made by other observers. The third was made by me on the same patient some time before, and you see the agreement is most satisfactory. What I want to draw your attention to is merely the resistance from foot to foot. It began with 1,194, and went up after four minutes from counter electromotive force to 1,230 ohms, and then four cells were put on, and they seemed to break down the resistance. The diagram was as follows:—

	E M F. Volts.	Resist. foot to foot. ohms.	Current amperes.
First experiment...	2	1st minute R=1944	...... ·0016
		4th ,, R=1230	
Second experiment	4	4th minute R=1155	.... ·0031
Third experiment.	8	1st minute R=1130	.... ·0069
		4th ,, R=1160	

I think that these three experiments, considering that they were taken by different observers and at different times, may be considered to be very congruous indeed. Then there comes what is one of the most interesting points in the whole matter—that this resistance of the body is infinitely less than has been before thought. The question has been asked me, "But does not the size of the patient make a difference?" If a patient be healthy and well nourished and his muscles in good condition, it does not. We get traces of a very distinct physiological law, which I have named in the syllabus, that as the length of the lever—the mechanical law, as is the length of the bony levers—so will be the bulk of the muscles that move them, and so it appears in those three men of very different statures. All these men were active vigorous men, and, oddly enough, the smallest man gives the largest resistance by a little. [Diagram omitted.] From foot to foot you will notice there is only 945 against 930, and the Hungarian giant, who had been a soldier in the Austrian army and trained to military exercise, gave exactly the same figure as Mr. Shackel, who, I believe, was equally athletic. A difference comes out from foot to hand, where the difference is rather more marked. You have to pass through a very narrow conductor. Therefore I test with a larger bulk of the lower extremities. You notice the resistances come out very nearly alike—only five ohms difference. This point is, from a physiological point of view, of some value and importance. I cannot say that this law is universal. I do not claim that. In disease, in extreme illness, or in extremely fat people, in affections of the tissues, of course considerable differences take place. But in ordinary health you may say that the height does not materially modify it.

Now I have the last few minutes that remain to me to draw my conclusions from the question of the resistance of the human body. We must not calculate, as lately we have been doing a great deal too much, upon the safety of currents merely from the insulating power of the epidermis which may be accidentally broken down by so trifling a matter as saturation with salt and water. And many of those sad accidents at the International Exhibition and elsewhere are undoubtedly due to the fact that for a moment the insulating power of the skin gets broken down, and a strong current passes. On these subjects, a gentleman who has written a very excellent book, Mr. Cunynghame, has some very good facts, and he has written me a letter. He has been taking the resistance of the human body, and although he finds between two hands immersed in acidulated water 2,000 ohms, he draws my attention very explicitly to the facts. He says:—"May I suggest that there is one aspect of the question which I hope you will see your way to treat—that is, the real limits of safety for dynamos as to the electromotive force and intermittency. The subject has never been adequately treated, and the Board of Trade are much at sea on the question, particularly with regard to the limits of safety." They at present put down 200 ohms as the outside limit to be allowed, but many dynamos go up to 800 ohms, and there can be no doubt that, as familiarity breeds contempt, there will be more unfortunate men who will put their two hands on the brushes of a dynamo and suffer sudden death. At present the accidents are more serious than we know of, because I am afraid there is a trade coalition to keep them concealed. As physicians it is our duty to expose this and to stand out against it. It is thought that it would injure the future of the electric light commercially if these accidents were to be admitted and explained away, and so they are hushed up by giving compensation and presents, &c. Besides that I have a word or two to say as to what is pretty certain to be found—the alteration of resistance in disease. I have had a case which shows that this inquiry is not unpractical. It has given me great trouble to discover it, and I cannot say I have settled the point to my own satisfaction whether the human body acts as a fluid conductor or a solid conductor. The Count du Moncel and Du Bois Reymond believed it to be a fluid conductor. I am doubtful of this. The heat observations I have been able to make go the other way, solids and fluids are altered oppositely by a difference of temperature. In a case of dropsy, when the body gets waterlogged there is an enormously reduced resistance. Then I find that degenerated tissues and tissues where muscular fibre has been replaced by common fibrous tissue become infinitely less resistent. Muscle is not so good a conductor, and these differences are such large quantities that I do not think the observation can be accidental or instrumental. I had six cases of hemiplegia tested, and in all those cases the hemiplegic side resisted less; the fibrous tissue was a better conductor than the side on which the muscle was sound. In one case the difference was 420 ohms, in another 350, in another 360, in another 120, in another 550, and in another 730, all in the same direction. These surely cannot be all wrong; there would be some evidence of its being an instrumental error. I think we may take it for granted that paralysed muscle conducts better than healthy muscle. I am able to say besides, that certain metallic impregnations do influence the conductivity of the body. I have had the opportunity of testing, in cases of mercurial impregnation, lead impregnation, copper impregnation, and I have been working hitherto unsuccessfully with silver impregnation. With the first three I have succeeded. The lead is not very marked. In one case of copper impregnation I found that the right hand with which the coppersmith works his hammer, and the right side of which was impregnated more with copper than the other, conducted considerably better than the left hand, which he did not use much in his trade. In that case I was able to complete the observations by examining the urine, and from that urine, as a proof that it was impregnated with copper, I extracted 3 milligrammes of copper, which was analysed and weighed afterwards. The point of temperature I am hardly prepared to speak with certainty upon; but I have recorded the actual figures in a very curious case of ulcerative endocarditis, where I was able to test, during the paroxysms of fever, the sinking and rising of resistance, until death finally took place, and I found that when the body was hot resistance instead of being less was greater. But it is very seldom that an opportunity arises where one can with humanity make such an observation as this, and I am waiting for another case where I can do it justifiably. Here I may leave off for to-day, and will deal with the rest of the subject in the next two lectures.

(*To be continued.*)

*** Pressure on our space compels us to leave over to our next issue the continuation of Prof. Forbes' lecture, letters from several correspondents, &c.

CRIMINAL CARELESSNESS.—An accident, causing the death of a workman, occurred recently at Philadelphia. From the report of the accident in our contemporary the *Electrical World*, it would seem to be the result of the most criminal carelessness, and it is a great pity that the person who played so idiotic a part and switched on the current cannot be punished for his gross negligence. The report says:—"Daniel Coyle was instantly killed while making an electric light wire connection in front of Joseph Bell's shoe store, at 1,116, North Second-street. The electric lamp had set fire to the awning, and Coyle, who was in charge of the dynamo room at the Northern Electric Light Company's works, was despatched to attend to the wire, which was out of order. The electric current was shut off on that circuit, and he was at work on the bulkhead of the show window, making the temporary connection, when some one shouted from the pavement that the current had been turned on again. Coyle remarked, 'If they had let it alone a minute longer I'd have been done,' and toppled over with a groan on the awning. Young Bell, who was near him at the time, caught hold of his limp body and attempted to raise him, but receiving a violent shock, desisted. The senior Bell and others on the sidewalk promptly raised a stepladder and lowered the body, which was taken to an adjoining drug store, but found to be lifeless."

ELECTRICITY IN MINES.

The final Report of the Commission on Accidents in Mines, issued last Saturday, loses some of its interest by being so long delayed, and also, perhaps, to some extent, by its recommendations having been forestalled or foreshadowed in preceding reports. Nevertheless, the inquiry, which has extended, we believe, over a period of seven years or more, has resulted in the accumulation of a vast amount of evidence and information which will be of immense service in giving a wide publicity to the conditions of safety attending the working of mines, and in encouraging the adoption of precautions approved by an authority so high as that of the eminent scientists and practical men who were members of the Commission. No specific points for compulsory legislative enactments are put forward in this Report, but the basis for legislation is indicated in several places, should opportunity and occasion seem to justify it at some future time. But meanwhile we have no reason to doubt the cheerful willingness of the owners of mines to work them on the safest principles; and the utility of Parliamentary Commissions often lies quite as much in the suggestions they are able to make for voluntary adoption as in their proposals for more stringent legal regulations. This is peculiarly the case where an industry so varying in its conditions and circumstances as that of mining is concerned. Not only are there many different kinds of mines, but mines of the same kind have each their own distinct characteristics and consequent risks. To meet every one of these by general laws would be impracticable, and would probably, if attempted, do as much harm as good.

To investigate thoroughly the whole system of mining which prevails in this country, to call attention to defects in supervision, and to more especially trace out those obscure causes of accident which have hitherto eluded inquiry, are what a Commission like this was peculiarly well qualified to do; and it has certainly not disappointed our expectations. It is chiefly in relation to the last-named subject, however, that we have studied the Report with much interest. It will surprise many people that although mining accidents on a large scale are usually due to the ignition of explosive gases, the aggregate number of casualties from this cause is only 22 per cent. of the whole. The remainder are due to miscellaneous causes which appear to be inseparable from mining operations at great depths; but it is noticeable that 41 per cent. are caused by falling of material from the roofs and sides of the excavations, and are we venture to think, traceable to deficiency of light, or, more exactly, might be avoidable if the workings were more efficiently lighted. These figures happily show that great benefits have been already derived from improved ventilation and the employment of delicate gas indicators in recent years, and that risks from the incursion of firedamp are gradually diminishing. As regards the avoidance of accident by having a good light, the Commission makes the following observations:—"The advantages in point of convenience and efficiency which attend the employment of electric glow-lamps for illuminating the pit's bottom and roadways immediately adjacent to it have already been demonstrated at several collieries where this utilisation of the electric light has been combined with illumination at the surface by arc lights. In applying electric glow lamps to underground illumination, to the extent indicated, through the medium of conducting cables leading from the generators to the pit bottom, it is essential to safety, as well as to the permanent efficiency of the installation, that the cables should be placed in positions where they are thoroughly protected against possible accidental injury. It is also essential, in all mines where firedamp has been known to occur, that the glow lamps should be excluded from direct contact with the air of the mine in one or other of the ways indicated in this Report. Portable, self-contained electric lamps have been devised which will furnish for several successive hours a light considerably superior to that of the best safety lamps, and which at the expiration of eight hours and upwards will still give a light fully equal to that of a freshly-lighted Davy lamp." It is added that the progress recently made in the construction of portable electric lamps affords promise of a speedy utilisation of such lamps to an important extent in coal mines.

Of course these lamps do not afford any indication of the condition of the atmosphere, and their use must, in most cases, be supplemented by firedamp indicators and safety lamps. Our own belief is that in the improvement of these two last-named appliances, both of which have now nearly reached perfection, lies the miner's chief immunity from explosion, always provided that the efforts to maintain ventilation are in no way relaxed. For exploring, and similar purposes, the glow lamp is invaluable. We should be glad if the miner could and would work with it and a portable battery affixed to his person; but we do not expect it, at all events not at present. We think, rather, that a wider extension of the lighting of the workings by means of the glow lamps, adequately protected, would lessen the ordinary dangers of his position, increase the amount of work he is able to perform, and enable him to do it with greater ease and comfort. The defect of the lamp as a gas indicator constitutes its great merit as a light giver, being subject to none, or nearly none, of those risks which attend the use of even the best pattern of safety lamps. For it should be borne in mind that the presence of explosive gas is not of itself dangerous to life. The investigations of the Commission have, it is true, brought out the startling fact that a very small percentage, as little as two per cent., of fire-

Digitized by Google

damp is an element of extreme danger in certain conditions. But such small proportions of firedamp can be more easily detected by gas indicators than by the ordinary but dangerous method of a lamp flame. Moreover, if the gas, even in these slight proportions, is travelling at a rapid rate and accompanied by coal dust, the presence of an oil lamp rather enhances the danger of the situation. Hence, on many grounds, the substitution of more permanent illumination by means of the electric glow lamp for the ordinary miner's lamp would greatly reduce the normal risks, and, moreover, would allow of working in atmospheres which are at present unworkable.

One of the chief dangers, however, attending mining operations is the presenee, already referred to, of coal dust in what are called dry mines. This coal dust, impregnated with a little marsh gas, forms a mixture as inflammable as gunpowder, and is, of course, in the highest degree dangerous when shot-holes are being exploded for blasting purposes. Should the charge, instead of bursting inwards, blow itself out of the shot-hole, a considerable body of flame is projected "as from the bore of a gun;" the dry coal dust is ignited, and the most serious consequences may ensue. "If," says the Report, "a blown out powder shot occurs in a locality where the atmosphere contains a small proportion of firedamp (even not above two parts in 100 of the air), the presence of dry, fine, and porous dust, even if it be only comparatively slightly inflammable, may give rise to the explosive propagation of flame to distant localities, where either accumulations of inflammable or explosive gas-mixture (as in goaves or old working places), or deposits of very inflammable dust, may take up the explosion and still further extend its disastrous effects."

To the proper construction and management of these shot-holes a good deal of attention has therefore been given by the Commission; and one of their recommendations is that electricity should be preferred for exploding the charge. The firing of the ordinary miner's fuze is a dangerous operation of itself, and may give out a flame sufficient to ignite the surrounding atmosphere. Their use is condemned in this Report, and the use of electricity advised in the following terms:—

"Electrical exploding appliances present very important advantages from the point of view of safety over any kind of fuze which has to be ignited by the application of flame to its exposed extremity, as the firing of shots by their means is not only accomplished out of contact with air, but is also under most complete control up to the moment of firing. Their simplicity and certainty of action have been much increased of late years, while their cost has been greatly reduced, and but little instruction is now needed to insure their efficient employment by persons of average intelligence. For the foregoing reasons the use of electrical arrangements for firing shots in mines, where the employment of powder for blasting is inadmissible, should be encouraged as much as possible."

THE IRISH DEBATE AND THE CENTRAL TELEGRAPH OFFICE.

Probably at no period of the world's history has there been in a given time so great a dissemination of news as has been the case during the discussion of Mr. GLADSTONE'S Bill on Home Rule. The actual facts impress those who understand the nature of the work far more, we should imagine, than those who are altogether ignorant of the first principles of telegraphic communication. It will be unnecessary, therefore, to do more than tell our readers the facts of the case. On Thursday, the 8th of April, it may be stated that the number of words signalled from London was 1,500,000, the greatest number signalled on any previous occasion being 860,000. It will be seen from these figures that very little more pressure was required to have doubled the record. The apparatus used in dealing with large quantities of news is the Wheatstone automatic, and no less than 100 Wheatstone perforators were brought into operation on this occasion. Of these 30 were of the kind which punch six slips simultaneously, 13 were of the kind which punch three slips simultaneously, 31 were of the kind which punch two slips simultaneously, and 26 were single slip perforators. The amount of writing performed by the reporters may be estimated when we mention that the number of sheets of "flimsy" dealt with in the Central Telegraph Office on this single evening was about 15,000.

The figures so far are impressive enough, but they give merely the words signalled from London. In many cases one wire from London serves several offices, so that the same message which is signalled from London is read by each of these offices simultaneously. For example, there are wires from London which work simultaneously to Birmingham, Manchester, and Liverpool. A thousand words transmitted, therefore, upon this line are equivalent to three thousand words received—that is, a thousand each at the places named. The work on the subsequent evenings of the debate, though not so great as on this special occasion, was extremely heavy. The total number of words signalled from London on the evening of the 9th inst. was about 600,000. The number signalled on the 12th was about 504,000, and the number signalled on the 13th inst. was about 500,000. As we have said previously, the figures speak for themselves, and no credit which may be given to the Post Office officials is more than they deserve in carrying such work through without a moment's delay. We doubt if there is any other office in the world that would have been equal to such a demand.

CORRESPONDENCE.

PROF. HUGHES' RECENT EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On the 28th January of this year, Prof. D. E. Hughes, as the newly-elected President of the Society of Telegraph-Engineers and Electricians, read as his inaugural address a paper entitled "The Self-Induction of an Electric Current in Relation to the Nature and Form of its Conductor."

I regret that I was unable to be present at the reading of the paper, or on any of the evenings that were devoted to the discussion of the same; but, if I understand Prof. Hughes's meaning, the object of his paper is to prove that conductors of different metals and of different forms vary in their resistance in accordance with the nature of the electrical conditions under which they are placed. For instance, the resistance of a conductor would be different for a permanent current to what it would be for intermittent currents, the amount of the difference depending on the form of the conductor, *i.e.*, whether solid wire, strand, or ribbon, or a combination of two or more such conductors.

The apparatus for his experiments consisted of a specially constructed induction bridge in which the galvanometer was replaced by a telephone, and it was found to be impossible, however accurately the wires were balanced for a constant current, to silence the telephone when intermittent currents were passing in the battery circuit. If the galvanometer be used, a perfect balance is obtained, both with constant and intermittent currents. In Prof. Hughes's arrangement the sound of the telephone can only be reduced to a minimum; consequently, to produce silence he sends through the circuit counter currents produced by electro-dynamic induction, and

Digitized by Google

then again alters the length of the wire in circuit until no sound is heard in the telephone, and the true resistance of the wire is supposed to be thus ascertained.

The counter currents are set up by two bobbins of wire, a primary and a secondary one, the primary being in the battery circuit and the secondary in the telephone circuit, so that, by altering the relative position of the two bobbins, variations in the currents of the telephone circuit can be produced.

Now, some very remarkable results appear to have been obtained with this novel combination of an ordinary Wheatstone bridge and the professor's "induction balance," and from these results Prof. Hughes lays down the following startling propositions for the guidance of the practical telegraph engineer and electrician :—

"A solid rod of iron is the worst possible form for a lightning conductor."

"The conductor, if of copper, should be of ribbon form, or, if of iron, of numerous stranded wires, or a wide ribbon of similar conductivity to that of the copper."

"That there is a remarkable difference in the resistance of a wire during the 'stable' and the 'variable' period, or, in other words, with the results obtained with a constant current or intermittent currents."

"An iron wire has with rapid currents *more than three times* the resistance during its actual work than that supposed to be its true resistance."

"The more rapid the contacts of a telegraphic instrument the greater will be the difference between copper and iron."

"A solid iron wire is unsuitable for telegraph instruments requiring extremely rapid currents."

"Copper would reign supreme if it were not for the fact that stranded iron wires have greater rapidity of action than copper."

Now these propositions which I have quoted are so opposed to all my experience that I at once put them to a simple but, I think, efficient practical test.

A circuit was made up of an astatic mirror reflecting galvanometer, a battery of one Grove cell, a rapid interrupter, and a strand copper conductor of about 250 yards in length insulated by suspension in the atmosphere.

The intermitter was so constructed that from one hundred to two thousand interruptions of the current could be made per minute.

The internal resistance of the battery was ·2 of an ohm, and the resistance of the galvanometer ·1, whilst the resistance of the conductor was 1·07 ohm, so that the total resistance of the circuit was 1·37 ohm. Under these conditions the deflection of the galvanometer was obtained, both with a constant current and with rapidly intermittent currents. The wire under test was then removed, and conductors of different metals and forms substituted for it, each conductor having identically the same resistance—viz., 1·07 ohm, as measured by Wheatstone's bridge, and it was found that, whatever the nature and form of the conductor, the deflection obtained on the galvanometer was the same, showing that the resistance of a conductor of constant section and material is directly proportional to the length and inversely proportional to the area of its cross section, or in, other words, inversely proportional to the weight per unit length, and that whether it is carrying a constant current or intermittent currents. It therefore follows that, having ascertained by well known laws the resistance necessary to carry a desired current, it matters not electrically of what metal or form the conductor is made. Of course I am referring to aerial wires for telegraphic purposes or for lightning conductors. For the conductors of submarine telegraph cables, of course these remarks would not apply, but that has nothing to do with the present case. Having satisfied myself in the matter I took no further notice of it, thinking that the erroneous impressions Prof. Hughes had conceived were of such a nature that he would soon discover his mistake, and immediately take means to rectify the same. But, now that I find the subject is likely to be re-discussed, I think it well to publish the results of my experiments, which prove, to my mind, that Prof. Hughes has been misled in endeavouring to obtain reliable results by a combination of electro-dynamic, electro-dynamic-inductive, and electro-magnetic-inductive currents, without a due regard to the laws which govern the same.—Yours, &c.

April 12, 1886. WILLOUGHBY SMITH.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The "Writer of the Article," whose letter you print on page 435 of your last issue, does me the honour of entering upon fresh issues, and, before the points that I have raised are settled, challenges me to discuss with him whether or not the general argument which he put forward on page 391 in your issue of March 26, demolishes Profs. Ayrton and Perry's theory of the constant-current motor, as set forth on pp. 453-454 of my treatise.

Your readers will perhaps not be surprised at my declining for the present to favour the writer with my opinion on the matter. I shall be happy to do so as soon as the points already at issue have been settled—not before.

And I take this course for two reasons. *Firstly*, that I am not going to allow the writer of the article to draw off on another scent until the actual point at issue is settled. *Secondly*, because the point still at issue, and which is the second of those raised by me in my letter of March 5 (p. 331), is a question of correct or incorrect definition; and it would be absurd to discuss any problems involving definitions until the definitions themselves are settled.

The two points originally raised by me (p. 331) were :—

(1) That the writer of the article was wrong in using the number 736 instead of 746.

(2) That the writer of the article was using the term "critical speed" in an incorrect sense—in a sense different from that in which it is used throughout my treatise, and, before me, by others whose authority in this matter has never been questioned.

The writer of the notice has since admitted that he was wrong on the first point. I was under the impression, from his letter of March 26, p. 391, that he had virtually given in on the second point, because he there says :—"Even accepting his (*i.e.* my) latest definition, I cannot help thinking that the term 'critical speed' is ill chosen. I should prefer to call it the proper working speed, *for it is that speed at which the machine will do what is claimed for it by the term self-regulation.*" The italics are mine. I italicise the words because if that is what the writer of the article means by his term "the proper working speed," it is—and he ought, if he had really read the book he was reviewing, to know it—precisely the same thing as that which I and others before me have consistently and persistently called "the critical speed." I have no authority to speak for M. Marcel Deprez, or for Prof. Ayrton, or for Prof. Perry, or for the others who have used this term for the past four years; but I should be surprised if they consent to change their definition at the bidding of a critic whom the courtesies of journalism leave anonymous, and who thinks it "ill-chosen."

When, therefore, in his review this writer went out of his way to declare that "a motor has no critical speed," alleging as the reason that it is not self-exciting, I wrote to you to point out that the writer was using the term "critical speed" in a different and incorrect sense. I thought I had made it quite plain in my letters that the term "critical speed" has nothing to do with the limiting speed of self-excitement, but refers to the speed at which the machine is self-regulating; and I thought further that, when the writer of the article so far relaxed as to say on p. 391 that he preferred to give the name "proper working speed" to that which everybody before had called the "critical speed" (though he thinks it ill-chosen), there was some chance of our agreeing as to facts, while possibly preferring our own names for the facts.

But the writer's last letter rudely dispels any such hopes, for he now turns round and says (p. 435) :—"To prevent any possibility of misunderstanding, I again repeat that no motor and no dynamo which is not wholly self-exciting can have a critical speed." Indeed! It is a magnificent assertion; but, unfortunately, it is not correct, unless he means by "critical

Digitized by Google

speed" something very different from the meaning usually attributed to that term. What does the term critical speed refer to? It can only refer to one of two things:—

(*a*) The speed at which the dynamo or motor will do what is claimed for it by the term self-regulation.

(*b*) The speed below which the purely self-exciting dynamo refuses to excite itself.

If "critical speed" means (*a*) then I am right.

If "critical speed" means (*b*) then the writer who makes the above positive assertion is right.

It is simply and solely a question as to which is the definition. Does the term "critical speed" refer to the least speed of self-excitation or to the speed of self-regulation? That is the only question now open between us. I distinctly decline to enter upon any other topic until it is settled which of these two is the accepted definition amongst electricians, and I would request you, Mr. Editor, kindly to umpire this question as to what the fact is.—Yours, &c., SILVANUS P. THOMPSON.

THE ELECTRIC LIGHT AT LLOYD'S.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit us to thank Mr. Bernard Drake for his correction. No other information was before us than the paragraph referred to, which, of course erroneously, speaks of "the introduction of storage cells" as subsequent to, and consequent upon, the complaint of noise. The statement that the belts run "perfectly silently" shows that we were right in questioning the use of the words "driven direct," and this was the sole object of our letter.—Yours, &c.,

PRIMARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am endeavouring to elucidate the present condition of electric lighting by means of primary batteries. For this purpose I am collating information concerning them with a view to publishing the result in connection with a book I am engaged on.

At present the subject is clearly in the realms of the unknown, and I should be very glad if those of your readers who are able to furnish any reliable data would kindly communicate with me as under. The testimony of manufacturers as to the excellences of their batteries is not solicited. I am already acquainted with the value of their superlative hyperboles.

The information I am anxious to obtain is—

Have any primary batteries been successfully employed for two years—if so, where, and for how many lamps?

The same questions as applied to one year's working, or even again for, say, eight months?

What is the largest number of lamps now worked from a primary battery, and for how long has it been in operation?

Again, can any places be named in England where primary batteries have been working over, say, eight ten candle-power lamps successfully for six or eight months?

By successfully I do not mean economically. We have not come to that yet. The question of cost is in this case only of secondary importance, and I am first desirous of locating any instances of primary batteries giving a *steady constant current nightly* for any period over six months.

I do not wish to exclude "damaging" information, as this is also of importance; and although I fear voluminous accounts could be written on this head, I should be glad to hear of any personal experiences of your readers.

It is only by inquiries such as the above that really reliable facts can be tabulated, and, therefore, such information will be of value, and highly esteemed by—Yours, &c.,

JNO. B. VERITY.

Moorcroft, Weybridge, April 10, 1886.

REDUCTION IN CABLE TARIFFS.

The Eastern Telegraph Company notifies that on July 1st the following reductions of tariff will take effect, viz.:—

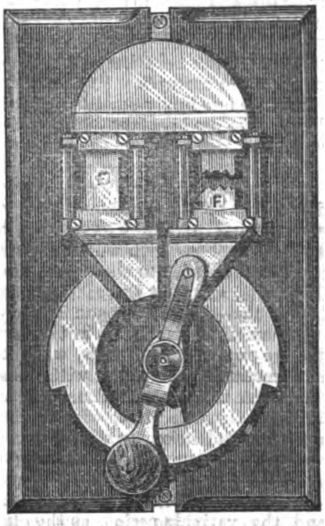
		s.	d.		s.	d.	
To India	From	4	7	to	4	0	per word
,, Hong Kong, Amoy, Foochow, and Shanghai	,,	8	4	,,	7	1	,,
,, Other places in China	,,	10	0	,,	8	9	,,
,, Macao	,,	8	9	,,	7	6	,,
,, Manila	,,	10	0	,,	9	0	,,
,, Cochin China	,,	7	9	,,	5	8	,,
,, *South Australia	,,	10	8	,,	9	4	,,
,, Spain	,,	0	6	,,	0	4½	,,
,, Portugal and Gibraltar	,,	0	6½	,,	0	5½	,,
,, Malta	,,	0	8	,,	0	7	,,

* The rates to other colonies in Australasia are not yet fixed.

Negotiations are in progress which, it is hoped, will be concluded in time to allow of reduced rates for Press messages exchanged with Egypt, India, and Australia to come into force on the same date.

BAILY AND GRUNDY'S CUT-OUT.

The illustration of this instrument almost explains itself. This design has been made to remedy a defect in the older forms, so that when necessary no delay may arise from the fusing of any foil. It will be seen that the arrangement is for



Baily and Grundy's Cut-Out.

two foils to be placed in the instrument, and if one is accidentally fused, all that has to be done is to take the switch, bring the other into circuit, and the whole thing goes as before. The spoilt foil can be replaced when convenient.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

Pressure on our space compels us to hold over the Report of the Discussion on Mr. BERNSTEIN'S Paper on "Low Resistance Glow Lamps," which took place on Thursday, the 7th inst.

PROF. HUGHES ON SELF-INDUCTION OF AN ELECTRICAL CONDUCTOR.

The following is an advanced proof, with which we have been favoured, of the remarks Prof. HUGHES would have made in reference to the discussion of this paper, but which he has preferred to put in writing:—

We have had a long and most interesting discussion, and I desire to express my warmest thanks to Lord Rayleigh, Mr. F. L. Pope, Prof. Forbes, Dr. Hopkinson, Mr. W. H. Preece, Dr. Fleming, Mr. FitzGerald, Prof. Silvanus Thompson, and Prof. Ayrton, for their most kind appreciation of my researches. They have all recognised the enormous influence which self-induction exerts, and the necessity of studying the phenomenon in all its effects. There have been some points raised which are important, but to which I must reply as briefly as possible, as I am anxious to bring forward the results of some further researches, which of themselves will answer many of the questions asked.

Digitized by Google

Lord Rayleigh, while fully recognising the importance of the subject of my researches, seems not to have seized all the details of the method which I have employed, or the meaning of some of the terms which I have used. Prof. Forbes has already replied to that portion of his remarks; but in his communication dated February 24 Lord Rayleigh assumes that "the disturbance depends upon the rapidity of vibration, so that, in the case of of ordinary mixed sounds, silence can be attained only approximately." Prof. Silvanus Thompson has also asked me if the results depend on the rapidity of the contacts. In reply, I must state that in point of fact the rapidity of the contacts has no influence on the result, providing they are not more rapid than the rise and fall of the extra currents. Let us suppose that, instead of rapid contacts, we make and break the contact once only per minute, then, on making or breaking the contact, we shall hear a single blow or tap on the telephone; and if the communications of the bridge and telephone are arranged for the *stable* period, this sound will not be heard when the resistance of the bridge is perfectly adjusted. Suppose that we now change the communications so as to observe the *variable* period, still making and breaking contact but once per minute, we shall then find (if there is self-induction taking place in the wire under observation) that we have no longer silence at the previous adjustment of the bridge; if this disturbance is due only to the extra currents, we can reduce it to zero by throwing in from the sonometer an opposite momentary secondary current of *equal* value; but if the disturbance is due only to the resistance being changed, then we shall have to move the slide on the bridge until we have again perfect silence. In many cases we have to deal only with the extra currents, in others there is a far greater change in the resistance of the wire than in the force of the extra currents. Both can be adjusted separately or alone, but no change of the resistance slide will compensate for the induced currents, nor will any change of the sonometer affect in the slightest degree the required adjustment of the resistance slide; it is the first portion of the current that we are measuring by means of the telephone, or its action at the moment of making or breaking contact.

The object of my researches was to observe what takes place at the first instant of contact. To this the telephone responds with admirable precision, whereas, as I have already said, a galvanometer would be useless for such delicate experiments as I have made, where it is necessary that the self-induction of a few inches of straight wire may be readily perceived and accurately measured. The rate of speed of contacts, therefore, can be increased up to the point where the duration of the contacts is at least as long as the duration of the extra currents. In short wires the duration in time of the extra currents is exceedingly small, and much less than any duration of contact that I have used; a large electro-magnet would require a lengthened contact and a different method. The only advantage, therefore, of short contacts is the constant repetition of sounds or beats, enabling us the more readily and rapidly to find the required balance. All of the important points mentioned in my paper have been verified by independent methods, and they have also been repeated with slow and rapid contacts, as well as with widely different external resistance in the battery circuit; but I wish to show that the induction bridge gives perfectly reliable results, and that its readings can never be changed or misunderstood. I have chosen a fine German silver wire for the resistance bridge, because German silver has (even in the form of large wires) an extremely low inductive capacity; and this, when the wire is fine, is again reduced to a mere fraction as compared with what it would be in wires of 1 millimetre diameter of different metals. To test the instrument, place a piece of similar-sized German silver wire in the arm A B; we do not then find any trace of self-induction, as all the four arms of the bridge are equal; we may vary its resistance by shortening the length of the wire, but the bridge can only then be adjusted to zero by moving the resistance slide. Under these conditions there is no difference perceived between the stable and the variable period, as the changes produced are equal on all sides. Let us now replace this German silver wire between A and B by a copper wire of the same resistance, we then find that the stable period gives exactly the same zero as previously, but that a disturbance takes place in the *variable* period, and that this cannot be adjusted by the *resistance* slide, but that it is completely reduced to zero by the opposed induction current of the sonometer. Again, if we heat this same wire, its resistance is changed, and can only be compensated by moving the resistance slide; if we make this wire into a loop or a parallel return, there is no change in the resistance, but the *self-induction is reduced* at once, as shown by the sonometer; winding this wire in a coil increases the induction, and, within certain limits, we may perceive no change in its resistance, whilst its *self-induction has increased* several hundred per cent. Now, suppose we increase the resistance by heating and the induction by coiling the wire, we have then two distinct effects of known values, and the measurements given by the resistance slide and by the sonometer are precisely those which would have been given by either when measuring them separately; and this again proves that where we have a case of change of resistance it can only be met by adjusting the resistance slide, and where we are measuring the electromotive force of the extra-currents they can only be compensated for by the use of the sonometer. The cause of the extra or momentary increased resistance of a wire during the variable period can be explained. The current, on entering the wire, produces an extra-current of an opposite name, and that this really opposes the passage of the current is proved by the upsetting of the previously balanced bridge; there is, in fact, in this moment less resistance on the opposite side, and the balance can only be restored by the resistance slide.

There are, however, cases where this effect is entirely reversed, in which there is less resistance in the variable than in the stable period; this occurs when we are testing extremely fine wires with powerful currents, for the steady current heats the wire, thus introducing an extra resistance, which does not take place to the same degree with short contacts as in the variable period; but, as I have already said, care must of course be taken to avoid all such sources of error; and if we understand the subject, and know exactly where to look for errors, there should be no difficulty in constructing a bridge perfectly free from experimental error. The instrument and method which I have employed have a great advantage over any previously used, as from the exquisite sensibility of the former we are enabled, not only to verify all the results obtained by previous observers from their experiments on coils, but to do that which no other instrument or method has previously enabled us to accomplish, viz., to observe the self-induction of straight wires and the laws of its reactions (as in the contiguous portion of the same current in straight wires and sheets) entirely separate and distinct from the mutual reactions of one part of a coil upon another. These I have shown to be quite different, as an iron coil has less self-induction than a copper one, whilst in straight wires the reverse is the case. We must not neglect this all-important point, for in no way do my researches contradict well-known results, they simply go further, and show the physical reasons for certain phenomena; and where theory has failed to predict, or previous experiments to show, this has been due simply to the fact that no instrument existed sensitive enough to record or measure the effects which take place in the self-induction of a comparatively short wire free from external reaction.

Self-induction in coils has been a subject which I had of necessity to study in relation to my printing telegraph instrument. The movement of my armature being extremely rapid produced extra currents of sufficient force to trouble other instruments on the same line. I finally vanquished this difficulty in 1860 by an arrangement whereby the armature in rising instantly short-circuits its own electro-magnet, and by mechanical means (peculiar to the instrument) is entirely separated from the line, placing the line at the same time direct to earth or battery, but leaving the electro-magnet open, so that the return of the armature produces no extra currents that can affect the magnet or line. This has answered perfectly, and has been in use on all of my instruments since 1860 up to the present day. I have also used, since 1851, divided coils, whereby the current is passed through both coils in parallel, and not in series; this I use on lines less than 500 miles, not simply because of the diminished resistance, but because I found from experiments much less disturbing influence from the extra currents. I have, however, lately, by the aid of the induction bridge, been not only enabled to measure this difference, but to trace it to its true cause, and the following table gives a representative result obtained from numerous coils of different sizes and resistances, and with or without iron cores:—

Coils formed of 3 metres Silk-covered Copper Wire, 1 mm. in diameter, each Coil being 5 centimetres diameter.	Comparative Force of the Extra Currents.
One coil alone	100
Two similar coils in series	174
Two similar coils in parallel, but separated 5 cm. from each other	55
Same two coils in parallel, but superposed	81
One single coil of thicker wire of exactly the same form, length, and resistance as the two coils in parallel	75

The table shows an increase of force when two coils are in series, but not quite double, as a portion is reduced by the increased or added resistance. This is a well-known effect; but an interesting result is shown where the two coils are parallel and separated, giving then 32 per cent. less induction than the same coils superposed, and also 25 per cent. less than that of a single coil of precisely the same resistance. We can easily explain this, and trace the effect to the reactions of contiguous coils on each other. I have shown a remarkable difference in the inductive capacity of different metals when formed into wires of the same diameter; and as the order follows that of their respective specific resistances, it became an interesting study to know what would be the result if all the wires were of the same length and resistance. It is necessary to employ the same length, as the induction increases with the length; consequently a copper wire, compared with a brass wire of equal resistance, and therefore of greater length, would show a great difference in their inductive capacities. There are, however, several methods, free from experimental errors, which I have employed in this investigation. If we take wires of different non-magnetic metals of the same length and diameter, and reduce them to the same resistance by an added resistance comparatively free from induction, such as carbon, I find that there is apparently no difference whatever in the inductive capacity of the different metals, all (yet tried) giving by this method very nearly the same result; but in this case we have added an external resistance, and thus prevented any difference of action due to the different density of the current in metals of high and low resistance. If, instead of an added external resistance, we take wires of the same length and resistance, but of different diameters, we then find a marked difference in their inductive capacities; for instance, a pure copper wire, compared with a brass wire of double the diameter, shows a marked higher force in the copper wire. We might naturally believe that the brass wire, from its larger diameter, would give higher results than the smaller copper wire; but if we have thoroughly seized the importance of the phenomenon which I have demonstrated of the reaction of contiguous portions of the current on each other, we can easily prove that the larger the diameter of the wire the less will be its proportionate reactions, so that, whilst the resistance decreases directly as the increase in section, the reactions of the currents upon each other become *less* as the diameter increases, the resistance diminishing as a straight line, whilst the induction would follow a curve similar to that shown in the diagram.

The following table shows the electromotive force of the extra currents

Digitized by Google

on wires and strips 1 metre in length, a chemically pure copper wire of 1mm. diameter being taken as the standard of 100, to which all the rest were compared :—

Wires of the same diameter, but of different resistance—1 metre in length.		*Wires* of the same resistance, but of different diameters—1 metre in length.	
Soft Swedish iron............	500	Soft Swedish iron............	400
Copper	100	Copper	100
Brass	65	Brass	88
Lead	50	Lead	81

Strips of the same width and thickness, but of different resistance—1 metre in length.		*Strips* of the same resistance and thickness, but of different widths—1 metre in length.		
12 mm. wide, $\frac{1}{10}$ mm. thick.		$\frac{1}{10}$ mm. thick.		
Copper	60	12 mm. wide	Copper ...	60
Brass	48	42 ,, ,,	Brass......	45
Iron...............................	45	72 ,, ,,	Iron	39
Lead	35	96 ,, ,,	Lead	29

In the above table, wires of the same diameter follow in the order of their resistance, iron alone being the exception; the same order is preserved in wires of the same resistance but of different diameters. In the latter case there is a nearer approach to equality, but they still show a difference of from 12 to 19 per cent., and whilst the non-magnetic metals have increased their inductive capacity with increased diameter, iron has fallen 20 per cent.; consequently, wires of different metals of the same resistance have not the same inductive capacity, owing, I believe, to the action of contiguous portions of the current, as I have already shown. If we reduce the extra currents by employing thin sheets or strips, there is in the case of iron a still more remarkable difference, for in strips of different metals of the same width the force of the extra currents in iron is actually less than that of brass, and if we compare an iron strip with an iron or copper wire of the same resistance, we have iron wire 500, copper wire 100, and the iron strip 45, or actually 55 per cent. less than the copper wire. In the case of wires a nearer approach to equality in inductive capacity is shown when they are of the same resistance, but in strips this is reversed, for here, when equality in resistance is produced by wider strips, the difference becomes greater, iron then having actually less inductive capacity than a lead wire of the same resistance. This extraordinary result must be due, not only to the reactions of contiguous portions of the current being less in sheets or strips than in wires, but also from an imperfect formation of the circular magnetism which takes place in all iron wires on the passage of an electric current. This, however, is only a partial cause, as we can obtain a still further reduction of the extra-currents by employing numerous fine wires separated from each other, the circular magnetism in the latter case being perfectly formed in each wire; but we still have the maximum experimental reduction due to the separated portions of the current no longer acting on each other. Copper and all metals show a similar reduction when we separate the wires of a strand conveying a current, but when the numerous wires are brought close together, copper approaches in value that of a solid wire, whilst iron wires are but comparatively little influenced by their closer proximity. I have tried all forms of conductors, such as square, stellar, tubular, &c.; they all show a gradual diminution of inductive capacity as compared with those of a solid circular section; in a solid conductor the maximum effect being obtained in the circular section, and the minimum in that of a wide flat sheet. We can reduce the self-induction of any metal far below the comparative force that I have given by widening the strip, or, still better, by diminishing its thickness as we widen it, and it is evident that if we keep the same width and gradually increase its thickness, we then approach the conditions of a solid wire; consequently, where it is necessary that we should be able to utilise a given amount of copper in the best possible form, so as to convey a current of an enormously high tension but of short duration, as required in a lightning rod, we should widen the conductor as much as the mechanical stability and durability of the conductor will allow, and I believe that a lightning conductor of copper 1 mm. thick by 10 cm. wide would satisfy the mechanical requirements whilst preserving the physical conditions necessary for a perfect conductor.

My experiments have shown clearly that a solid iron rod is unsuitable for a lightning conductor; but we may use a stranded iron wire or a flat iron sheet of the same conductivity as the copper. The iron wires should be galvanised, as all iron wires coated with a non-magnetic metal show a marked reduction in their inductive capacity; and here, as well as in the ribbon form of copper conductors, practice has guided our inventors in the right path, for it is an almost universal practice to galvanise iron wires in order to preserve them, and ribbon copper lightning conductors have been gradually replacing the most objectionable iron rod, for which there can be no defence based on experimental or scientific reasoning. I have already given the results of a compound wire of copper and iron made by myself, but I have since (through the kindness of Mr. W. H. Preece) been furnished with some most admirable specimens of American compound wires, the copper being electro-deposited upon a core of steel wire, and also some specimens in which the core is of copper with a steel exterior. I have thus been enabled not only to verify my previous results, but to prove that an exterior coating of copper has a most powerful influence in reducing the self-induction of its steel or iron core, for, if we take a given length of this wire and compare it with a similar length and diameter of copper wire, and taking for comparison the copper as a standard of 100, we have only 107, or 7 per cent increase for the compound wire, but if we file off the copper so as to leave the steel core bare, the inductive value of this same wire rises to 350. In order to study this effect, let us place an iron wire in the interior of a closely fitting copper tube, and insulated from it. This has no effect upon the iron wire; but if we join the exterior copper tube to the interior iron wire at both ends, the current passes through both at the same time, and the inductive capacity of this compound system is reduced almost to that of solid copper, as previously observed in the compound wires. These effects can be fully explained when we reflect that the circular magnetism produced by the passage of an electric current through an iron wire is produced only upon the exterior portion of the wire, and cannot take place when this exterior is, as in a compound wire, of copper, consequently a steel or an iron wire coated with copper of sufficient thickness is entirely free from this magnetic reaction. Now, if an exterior coating of copper has such an effect in reducing the self-induction of its iron core, it follows that an opposite effect should be produced by coating a copper wire with iron. Experiments with this, and also with a copper wire inserted in a closely fitting iron gas tube, prove that the effect was as foreseen, viz., a remarkable increase in the inductive capacity of the wire.

One result, however, which I did not foresee, although it is clearly indicated in the experiments quoted in my paper, is that not only is the inductive capacity of the interior copper wire increased to a great degree, but that a copper wire coated with iron has a higher degree of self-induction than a solid iron wire; in fact, its inductive capacity is not only higher than is possible to obtain from the softest iron wire, but its *resistance in the variable period* is proportionately greater than any yet remarked in a solid iron wire. I have made numerous experiments on this subject, and they all show that whilst copper in a straight wire or a single *wide* loop has a far less inductive capacity than iron, it has, on the other hand, the property of being far more excited by the reaction of iron, so that a straight copper wire can be excited by this reaction to a degree greatly exceeding that of a straight iron wire under precisely the same conditions. I will cite a few experiments which illustrate this point. A copper and an iron wire of equal resistance, and 1 metre in length, were measured for their inductive capacity and resistance, the inductive capacity of the copper wire being as 100, as compared with 400 for the iron. The resistance of the copper in the variable period had only 8 per cent. increase, compared with 128 per cent. for the iron; but a great change took place when each of these was placed in the interior of an iron gas tube of sufficient diameter to allow of the wire being insulated. The force of the extra-currents in the copper wire then increased 350 per cent., whilst the iron increased but 8 per cent.; the force of the extra-currents being now for copper 450, against 433 for the iron. The influence of an exterior iron tube on the resistance of the wire during the *variable* period was still more marked. The copper wire, which without the exterior iron tube had only 8 per cent. increase, now showed 934 per cent. increase, or, by direct measurement, 1 metre of this wire, during the rapid rise and fall of the current as in the variable period, had precisely the same resistance as 10·34 metres in the stable period, or a much greater difference than I have obtained from an iron wire; for the iron wire insulated in the gas tube only showed an increase due to this tube of 22 per cent., giving a total of 178 per cent. difference, or by direct measurement, 1 metre of the iron wire with its insulated iron sheath, in the variable period, required 2·78 metres to balance it in the stable period; thus copper shows more than three times the sensibility to an exterior sheath of iron than an iron wire itself. Iron appears to be self-contained, and, as regards self-induction, comparatively less acted on by an exterior influence. This is well shown in the case of coils, where the induction of a coil of insulated iron wire is but slightly increased by its own reactions, or those produced by the introduction of an iron core, as in an electro-magnet, whilst copper coils with an iron core show a remarkable increase. We can thus easily obtain extra currents of ten times the electromotive force of those from an iron coil of the same length, resistance, or diameter; and the resistance of a copper coil, which in the stable period may be far less than that of an iron coil, can, by means of its increased self-induction from the reaction of its iron core, be greater than that of an iron wire coil. At first glance this may be considered unfavourable for copper; but we must remember that whilst copper, in the presence of iron, can be excited to a far higher degree than iron, and consequently has stronger extra currents and greater proportional increased resistance in the variable period, this is really a measure of the work it is capable of doing, for we are able by means of this property to obtain the high efficiency of transformation of energy as in the secondary currents. In point of fact, a dynamo machine having its electromagnet and armature wound with insulated iron wire would, irrespective of its resistance, have an extremely low efficiency as compared with those wound with copper; and as regards the resistance of either of these wires, there can be no doubt that the resistance of the armature of a dynamo, or, in fact, of any coil of wire as measured during the stable period, gives no approximate indication of what its *real* resistance is during the period in which it is doing work.

Table A, on next column, shows the influence of an iron tube surrounding a straight iron or copper wire, compared with compound wires.

The table shows that the iron tube has a much greater effect upon the copper wire than on the iron wire, the effect in both cases being at its maximum when the tube is insulated from its central conducting wire, for when the wire is in contact with its tube there is evidently a shunt action, or species of eddy current, formed between the outer coating and the central portion. This I have been enabled to measure by interposing the telephone between the inner core and the sheath, or, still better, by employing a double insulated sheath of iron or copper, and joining

Digitized by Google

them together at one extremity, the opposite ends being joined through the telephone; by this means we are enabled to measure the differential effects of the secondary currents generated in an inner and in an outer sheath. The table also shows the effect of joining the outer sheath at both extremities, thus allowing a true eddy current to form; this at once reduces the electromotive force of the extra-currents, but has but little effect on the differential resistance in the variable period. If, however, we place the wire in contact throughout, so that the effect from the centre to the exterior of each portion can at once be partially neutralised, then there is a marked decrease in its resistance; and if, as in a compound wire, the exterior coating is in direct and still more intimate contact with the inner core, we then have the maximum reduction. We can thus prove that the shunt effect, or partial neutralisation of the extra currents, takes place locally, and probably transversely. We see also, by its effect on the reduction of the resistance during the variable period, that the passage of an electrical current then takes place with less opposing resistance from the self-induction than could be the case if there were no internal partial neutralisation of the extra currents. No doubt this effect also occurs in sheets and strips, and has its influence in causing the remarkable reduction of self-induction that I have already shown.

TABLE A.

Wires and Iron Tube each 1 metre in length.	Comparative E.M.F. of Extra Currents.	Approx. comparative Increased Res. during Variable period.*
Copper wire, 2 mm. diameter alone ...	100	1·08
Same wire insulated in the interior of the iron tube	450	10·34
Same joined to the tube at both ends ...	275	10·00
Same in contact with the tube throughout its length	200	7·83
Compound wire (copper interior with steel exterior)	325	4·35
Soft Swedish iron, 2 mm. diameter, alone	400	2·28
Same wire insulated in the interior of the iron tube........................	433	2·78
Same joined to the tube at both ends ...	240	2·70
Same in contact with the tube throughout its length	215	2·60
Compound wire (steel interior, copper exterior)	107	1·20

* That of the Stable Period being taken as 1.

In conclusion, I once more desire to express my thanks to all who have taken part in the most interesting discussion that has followed the reading of my paper. Mr. W. H. Preece and Prof. Forbes, who have seen my experiments, have borne testimony to the truth and care with which I have carried out these researches; and our well-known American electrician, Mr. Frank L. Pope, has cited examples showing that the superiority of a stranded iron wire was noticed even in the early days of telegraphy, and that the superiority of a compound wire over an ordinary iron wire is a well-known practical fact in the United States. He has also cited a case similar to the experiments of Prof. Guillemin and myself, where an electro-magnet was destroyed by lightning, notwithstanding that the telegraph line was joined direct to earth in advance of the electro-magnet. I am glad that many of the results of my researches are fully borne out by the practical experience of the past; and I hope that those which have as yet not been foreseen in theory or applied in practice will receive the same attention and verification that all discoveries should undergo, as I feel convinced that their truth will become more and more evident when repeated in the laboratory or applied in practice.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS, APRIL 12.

ELECTRIC LIGHTING ACT (1882) AMENDMENT (NOS. 1, 2, AND 3) BILLS.

Lord MONSON moved that the following lords be named of the Select Committee :—Earl Cowper, the Earl of Camperdown, Viscount Bury, Lord Balfour of Burleigh, Lord Rayleigh, the Earl of Crawford and Balcarres, Lord Methuen, Lord Houghton, and Lord Lingen.

The motion was agreed to.

On the motion of the Earl of WEMYSS, Lord Bramwell and, on the motion of Lord HOUGHTON, Lord Wolverton were added to the Committee.

Some discussion arose, on the motion of Lord GRIMTHORPE, to entitle all petitions against these Bills, presented before the 15th inst., to be referred to the Select Committee; and to declare that the petitioners should have leave to be heard before the Committee; but it was decided to leave the discretion in this latter respect to the Committee itself.

PETITION AGAINST THE ELECTRIC LIGHTING ACT (1882) AMENDMENT (No. 3) BILL.

The following petition has been presented against this Bill and in favour of No. 1 Bill:—

To the Right Honourable the Lords Spiritual and Temporal in Parliament assembled. The most humble petition of the Electric Lighting Act Committee, sheweth as follows :—

1. Your petitioners were formed as a general committee on the suggestion of the Right Hon. Joseph Chamberlain, when President of the Board of Trade, to frame clauses in amendment of the Electric Lighting Act, 1882, and to confer with the Board of Trade as to the terms of provisional orders and licenses, and your petitioners claim to represent the commercial and scientific interests of the United Kingdom on the subject of electric lighting.

2. A Bill is now pending in your Right Honourable House under the above name or short title, whereby it is proposed to amend Section 27 of the Electric Lighting Act, 1882, by enacting that the expression "prescribed period" in that section, used in relation to the purchase of any undertaking or part thereof, shall mean such period not exceeding 42 years from the date of the passing of the Act confirming the provisional order or of the special Act authorising such undertaking as may be specified in that behalf in such provisional order or special Act; provided that where no period is so specified, the prescribed period shall be deemed to be a period of 30 years, and that no period exceeding 30 years shall be so specified in relation to the purchase of any undertaking or part thereof, except with the consent of the local authority within whose jurisdiction such undertaking or part thereof will be.

3. The practical effect of the said amendment will be to slightly extend the period after the expiration of which local authorities are, under the powers of the Electric Lighting Act, 1882, empowered to exercise an option of purchasing electric lighting undertakings within their district.

4. The effect of the said purchase option section in the Act of 1882, has been to deter capitalists from embarking their money on electric lighting undertakings, and virtually to stifle the development of the electric lighting industry in the United Kingdom, and your petitioners submit that any such option of purchase as is given to local authorities by the Act of 1882 cannot but have the effect of preventing the development of such industry, and that the extension of the period prescribed by that Act will not materially affect the question.

5. Your petitioners submit that it is to the general interests of the country, as well as to those of persons more especially interested in electric lighting, that a fair chance should be given to this industry of developing, and that the purchase option section of the Act of 1882 having been found to be a bar to all such development, it is expedient that it should be repealed, on proper provision being made for insuring that the interests of the public are duly protected, and your petitioners submit that this will be well effected by the provisions of a Bill now pending before your lordships, intituled the Electric Lighting Act (1882) Amendment (No. 1) Bill.

LEGAL.

The Bankruptcy of Bassano and Company.

In the Chancery Division of the High Court of Justice on Friday, before Mr. Justice Pearson, another question in the proceedings between the United Telephone Company and Messrs. Bassano and Slater came up for decision. The defendants were manufacturers of telephone materials at Derby, against whom the United Telephone Company had obtained an injunction and damages for infringement of patent. The costs amounted to £1,200, which the plaintiff Company endeavoured to obtain by levying an execution, and the sheriff seized the chattels on Bassano's premises in November. Previous to this, however, Bassano and Slater had executed a bill of sale to Miss Oakes of all the stock-in-trade and plant. She had taken possession, and was carrying on the business for herself, employing the present defendants as her servants, upon a weekly wage of £2 each. The day after the sheriff took possession Bassano and Slater presented a petition in bankruptcy, and a receiver was appointed. The question now for decision was whether the property belonged to the sheriff, the receiver, or Miss Oakes.

Mr. Micklem appeared for the United Telephone Company, Mr. Yate Lee for the receiver, and Mr. A. Cock for Miss Oakes.

The JUDGE decided that the bill of sale was void, as it did not comply with the requisites of the law affecting such instruments; but he acquitted Miss Oakes of any suspicion of not having acted *bonâ fide*. The goods were, he considered, in the apparent possession of the bankrupts at the time of the commencement of the bankruptcy, and, therefore, they belonged to the receiver.

COMPANIES' MEETINGS & REPORTS.

The Eastern Extension, Australasia, and China Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of this Company was held on the 14th inst. at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last general meeting, which were confirmed by the present meeting and signed by the Chairman as correct. The report of the Directors, which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN: Before putting to the meeting the resolution which I shall have to propose, I will, as usual, make some remarks on the report. I daresay you will all agree with me that the report is a very full and complete one. There is scarcely a detail connected with the working of the business in the last six months respecting financial matters which is not embodied in the report; but on an occasion like this—at these half-

Digitized by Google

yearly meetings—I think the more information we can give to the shareholders upon the general working of the Company the greater will be the confidence that will exist between the shareholders and the Board of Directors. The gross receipts for the half-year amounted to £247,017, against £248,087 for the corresponding period of 1884, or a decrease of £1,070. During the first part of the half-year the receipts compared very favourably with those of the corresponding half-year; but in November they began to fall off, and large monthly decreases have had to be reported ever since, as shown by the following figures:—In November, 1885, the receipts were £40,427, against £42,286 in the same month of 1884, or a decrease of £1,859, and in December, 1885, they were £34,785, against £41,426 in December, 1884, being a decrease of £6,641. In January of the present year our receipts were £39,699, while in the same month of 1885 they were £44,144, a decrease of £4,445; in February of this year they were £33,688, against £40,114 in February, 1885, or a decrease of £6,426; and in March of this year they were £37,804, against £46,193 in the same month of 1885, or a decrease of £8,389. These are important decreases, and no doubt you will probably ask me if I can give a reason why they should have taken place. I have often said at these meetings that trade influences our receipts very materially, and that war influences them to a very great extent; and the best explanation I can offer to account for this large falling off of revenue is that during the long period of depression of trade from which nearly all industries in the world have severely suffered, the Eastern and this Company were not affected as might have been expected, owing to exceptional causes, which have now ceased to operate, namely, the Egyptian campaign, to which New South Wales sent a contingent, and the more recent expedition up the Nile, which largely added to our traffic. There was also the Afghan frontier dispute, which led to a considerable amount of telegraphing all over our system, and consequently our receipts during 1884 and 1885 showed substantial increases over previous years when business was more flourishing. During the last few months, however, there has been no startling event to provoke the sending of telegrams, and we have therefore felt the effects of the general depression, from which we had happily so long escaped. This, I believe, is a temporary reduction. Telegraphy is certain to go on. Trade may be sick for a short time, but it never dies. With the revival of trade I expect to see a revival in our returns. The working expenses for the half-year have amounted to £71,473, against £79,496 for the corresponding period of 1884, or a decrease of £8,023, which is principally attributable to the smaller quantity of cable used in effecting repairs during the period under review. The net revenue for the half-year amounted to £130,185, against £124,228 for the corresponding period of 1884, or an increase of £5,957. Comparing the figures for the whole year, the results are as follows:—The revenue in 1885 was £506,493, while in 1884 it was £485,759, giving an increase of £20,734 for the year. The expenses for 1885 were £145,891, while in 1884 they were £146,154, showing a decrease of £263. One interim dividend at the rate of 5 per cent. per annum has been paid for the past half year, and another will be distributed to morrow, together with a bonus of 2s. per share, making a total payment for the year of 7 per cent. [applause]. The reserve fund has been increased during the half-year by £47,818, and now stands at £565,644, or equal to about 22 per cent. of the share capital. I have received letters from two or three shareholders in reference to the report. It is very remarkable that out of our large constituency—scattered all over the country—I have not received more. They are all complimentary, but one of them asks me to give some special answer as to the reserve fund. Now, gentlemen, the policy that we are pursuing as far as possible is to make your property a sound and permanent investment [applause]. You cannot have, as the saying is, a dividend and your property increasing in value at the same time. I mean to say that by a large reserve fund you place your property in a strong position. You are getting a moderate but a satisfactory dividend I hope, and at the same time your property is increasing in value I may say every six months. We wish to maintain the Company in that position, because, as I shall have occasion to tell you by and by, there are threatened oppositions. These oppositions we shall require to meet, and I think you will all agree that we shall fight better, if it is necessary to do so, if we have a substantial amount in our exchequer. I may also mention that many of our cables have been laid for a very considerable period. We do not wish to add to our capital. We wish to maintain our system by making renewals as far as we can out of income; and, if we can only maintain our cables in an efficient way out of income, depend upon it it is better for the interests of all concerned. We are quite in ignorance of what the "life" of a cable may be. Some have extended the limit to twenty and thirty years, and it is even said a more remote period than that is possible; but this we do know, that in our system we have had to renew lately a cable which was down for only twelve years. That shows the uncertainty of this class of property, and until we know more about it, I think it is better for the shareholders and all concerned that we should go on increasing our reserve fund.

A Shareholder: Can you tell us where that cable was?

The Chairman: Yes, between Singapore and Batavia. Against the revenue for the past half-year, the following sums have been charged for strengthening and improving the Company's system, namely:—Balance of cost of Singapore-Saigon and Penang-Rangoon cable renewals, £2,692. Then there was the cost of duplicating the Victoria-Tasmania cable, £31,190, and the cost of a small connection, &c., in China, £2,193, making a total of £36,076, which we have practically expended in the strengthening of our system. It has also been found necessary, in consequence of the frequent interruptions of late years, involving costly repairs, to replace the Singapore-Penang (old) section with a new brass-ribboned cable. On a previous occasion I showed you that in the amounts we were paying for repairs there would be a very considerable saving by our putting down a new cable rather than go on with that annual expense. We have had to fight the teredo. You see we have to fight both at the bottom of the sea as well as on the surface; but I think we have shown that so far we have mastered the teredo. The new brass-ribboned cable, to replace this Singapore-Penang section, will leave in the Telegraph Construction Company's ss. "Seine" in a few days. By this means it is hoped that a considerable saving will be effected under Abstract "C." A large proportion of the old line will probably be picked up, and after it has been overhauled and put into good order will be taken into the company's stock of spare cable at Singapore. The cable steamer "Recorder," built to replace the ill-fated ss. "Magneta," has safely arrived at her station at Singapore, and has relieved the ss. "Agnes," which is now on her way home for repairs. The "Recorder" encountered exceptionally severe weather when passing through the Bay of Biscay, but sustained very little damage. Her cost has been written off against the maintenance ships' reserve fund, as shown in the published accounts. You see that we are not adding to our own capital; but we are adding immensely to the power and efficiency of our property as a whole [applause]. I will now touch upon a question which I daresay you are all, more or less, interested in—I refer to the negotiations which have been going on for some time in the Australian colonies in regard to a reduction of tariffs. It will be seen from the report that the Company have decided to make substantial reductions in the rates both to Australia and China, to take effect from the 1st July next, when the Berlin Convention comes into force. We had to fight a hard battle at Berlin in the interest of the companies, and I hope that it has not been fought without success. Our object has been to meet our promises to the full extent; at the same time, while satisfying the public, to protect the interests of our shareholders [applause]. For Australia we are going to reduce the rate from 10s. 8d. to 9s. 4d. a word, and for China we are going to reduce the rate from 8s. 4d. to 7s. 1d. We had hoped that the negotiations with the Indian Government would have resulted in the lowering of their high transit rate, so that the larger reduction for Australia of 2s. per word as proposed at Berlin might have been brought about. Unfortunately, however, our efforts in this direction were not successful, and consequently we had to negotiate with the Australian colonies on a fresh basis, as it was out of the question for the Company to bear the whole of the heavy loss which the 2s. reduction would have involved, without some assistance from India or the colonies. Since these remarks were written we have received a letter from the Indian Government opening, I hope, negotiations again with a view to a better arrangement of traffic across India, and at lower rates. If those negotiations should terminate successfully it will lead to a further reduction to our Australian colonies. The decision to reduce by 1s. 4d. was arrived at after considerable negotiation with the Agents-General of the Colonies. In fact, the suggestion came from one of the Agents-General, and we are always prepared to act upon any suggestion that we consider practical and beneficial to both parties concerned. We agreed to the 1s. 4d. reduction unconditionally, and to reduce the rate by a further 1s. 4d. provided all the colonies would join in the subsidy which we now enjoy of £32,400 a year and extend for a further six and a quarter years. The subsidy has about fourteen years to run, and we proposed that if they extended it, and made it twenty years from the present time, we would make this further reduction of 1s. 4d., making in all 2s. 8d. This would give the Company time to recoup the loss that might be sustained from the reduction in the event of the reduced tariff not recouping us to the extent necessary. I may mention that most of the present subscribing colonies were prepared to agree to this arrangement—that is New South Wales, South Australia, and Western Australia; but Victoria is still in doubt. We are, however, hopeful that the arrangement may eventually be carried out; and if so, it will be very largely beneficial to the telegraphing public, and I think will place the Company in a very secure position as against any loss from the reduction. I am about to give you the figures which will show that it was only reasonable to ask for some such assistance from the colonies. We have been blamed for not giving them the whole reduction without any reference to our income or means to do so. It is very well for people to ask for this benefit; but there are always two to a bargain, and I hope we shall always be able to show that any bargain we may make we shall be able to justify, and that it is made not only in the interests of the telegraphing public, but in the interests of the shareholders. The estimated loss by the reduction of 1s. 4d. for Australia is £20,000, and by the reduction of 1s. 3d. for China £22,000, being together £42,000. That is what we have to meet at the present time. The further 1s. 4d. for Australia, if the Company's proposal is accepted, would represent an additional £20,000. In other words, we should have to face a loss of £62,000; but we should have as against that the £32,400 a year for six years. As I have said, our proposal was recommended by the Agents-General more or less warmly. Others wished to consult the Governments they represented before expressing their views. But on the whole it was well received by the Agents-General in London. Queensland and New Zealand, however, have refused to entertain it on the ground that the rate ought, in their opinion, to be only a fraction of the present charge, and that they were not prepared to take any action that would tend to discourage the establishment of an opposition cable. Queensland, apparently, has never forgiven us for connecting our system with the South Australian lines instead of joining on to their system, and notwithstanding the many attempts we have made to conciliate her she still evinces uncompromising hostility towards us. Only recently we offered, at our own expense, to connect her system with the South Australian lines by laying a cable from the Roper River to Normanton, at a cost of something like £70,000. This would provide the colonies with an alternative land line which they have long desired, and give Queensland direct communication with Europe; but the offer was refused, Queensland contending that she ought to have an independent cable of her own. The unreasonableness of this contention is obvious

Digitized by Google

when it is remembered that the existing cables are equal to many times the present traffic, and that Queensland's proportion is only 5½ per cent. of the whole traffic with Australia. Still Queensland desires to dictate and control the other colonies. My impression is that these colonies which have supported us, and support us so well, will refuse to be influenced by parties who appear to be largely influenced by sentiment in this matter. The proportions of the traffic are as follows:—Victoria, 30¾ per cent.; New South Wales, 32½ per cent; South Australia, 15¼ per cent.; New Zealand, 13¾ per cent.; Queensland, 5½ per cent.; Western Australia, 1 per cent.; and Tasmania, 1 per cent. Nevertheless, judging from statements that have appeared in the newspapers, it would seem that efforts are being made by persons who wish the public to believe that they are officially representing the Colonial Governments in this matter for establishing a second cable to Australia. The routes advocated are:—First, from Queensland to Ceylon, touching at Java or Timor, a length of about 4,500 knots, costing about £787,000. This, though the cheapest, is not the scheme most in favour. The second route is from Western Australia to England *viâ* the Mauritius, South Africa, and the West Coast, a length of about 14,600 knots, costing over £2,500,000. The third route is from Brisbane to San Francisco or Vancouver's Island, touching at Honolulu, Feejee, and New Caledonia, a length of about 8,000 knots, costing, say, £1,500,000. The latter seems to be preferred; but both the Mauritius and Pacific routes present exceptional difficulties in the way of enormous depths, long stretches of cable, and eventual costly repairs, while the financial aspect, under the most favourable circumstances, does not promise a sufficient return to cover working expenses, and amortization at a 5s. tariff, unless the colonies are prepared to largely subsidise the project. It is, perhaps, not quite understood that the Extension Company established their line to Australia without any subsidy whatever from our own Government, or from any of the Australian Colonies. When, however, telegraphy is once established it assumes such an important position both in politics and commerce that its continuity becomes a necessity, therefore no one line can be relied on, and consequently the policy of the Companies which I have the honour to represent has been to render telegraphy a certainty by the general duplication of the system. I think it is right to add that the leading colonies in Australia felt the necessity of continuous communication as much as we did. Frequent interruptions of our line brought this prominently to the front, and I think all honour is due to the colonies of Victoria, New South Wales, South Australia, and Western Australia, for enabling the company to provide a second communication by giving the subsidy of £32,400 per annum for 20 years. The enterprise and spirit shewn by these Colonies were never shared by Queensland, and only for a short time by New Zealand, during which she contributed to the subsidy and then withdrew. It is to me remarkable that these Governments did not see the advantage of joining with the others in accepting the Company's proposals for reducing the tariff to 8s. by sharing in the subsidy and extending it for 6½ years, as the saving by the reduction would more than counter-balance their contributions to the subsidy, namely, the saving to Queensland by the reduction would be about £4,000 per annum against a contribution of £3,100. To New Zealand a saving of £10,600, against a contribution of £5,700. Consequently they would be better off by £900 and £4,500 respectively if they joined in the company's scheme. Now, I say it is unreasonable for them to refuse to join in such an arrangement. The idea is that if they come into this combination they would build up a great monopoly, and by establishing another cable they would create competition that must eventually benefit the colonies. I have had some experience in competition in submarine cables, and I can tell you that they are probably, of all things, a system which ought, more or less, to be exempted from competition. The present cables can carry a great deal more—four times as much—traffic as Australia is likely to provide for some years to come. The effect of the introduction of another company subsidised by Governments would be that neither would pay. It would be a serious loss to the colonies as regards subsidy, and a serious loss to us in our income. We have that exemplified in the case of the Atlantic cables at the present time. There is only a certain amount of telegraphy that you can rely upon every year. If a new company gets in they may obtain their proportion of the traffic, or even at first more than their proportion, as they come in under the pretence of their going to lower the rates; but the result is and always must be that the public must pay for the competition. I believe the present rates in the Atlantic are so unremunerative that the next movement must be a considerable advance, following on a very considerable reduction in the rates. In making the reductions which I have mentioned, I wish to show you that your Board are doing everything they possibly can to conciliate the different Governments of the Australian colonies. We are anxious that there should be a federation in regard to telegraphy. There is a talk of federation in regard to the colonies for great political purposes. If they quarrel with this small matter of telegraphy, I see very little hope of a grand scheme of federation being carried out. Still, I believe this, that these colonies are governed by men of great enterprise and experience, and that the small jealousies which exist at this moment, even against telegraphy, will by perseverance and conciliation be brought to an end, and that we shall eventually enjoy the confidence of the non-contributing colonies, as we do the confidence of the contributing colonies, and in that case I have no fear for the future. There is one question I would refer to to show our efforts at conciliation. Our subsidy of £7,500 per annum, payable by the Governments of New Zealand and New South Wales, in respect of the New Zealand Cable, expired the other day. We pointed out that the traffic had developed very slowly, and that after ten years' working, the traffic without the subsidy only gave an average nett return on the capital invested of 3 per cent., without putting by anything for amortization and for cost of repairs. If this had been done the return would have been insufficient to meet working expenses. The New South Wales Government agreed to renew the subsidy for a further term of ten years, on condition that the Company made certain reductions in the local tariff, but the New Zealand Government would only agree to a renewal for five years, which we did not see our way to accept unless it formed part of the larger subsidy proposal. Subsequently the New Zealand Government endeavoured to induce the New South Wales and Queensland Governments to join them in laying an opposition cable between Sydney and New Zealand, but their efforts have not so far met with any success. We had contemplated at the time the subsidy ceased raising the tariff to make up the loss of subsidy, but as this would have caused inconvenience to the telegraphing public of both colonies, we have intimated that the Company will not make any alteration in the rates before the 1st July next, by which time we hope some satisfactory solution will be arrived at. Speaking of opposition schemes to Australia, which probably are intended to benefit the promoters quite as much as the colonies, and about which considerable animus has been shown by some of those who have been disappointed—a short time ago, during my absence abroad, when the approval of a concession by the Government for a cable to the West Coast of Africa came before the House of Commons, a concession which had occupied quite two years to negotiate, and which negotiations were in the hands of the Liberal, then the Conservative, and again the Liberal Government, and probably no bargain was ever more carefully considered in the interest of a Government than this particular concession—nevertheless, the Government and myself were taxed with dishonesty in the transaction. Both the Liberal and Conservative members of the Governments, however, so completely answered the insinuations that it leaves me nothing to say about the impotent and abortive attack, excepting this—that one of the speakers let the cat out of the bag when he said that if the concession were approved, then a proposal which he had in view for connecting Australia by the West Coast of Africa could not be adopted. He made a personal attack simply because he found that the House was going to accept a fair, moderate, and reasonable concession. He saw it was going to blast his hopes of the work he had in view. This particular concession is the one to which I have just referred, viz., 14,600 knots. Our negotiations with the Colonial Governments are still progressing, and I am not without hope that they will lead to the full reduction of 2s. 8d. per word to Australia. At the last meeting I referred to the probability of a rate of 2s. 8d. per word being introduced for Press messages exchanged with Australia. Unfortunately difficulties have since arisen to delay its introduction, one being that the Indian Government made their consent conditional on the application of the reduced tariff to all the Australasian colonies instead of to the four colonies who contribute to the Company's subsidy of £32,400 per annum. This question has, however, been referred to the Governments of the contributing colonies, and we are now awaiting their decision. Now, gentlemen, I think I have given you a very large amount of information. You know pretty well what is going on at the present time. But I would just before I conclude say that it is our object, if we possibly can, to come to such an arrangement with the Australian colonies as will give them a very considerable reduction. At the same time it must be based on the principle that will protect the interests of the shareholders. I think I have shown you that what we are doing is practically in the interests of those who are most opposing us. With these remarks I beg to move the following resolution:—"That the report and accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 2s. per share, both free of income tax, payable on the 15th inst., making, with the previous distributions, a total payment of 7 per cent. for the year 1885."

The Right Hon. Viscount MONCK: I beg to second the motion.

The CHAIRMAN: If any gentleman has any questions to ask I shall be glad to answer them before I put the resolution.

Mr. SURTEES: Will you be kind enough to reply to one question? This is the first half-year that I have been a shareholder of this Company, and I do not follow as well as the older shareholders the form of your abstract "D"—the account of the reserve fund. I notice that the amount expended is £537,000. I do not know whether those investments have been valued at the price of the present day, or whether it means that that is what those investments have cost, or whether it means that they have been purchased without reference to the amount that is now proposed to be carried to the fund, namely, £39,000 odd? The amounts here do not tally.

The CHAIRMAN: The figures of the investments show what is invested. The difference between the two amounts is more or less floating. You will find, for instance, traffic and other debit balances £105,657, loans on deposit £80,000, cash at the bank £36,000, and so on.

Mr. SURTEES: I did not know whether the values are those of the present day.

The CHAIRMAN: What we give in the first column is the value of the stock, and in the other column is what we paid for it. We find, taking a balance occasionally, that we are considerably on the right side.

Mr. JOHN NEWTON: May I ask why you did not print in your report the drawn numbers of the bonds that are to be paid off? I think that shareholders will find after six months have elapsed that their bonds are drawn off six months before, and they lose six months' interest. That is unsatisfactory. If you put it into the report it has also the advantage of showing to the shareholders, those who had not the bonds as well as those who had, that you are reducing the debentures.

The CHAIRMAN: I do not think there can be any real reason for not putting it into the report. We have still a spare sheet left, and may as well occupy it. It is our desire to give the shareholders every possible information. We shall take notice of the point.

Mr. NEWTON: May I ask whether the reserve fund, which is so substantial, will be available for fighting purposes in the remote

Digitized by Google

future, because I do not think competition is likely to come upon us for many years, and probably the impending fight in the Atlantic will show the evils of such competition. I should like to ask you whether the reserve fund is available for this purpose, so that if you have to fight at a future time the shareholders' interests during the struggle will not suffer. Can you utilise your reserve fund not only for renewals, but for securing the shareholders' dividend during the period of struggle?

The CHAIRMAN: I think I made a remark in the course of my few observations that we could fight all the better for having a good round sum in the exchequer.

Mr. NEWTON: Yes, that prompted my remark.

The CHAIRMAN: It is not a question to decide now. When the time comes to fight, if it ever does, we shall use our reserve fund in the best way to defend the Company's interests.

A SHAREHOLDER: It is the Company's standing army.

Mr. HEIRON: With respect to the possibility of having to meet competition, may I ask if steps have been taken to establish a new company for that purpose?

The CHAIRMAN: From my observation, and from all I can learn, I think there is no fear of a company being formed to oppose us at the present moment. I do not believe the colonies will give any subsidy for the purpose. They will be very much better off to use the money in reducing our tariffs, than in subsidising a competing line. There are, however, men at work now, and as long as there are men who think they can turn a penny you will find them at work—they have been at work to my knowledge for a great many years—but as far as I can learn there is no immediate prospect of any money being got to lay down cables to Australia and China.

Mr. HEIRON: That is a very satisfactory answer.

The CHAIRMAN: We are watching every movement, and are always on the alert.

Mr. HEIRON: It is said that a company has been formed already.

The CHAIRMAN: I am sorry to say that you cannot believe all that you read in print.

Mr. CUFF: You have paid for your new vessel out of the ships' maintenance fund. When do you expect to be paid for the lost vessel? And when that is done will the fund stand at something like the amount it was before we purchased this last new ship?

The CHAIRMAN: We have received the money from the insurance people, and we have spent that money on the new ship.

Mr. CUFF: In addition?

The CHAIRMAN: We had never taken anything out for the "Magneta." We should have done so if the "Magneta" had not been lost, but we got the insurance for that vessel, and that left the account pretty much as it is at the present time. He then put the motion, which was carried unanimously. Continuing, he said the next resolution is—"That the Right Hon. Viscount Monck, who now retires by rotation, be and is hereby re-elected a Director of this Company."

The Marquis of TWEEDDALE seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed, "That Sir William M'Arthur, K.C.M.G., who now retires by rotation, be and is hereby re-elected a Director of this Company."

Sir JAMES ANDERSON seconded the motion, which was carried unanimously.

On the motion of Mr. WM. FORD, seconded by Mr. FULLER, the following resolution was carried unanimously:—"That Mr. Henry Dever and Messrs. Quilter, Ball, and Co. be re-elected auditors for the ensuing year at a remuneration of £100 each."

The CHAIRMAN having intimated that that closed the business,

Mr. HEIRON said: Before we separate we have one duty to perform—that is to give a vote of thanks to the Chairman and the Board for the very able and efficient manner in which they have conducted the business during the past half-year. I think a more able or a more efficient statement could scarcely have emanated from the Chairman than that which we have heard to-day. I take it that this is one of the most gigantic companies in existence—it is a very extensive Company—and as long as we have a Board who so thoroughly understand this business, and we are so ably and efficiently represented, the shareholders may rest perfectly confident that their interests will be taken care of. It is not only a question of the ability of the Directors, but they require to be gentlemen of high commercial and social standing and reputation, because they come in contact with various Governments, and the power which they exercise, owing to their influential position, is used for our advantage. I move that our thanks be accorded to the Chairman and Directors.

Mr. SURTEES seconded the motion, which was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I beg to return you our best thanks. I have gone perhaps more into details to-day than I should under ordinary circumstances. My reasons for doing so are that I think when there are rumours floating about regarding opposition it satisfies shareholders to have as much information as the Board can possibly give. I think the greater the confidence that exists between the Directors and the shareholders, the more able are we to carry on successfully the important duties of this Company. You have said very truly that this system extends over every part of the civilised world, and our work is not confined to Board meetings only. It is almost every half hour in the day that we are called upon to take some steps to protect your interests or develop your trade. Consequently it is no light position, but a very onerous one, to carry on, and to carry on successfully, a large submarine system such as that which is represented by the gentlemen on this side of the table. I hope we shall continue to enjoy your confidence; we shall certainly do our best to secure it.

The proceedings then terminated.

Oriental Telephone Company.

Report of the Directors for the year ended 31st December last, to be presented at the sixth ordinary general meeting of the Company, at the Cannon-street Hotel, on Tuesday, 20th inst., at 1 p.m.:—

The profit and loss account for the year exhibits a credit balance of £3,569. 17s. 6d., which shows a slight improvement on the returns of the previous year, in spite of irregularities on the part of the late manager at Mauritius, a loss on the working of the Colombo branch, together with the further heavy fall in the Eastern exchanges. The improvement is in some measure due to reductions in the London expenses. The Indian guarantees are still a very heavy burden on the resources of the Company, but full provision has been made for last year's claims in respect thereof in the item of £4,436. 3s. 5d. Although the expansion of the Indian revenues has been very slow, and some withdrawals of Exchange subscribers have taken place, owing to financial failures and the general depression of trade, on the whole the results from India are better than last year. The local companies in Bombay and Calcutta are now introducing the "Magneto" system throughout their "exchanges," and it is hoped that with a more efficient service thus provided, a considerable increase in the number of subscribers at each place will follow. From Bombay latterly the advices have been much more encouraging. Your Directors have thought it advisable to revalue the stores on hand at the various agencies, and the result is that an amount of £480. 16s. 11d. has been written off, chiefly on the value of instruments which had been sent out in the earlier days of the Company, and which have been found to be unsuitable. A sum also of £305. 7s. 11d. has been charged in respect of the Egyptian indemnity, the £1,000 reserved on this account having proved insufficient to meet the expenses in connection therewith. After writing off all the above items, the balance remaining to the credit of profit and loss is £2,292. 10s. 4d., which it is proposed to carry forward. It has been found necessary to make several alterations in regard to the management in the East, and the result has been beneficial. The question of the rights of the Company in Australasia has occupied a considerable time in the deliberations of the Board, and will continue to engage their serious attention. Your Directors are glad to be able to report an increase in the revenues of the subsidiary companies—notably in that of the Egyptian Company — the shares of which are almost entirely held by your Company. The Egyptian Company has earned and paid during the past year 5 per cent. on the issued Preferred Capital. Your Directors would point out that these shares, although of the nominal value of £5 each, are only credited in the balance-sheet at a value of less than £2. 10s. per share. In China the business has been placed on a better footing, and your Directors have accepted from the China and Japan Company £4,200 7 per cent. mortgage debentures in settlement of the balance due by that company, whose position now shows a distinct improvement. The present Board, feeling that the Articles of Association, especially as altered from the original form, place undue power in the hands of the Directors, have carefully considered the matter, and propose certain alterations giving greater influence to the votes of the shareholders, and these proposed alterations will be submitted at an extraordinary general meeting. You will be asked to authorise the payment of the expense incurred by the Committee of Investigation, amounting to £72, and whether the said committee shall receive an award for their services. The Directors retiring are Messrs. Henry Grewing and Thomas Lloyd, who offer themselves for re-election. Messrs. Deloitte, Dever, Griffiths, and Co., the auditors of the Company, retire, but offer themselves for re-election.

SUBMARINE CABLES TRUST.

NOTICE IS HEREBY GIVEN that the COUPONS of the Submarine Cables Trust due on 15th inst. will be PAID on and after that date by Messrs. Glyn, Mills and Co., of 67, Lombard-street, between the hours of Ten a.m. and Two p.m.

The Coupon must be left for examination three clear days previous to calling for pyment.

LEWIS WELLS,
Secretary.

50, Old Broad-street, E.C., April 9, 1886.

THE EASTERN EXTENSION AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).

5% AUSTRALIAN GOVERNMENT SUBSIDY DEBENTURES.

NOTICE IS HEREBY GIVEN that in pursuance of the conditions upon which the above Issue was made, the under-mentioned numbers of Debentures were drawn by lot on the 12th April, at the Offices of the Company, Winchester House, 50, Old Broad-street, in the City of London, in the presence of SIR JAMES ANDERSON, the SECRETARY, and of JOHN VENN, Esq., Notary Public.

The said Debentures will be paid off at par on 1st day of July next, at Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C., after which date interest on them will cease

251 Debentures of £100 each.

"THE ELECTRICIAN."—WANTED, Vols. I. to X.—State price to M. P., Office of this Paper.

JOURNAL OF THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

Edited by F. H WEBB, Secretary.

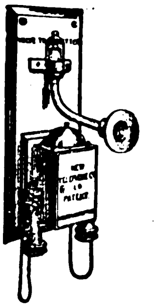
No. 60, containing the INAUGURAL ADDRESS of the PRESIDENT, PROFESSOR D. E. HUGHES, F.R.S., consisting of an ACCOUNT of his RESEARCHES on the SELF-INDUCTION of an ELECTRIC CURRENT in relation to the NATURE and FORM of its CONDUCTOR; with important discussion thereon, including remarks by Lord Rayleigh, Mr. Frank Pope, Prof. G. Forbes, Dr. J. Hopkinson, Mr. Preece, Dr. Fleming, Mr. D. FitzGerald, Prof. S. P. Thompson, Prof. Ayrton, and the PRESIDENT'S REPLY, with ACCOUNT of FURTHER RESEARCHES. Together with Abstracts from various Scientific Periodicals, English and Foreign.

Price Four Shillings.

E. and F. N. SPON, 125, Strand, W.C.

NEW TELEPHONE CO., LIMITED

(Under License from the Postmaster-General).



The above Company is SELLING TELEPHONES to the Public outright. These Telephones are Manufactured under the Patents of Professor Silvanus P. Thompson and others, and are now in successful operation in leading towns in the kingdom.

The Company will give a formal guarantee to any purchaser requiring the same against any claims which may be made by trade rivals for alleged infringements.

This Company is now receiving applications for the establishment of local exchanges.

PRICE £16 PER PAIR.

For full particulars apply to the Secretary,

NEW TELEPHONE COMPANY, LTD.

4, Great Winchester Street, London, E.C.

NALDER BROS.,

Instrument Makers, Electricians, and General Electrical and Mechanical Engineers,

Office: 8, Victoria Chambers, WESTMINSTER, S.W.

Steam Factory, Brent Electric Works, The Ham, Brentford.
Laboratory, The Butts, Brentford.

Manufacturers of Resistance Boxes, Wheatstone Bridges, Thomson and other Galvanometers, Lampstands and Scales, Electrometers, Cóndensers, Keys, and Electrical Standards of every description.

VOLTMETERS and CURRENT INDICATORS.

Cathetometers, Micrometers, Bar Callipers, and all descriptions of Electrical, Physical, and Mathematical Instruments. Experimental work undertaken. Chloride of Silver and other Batteries. Switch Boards, Switches, and Electric Light Fittings.

Instrument Cabinet Work.

Complete Installations of Electric Light undertaken. Engines, Dynamos, Motors and Lamps supplied.

PARKINSON & FRODSHAM'S

NON-MAGNETIZABLE WATCH.

Will stand the test of Long Exposure to the most powerful Dynamo.

With Seconds Dial for Counting the Speed of Dynamos. In Silver Cases. Keyless Lever. Jewelled in Six Holes. Cannot be overwound.

Guaranteed for 3 Years. Price £2 10s.

4, CHANGE ALLEY, LONDON, E.C.

INSTRUCTIONS FOR THE LAYING AND JOINTING OF UNDERGROUND ELECTRIC CABLES. Profusely Illustrated. Translated from the French of Dr. FRANCOIS BOREL. Post free.

NOTES.

URUQUAY.—The land lines in Uruguay are now restored.

PERSIAN GULF.—The cable between Fao and Bushire is interrupted.

PARA.—The cable between Maranham and Para is again in working order.

ELECTRIC LIGHTING IN AMERICA.—We learn from an American contemporary that the electric light is to be established at Jackson, Tenn.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th inst. amounted to £2,964.

BELGIUM.—On the 26th inst. the members of the Belgian Society of Electricians will visit the Electro-Technical Institute at the University of Liége.

THEORY OF THE TELPHONE.—M. M. E. Mercadier has contributed a very interesting article on this subject in a current number of the *Journal de Physique.*

THE THOMSON-HOUSTON ELECTRIC LIGHTING COMPANY.—We understand that the contract to light Selma, Ala., has been received by the above firm.

FRENCH ATLANTIC CABLE.—According to *The Times* New York correspondent, April 19th, a fault has occurred in this cable some 220 miles from Duxbury.

ELECTRIC LIGHTING IN COPPER MINES.—Twenty-five 2,000 candle power Weston electric arc lamps have been erected in the Osceola mill, and were lighted for the first time on the 30th March.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 15th April are £3,327, as compared with £4,033 in the corresponding period of 1885.

EXPORTS.—The value of telegraphic wire and apparatus exported during the first three months of this year was less by £51,971 than in the corresponding period of last year, the respective values being £124,074 and £176,045.

ELECTRIC LIGHTING AT THE LEEDS TOWN HALL.—The lighting of this hall is in course of preparation. The lamps have been placed in position, and we understand that one or two preliminary trials of their illuminating power have been made.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th inst. were £2,466, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CLECKHEATON.—Application has been made by the National Telephone Company for permission to erect telephone poles, the company intending to open a telephone exchange in the town. The permission for these poles was granted at the last meeting of the local board.

THE ELECTRIC LIGHTING ACTS.—The Society of Arts has presented a petition against the No. 3 Electric Lighting Act Amendment Bill (the Government Bill) and in favour of No. 1 Amendment Bill (Lord Raleigh's). The Lords' Committee will commence their inquiry on 13th May.

MADRID.—Spanish advices state that a project is under the consideration of the Provincial authorities of Madrid, for an important extension of the telegraph and telephone system, which, if carried into effect, will give that province a more complete system of official telegraphic communication than in any other part of Spain.

SALES OF PLANT.—Messrs. Wheatley Kirk, Price, and Goulty announce the sale, at an early date, of a large quantity of electrical plant, including the entire manufacturing plant, electrical apparatus, instruments, &c., of the Consolidated Electric Company (in liquidation). Further particulars will be found in our advertisement columns.

JOURNAL OF THE SOCIETY OF TELEGRAPH-ENGINEERS.—The part of the *Transactions* just issued is perhaps one of the most valuable that has ever been printed by the society, containing as it does the inaugural address of Prof. Hughes and the full discussion thereon. The paper and the critical remarks deserve long and careful study from every student.

FIRE AT LIVERPOOL TELEGRAPH EXCHANGE.—We understand that the breakdown caused by the late fire was remedied within five days, and the exchange is again in working order. Twenty miles length of wire were destroyed and eighteen hundred wires had to be cut away. Great credit is due to Mr. W. A. Sharp, the electrician, and Mr. Rowe, the engineer, for their energy in so rapidly repairing the damage.

VAPOUR FROM SECONDARY BATTERIES.—Mr. F. Higgins, in the *Transactions* of the Society of Telegraph-Engineers, suggests the use of a loose cover, such as the thinnest calico, to arrest the minute globules of acid projected into the air from secondary batteries. By this means the work in the vicinity of accumulators which are being charged is much less unpleasant, and the corrosion of metal work prevented.

APPLICATION OF ELECTRICITY TO ORGANS.—*La Lumière Electrique* states that a new organ in the Church of Nizior at Lyons is actuated by means of electro-pneumatic transmission. The system adopted is that of MM. Schmœle and Mols, of Philadelphia, and simplifies very largely the parts between the keys and the chest. The organ is really in different parts, and electricity offers the best mode of actuating the instrument.

THE WESTINGHOUSE COMPANY.—If the electric light does not develop in England by "leaps and bounds," the reason why is not far to seek. These reasons are almost absent in the States; hence we see how much more rapidly the light "goes." The Westinghouse Company have introduced modified Siemens machines and incandescent lamps. The standard lamp of 16 candle-power is guaranteed to have a life of 600 hours, with seven lamps to the indicated horse-power.

TELEGRAPHING FROM MOVING TRAINS.—Mr. L. J. Phelps, from New York, has obtained a patent for telegraphing from trains. His method is not quite the same as Edison's, the latter telegraphing from the roof of the car to wires upon folds parallel with the line, while Mr. Phelps proposes to lay a wire between the two rails and to telegraph from the bottom of the car. No doubt there is a distinction, but we fail to see that whether the apparatus is upon the roof or below the floor gives claim to a new patent.

ANTI-TRAMP PROTECTOR.—A recently-married electrician, says the *Electrical World,* who lives near Sacramento, Cal., has devised a scheme for protecting his wife from the annoyance of tramps. The vagrants invariably sought the kitchen *viâ* a rear stairway, so the electrician detached the four bottom steps from the others, and attached a powerful battery to them. A wire from the battery runs into the kitchen, and when a tramp is seen approaching all that is necessary is to touch a spring at the proper moment, and the astonished seeker after provender is thrown nearly over the back fence.

SPANISH TELEPHONE STATISTICS.—The Spanish telephone system, according to statistics just issued by the Director-General of Posts and Telegraphs, consisted on the 30th June

Digitized by Google

last of a central station and five branches in Madrid, 517 private stations, opened by virtue of the law of 1882, and 62 private stations established in accordance with the law of 1884. The expenses of the telephone service in the first half of 1885 are returned at 280,000 pesetas, say £11,200, and the revenue £1,162 only; but it is pointed out that the materials and installations cost £7,420, the cost of erection £422, and accessories £734.

MADEIRA.—*The Monthly Correspondent* issued from this charming island contains some notes by a Hindoo, relative to his education in England, as well as other information, among which we notice that preparatory to the opening of the new African cables, two practice rooms have been opened at the Madeira Station for the learners who will be engaged at the stations. Four underground lines have been laid between the two rooms. In the rooms are Morse's ink-writers, sounders, and mirrors already fitted. Two clock-work siphon recorders are to be set up. Thus the two rooms are fair models of actual stations.

PATENTS.—Mr. Lack, the Comptroller of the Patent Office, and Mr. J. H. G. Bergne, the Superintendent of the Treaty Department of the Foreign Office, have been appointed by the President of the Board of Trade to represent this country at the third meeting of the International Conference for the Protection of Industrial Property, which is to be held at Rome at the end of this month. Mr. Lack and Mr. Bergne will be accompanied by the Master Cutler of Sheffield and Mr. Herbert Hughes, the secretary to the Sheffield Chamber of Commerce, who, from their technical knowledge, will be able to render them valuable assistance as experts.

LANCASHIRE AND CHESHIRE TELEPHONE EXCHANGE COMPANY.—This company has 1,993 miles of trunk wires, single circuit, in operation, connecting some thirty of the principal towns in the district. The public appreciation of the intertown telephone facilities provided by this company will be best judged from the fact that more than 1,500 (nearly 50 per cent) of its subscribers make regular use of the trunk wire system. The company has nearly completed the erection of Trunk wires to join up with those of the National Telephone Company's Yorkshire system. The wire used for the purpose of trunk line communication is the same as the company is gradually introducing in their local exchange system, namely, 16s hardened copper.

PORTSMOUTH.—Mr. Sandy, the local manager of the Western Counties and South Wales Telephone Company, has been explaining to the popular ear how we speak three thousand miles away. It may be hypercritical of us to say that we do not speak three thousand, although we can communicate over that distance. In his lecture, Mr. Sandy stated that the longest distance he had ever spoken was about 110 miles, from London to Norwich, and this was accomplished with perfect success. The experiments were shown to the audience, and communications were carried on between Portsmouth and Southampton. All lectures of this kind are valuable in that they are educating the public to appreciate the wonderful applications science has given to them.

GREENOCK.—A correspondent writes to the *Glasgow Herald* with regard to defective telegraphic communication at Greenock, as follows:—"Would you be kind enough to give publicity in your valuable paper to the fact that at Greenock the telegraph office is closed from 10 p.m. till 7 a.m. Greenock was thus unable within the last 10 days to receive until 7 a.m. of the following day two messages addressed, 'Steel, Greenock,' handed in at Moville at 9:45 p.m. and 11 p.m., thus preventing the steam tenders for the mails and passengers of ss. 'Circassia' and ss. 'Ethiopia' getting the necessary intimations of the times these steamers would reach the tail of the bank. The messages giving notice were despatched from Moville, but were received at Glasgow and *posted* to Greenock."

BLUE PRINTING BY ELECTRIC LIGHT.—The Western Edison Light Company of Chicago, after some experimenting, have adopted an arrangement for taking blue print by electric light, as being always ready when sun light is wanting. The apparatus consists of three hand regulating arc lamps, with carbon five-eighths of an inch diameter. The three arcs are connected in series, and the current is supplied from the incandescent dynamo which lights the company's premises. The electromotive force is 115 volts, and the current used is about 40 amperes. An iron wire resistance of 4 ohms is connected with the lamps, and thrown in when starting the current, being cut out after the light is started. A good print can be taken in 2½ to 10 minutes, a longer exposure being required for larger prints, which cannot be placed so near the light as the smaller ones.

SPANISH TELEGRAPH STATISTICS.—The official telegraph statistics of Spain for the first half of 1885 have just been published. They show that in that period fifteen new telegraph stations were opened to the public, of which seven belong to the State and eight to the railway companies, only one station having been closed. The increase of wire in the six months was 108 kilometres, bringing up the total on the 30th June last to 17,596 kilometres of line, 129 of subterranean cable, and 236 of submarine cable. The number of stations belonging to the State was 534, those of the railway companies open to the public 330, semaphoric six, municipal 16, and private one. The messages transmitted numbered 1,608,091, of which 1,245,326 were internal telegrams and 362,765 foreign. The internal telegrams comprised 164,883 official messages, 982,291 private, 38,188 private messages of the railway companies, and 59,876 service telegrams. The State revenue from telegrams during the six months was £101,000.

EXECUTION BY ELECTRICITY.—Senator McMillan, of Buffalo, U.S., has introduced in the Legislature a Bill which provides for the appointment of a commission to investigate and report the most humane method of inflicting capital punishment. The Bill is probably the result mainly of the efforts of Dr. A. P. Southwick, of Buffalo. "Dr. Southwick proposes to execute criminals by means of electricity, by which death would be instantaneous. The method which he proposes is very simple. His idea is to use an ordinary chair. In this city a wire could be run from the electric light works to the gaol. The man would sit in the chair with his head resting against its back. The wire entering an insulated substance, such as rubber or glass, would constitute the positive pole By placing the man's feet upon a metallic plate a connection would be formed with the poles. At a signal a switch in another room could be turned. The current would enter at the base of the brain, the centre of the nervous system, and pass through the man. The heart would stop beating, and a complete paralysis would ensue."

OVERHEAD WIRES.—Mr. E. Cracknell, superintendent of telegraphs for New South Wales, has proposed a plan to prevent injury from the breaking of overhead wires. He proposes to remove the wires from mid air, and to enclose them in a case resembling a frieze, to be placed close to the buildings. The frieze will be supported by pillars sunk in the ground 4ft. 6in., and 14ft. 6in. in height. Connecting these pillars are cast-iron beams 18in. wide, called friezes, and behind them are

Digitized by Google

to be placed eight racks for holding cables, which are clusters of fifty wires embedded in an insulating substance, and coated with cement. They make a cable of 1in. in diameter. It is estimated that the rack will hold 400 wires easily. On reaching the street crossings the racks will be made to descend to the level of the road, and be carried underground to the other side, where they will rise to the previous level. A trial section of this new line is about to be erected at a probable outlay of £5,000. One objection to this plan will be urged by companies that the length of wire required in each case will be twice the length of the pillars multiplied by the number of crossings. We are almost inclined to think that an underground system would in the long run be almost as cheap as that above described.

Lighthouse Illuminants.—Mr. J. R. Wigham, in a lecture on this subject at Monkstown, stated with regard to electricity that the electric arc light was the one with which most people were familiar in this connection. In England the lighthouse stations of the South Foreland, Souter Point, and the Lizard had the electric light as their illuminant; and in France there were eight lighthouse stations at which it was used. Its power in clear weather was enormously greater than that of either gas or oil. But this extreme brilliancy was misleading to the sailor, for he could not be certain of his distance from the light; for it looked equally bright whether it was five miles or only one mile off. It was not during fine weather that one required a powerful light; for such weather a light might be too bright. Any ordinary lighthouse light would show to the horizon in clear weather; but the best lighthouse illuminant was the light which could be farthest seen in foggy weather, when the mariner most required it. It was here that the electric light failed. The greatest of all the defects of the electric light, however, was its unsteadiness, and the existence of this defect had caused the French lighthouse authorities to abandon for the present their intention of further extending the use of the light on the coast of France.

The Electric Light in Mines.—"Mr. Thomas Conelly read before the Manchester Geological Society, on March 2nd, a paper on the progress of electric lighting in mines. After giving a very careful account of the experiments which have been made, Mr. Conelly drew attention to some important facts which appear to have escaped attention. Especially he referred to the question of using the electric light in fiery collieries. He admitted that well-constructed arrangements allowed of the electric light being used with 'a moderate degree of safety right up to the face of the coal,' but he stated 'it had been found that the electric spark would ignite gas, and where there was a liability to very fiery outbursts, it was within the range of possibility that a miner might cause such an injury to the electrical arrangement as might be the cause of an explosion.' This important fact cannot be too generally known, as a considerable amount of misconception exists in relation to the electric spark and its powers." Thus far from the *Athenæum*, a contemporary that at any rate is supposed to have its intelligence well up to date. If a critic is so ignorant of what is generally known, to whom shall we look for enlightenment? In all humility we ask if there is one single word in this paragraph about which "considerable misconception exists?" The facts stated therein have been discussed a thousand times, and are as familiar to electricians as the conquest of England by William I. is to historians.

Telephonic Experiments.—During the past week the Northern District Telephone Company have opened the trunk lines between Middlesborough and Stockton and Stockton and Hartlepool. These events were celebrated by telephonic "at homes" at Middlesborough on Wednesday, Stockton on Thursday, and Hartlepool on Friday. The invitations issued by Mr. Clay, the manager of the company, were much appreciated by large audiences. The Theatre Royal at Middlesborough being connected, the performances given by the Royal English Opera Company were distinctly heard, and when it is stated that every word and note of music could be heard at Hartlepool (a distance of rather over nineteen miles) just as plainly as at the company's exchange in Middlesborough, further comment upon the excellent way in which the line has been erected is unnecessary. In addition to the Opera Company the services of several gentlemen belonging to the Telephone Company were called into play, and the musical talent developed by them, each in his own peculiar way, was extraordinary, everyone apparently being gifted with a voice of some sort, and not a few being very tolerable performers upon instruments such as the violin, flute, piano, banjo, and guitar. The greatest credit is due to all connected with the erection of these trunk lines, considering the difficulties in the route, and the bad weather experienced during the past winter, and the company may be congratulated on having such energetic and able servants as Messrs. Neave, Preston, and Bailey, the managers respectively at Middlesborough, Stockton, and Hartlepool. Mr. Clay probably derives considerable satisfaction from the verdict expressed in the local papers that "the system of the Northern District Telephone Company is as near perfect as possible."

Long-Distance Telephone Lines.—"The American Telegraph and Telephone Company," says the *Electrical World*, "organised for long-distance work, is using some of the largest cables for submarine and underground use ever laid in this country. Its entire cable equipment is of Kerite. The number of crossings between New York and Philadelphia are seven, viz., North River, twice across the Kills, Raritan, Rancocas and Delaware Rivers, and in addition an underground cable across Ridgeway Park, opposite Philadelphia. The conductors in all the cables, with the exception of one series, are composed of three No. 18 B.W.G. copper wires with Kerite insulation, measuring $\frac{9}{32}$ of an inch outside diameter, the submarine cables being armoured with eighteen armour wires, each weighing 810lb. to the mile. One cable throughout the entire series has its conductors, which are seven in number, composed of three No. 16 B.W.G. copper wires stranded together, equal in weight to 210lb. of copper to the mile, and insulated with Kerite to an outside diameter of $\frac{11}{32}$ of an inch. These in turn are taped, laid up and sewed with packing to receive nineteen No. 3 B.W.G. galvanised iron armour wires, weighing 950lb. to the mile. The entire series of cables are four in number, of seven conductors each, making a total of twenty-eight conductors. Conversation over the line is perfect, and this, to a great extent, is due to the low resistance of the conductors and their perfect insulation. It is satisfactory to know that our home manufacturers are now competing successfully with those abroad as to construction and character of submarine cables, and that even better results, both electrical and mechanical, can now be obtained in this country for both submarine and underground cables." Is not this last sentence just a "little" too showy? Surely England and Germany are still ahead, so far as submarine cables are concerned.

West Australia.—West Australia is making an effort to overtake her sister colonies in the matter of telegraphic and telephonic communication. In the small place of Honolulu the Hawaiian Telephone Company has as many as 400 subscribers, which is a paying number. If in such a place as Honolulu the

Digitized by Google

telephone system has met with such success, there is little reason why in Western Australia it should not be received with equal favour. The Government are now taking active steps towards establishing telephone exchanges in Perth and Freemantle. They have secured the services of Mr. William J. Hancock, A.S.T.E., of Dublin, as Superintendent of Telephones, and that gentleman arrived in Perth about a month ago to commence his duties. Mr. Hancock has had considerable experience in the working of telephones in connection with the Dublin Exchange, which has about 900 subscribers, who used it to the extent of about 7,000 messages per diem. Since his arrival here Mr. Hancock has superintended the construction of telephone communication between Government House and the office of the Colonial Secretary. He is now making arrangements for the organising of an exchange in Perth and another in Freemantle. The plan to be adopted in each town is simply this:—A central office with switch room will be established, and from this will be run the wires to the subscribers, each subscriber being given a separate wire. The switchboard will be worked by girls, whose voices are better adapted to the purpose than those of boys. The duties of these operators will be simply to manipulate the switch-board so as to place any subscriber in communication with any other with whom he wishes to converse. Not a word of the conversation will be heard in the switch room. In course of time it is intended that a couple of trunk lines shall be run between Freemantle and Perth, so that the subscribers in the two towns may be able to converse with each other as occasion requires. It has not yet been decided what shall be the rent charged to subscribers, but should there be a fair number of them—say a hundred—in each town, it will probably be fixed at the low sum of £16. The telephone that will most likely be employed is the Bell and Blake instrument, which is clear speaking and rarely gets out of order. The Gower-Bell, which is chiefly used in England, is loud speaking but not very distinct. It is not expected that the exchange in either town will be established within six months; but we may mention that apparatus and material have been ordered from England.

UNDERGROUND WIRES.—"The second report of the Brooklyn Commissioners of Electrical Subways," says the *Electrical World*, "is not only an interesting document, but a valuable one, and does great credit to the intelligence and prudence of its authors. The commissioners have wisely determined to leave the work in the hands of the companies interested, and to gather experience from the results obtained by them. This is not only wise, but just, as it affords the electrical companies no ground for complaint at any subsequent failure. The Board seems to hold a favourable opinion of the creosoted wood conduit which has been in use some months in Brooklyn, but, in accordance with its plans of experiment and tolerance, has permitted the laying of Dorsett and Richardson conduits. The intelligent examination of the cables laid in the creosoted wood conduit has already brought out a fact which may prove of the greatest value in the manufacture of lead-cased cables, and which will no doubt be acted upon. Under the course which the Board is pursuing, a comparison will soon be possible of the relative advantages of air-tight and water-tight conduits and those in which the joints are not tight, and this question is becoming more and more important with the substitution of the destructive water-gas for coal-gas. Through the labours of this Board a large number of wires have already been put underground, and the end of the summer will find many of Brooklyn's most encumbered streets comparatively clear, giving Brooklyn the largest underground mileage of wire of any city in the country. In view of such real and valuable services rendered, it is hardly right that thus far the commissioners have received no compensation—a fact due to the loose manner in which the Bill creating the Board was framed. The lack of funds also prevents the employment of a competent inspector, and inspection work thus far has been done by the Board itself. This obstacle to a faithful performance of duty should be removed at once, either by the companies' action in the matter according to the provisions of the Bill, or by the State itself. Brooklyn is to be congratulated upon its advance in this matter, and we would strongly recommend the report to the attention of the New York Commission, which at present is unfortunately delayed in its action by the illness of one of its members. It is to be regretted that the report contains nothing in relation to electric light wires, but confines itself to telephone and telegraph lines. However, we are promised something about that for the future, and so must wait."

WAR OF CABLE RATES.—The Anglo-American Telegraph Company, the Direct United States Company, and the Western Union Company have forwarded us circulars to the effect that on and after the 5th May next the charge for the transmission of telegrams between the United Kingdom, France, Germany, and all the principal telegraph stations in the United States of America and Canada will be sixpence per word. Special arrangement can be made at the general offices of the company for the transmission of press messages at 3d. per word. These cable companies have our entire sympathy, for it is hard to the management and to the shareholders that after they have proved the possibilities of Atlantic telegraphy, made the first experiments from experience, introduced the necessary changes in apparatus and cables—we say it is hard that a new company should come in and lay cables that are not wanted, there not being sufficient traffic for those already laid, and try to reap some advantage by their action. It seems to us that nowadays pioneers in any direction are not appreciated; the sole aim appears to be to get rid of the pioneers, and for some one else to reap the benefit of their labours. We sincerely trust that those Americans who have dabbled in late editions of Atlantic cables will find that their fingers have been well burned for their pains. The Central News says: On Friday last an important conference was held at the offices of the Anglo-American Cable Company for the purpose of considering the advisability of commencing "a war of rates" against the Commercial Cable (Mackay-Bennett) Company. The conference lasted two hours, and the companies constituting the "pool" —namely, the Anglo-American, Western Union, Direct United States, and the French Cable Company—were fully represented; the delegates present including Mr. John Pender, Mr. von Chauvin, Mr. Fuller, M. Pouyer-Quertier, M. Riant, Mr. Underdown, Viscount Monck, Mr. F. Weaver, &c. After considerable discussion it was resolved that, as the Commercial Company persisted in their refusal to join the "pool," or to agree to an increase in the present cable rates to America, the pool companies on and from the 5th of May should reduce their charges for private despatches to sixpence per word, and for press messages to threepence per word. The drastic character of the new tariff may be gathered from the fact that the rates in operation at present are 1s. 8d. for private despatches and 10d. for press messages. The new rates will apply not only to the United Kingdom, but to messages despatched from France, Germany, &c., and the charges will include the cost of transmission to most of the American and Canadian commercial centres, for which it has hitherto been customary to make additional charge. Up to Tuesday last the Commercial Cable Company had made no move.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 387.)

Some Notes on Magnetisation.

The long delay in the publication of the last section has somewhat thrown me off the track. The revision and condensation of manuscript matter require a preliminary mental preparation. I therefore interpolate a section, intended to come later, previously written, for the most part, on a subject which has more than common interest at the present date (March 27), owing to recently-published experimental investigations. After this, I shall conclude the subject of the stresses in the briefest manner possible, by omission and abridgement.

Although it is generally believed that magnetism is molecular, yet it is well to bear in mind that all our knowledge of magnetism is derived from experiments on masses, not on single molecules, or molecular structures. We may break up a magnet into the smallest pieces, and find that they, too, are little magnets. Still, they are not molecular magnets, but magnets of the same nature as the original; solid bodies showing magnetic properties, or intrinsically magnetised. We are nearly as far away as ever from a molecular magnet. To conclude that molecules are magnets because dividing a magnet produces fresh magnets always would be clearly unsound reasoning. For it involves the assumption that a molecule has the same magnetic property as a mass, a large collection of molecules, having, by reason of their connection, properties not possessed by the molecules separately. (Of course, I do not define a molecule to be the smallest part of a substance that has *all* the properties of the mass.) If we got down to a mass of iron so small that it contained few molecules, and therefore certainly not possessing all the properties of a larger mass, what security have we that its magnetic property would not have begun to disappear, and that their complete separation would not leave us without any magnetic field at all surrounding them of the kind we attribute to intrinsic magnetisation. That there would be magnetic disturbances round an isolated molecule in motion through a medium, and with its parts in relative motion, it is difficult not to believe in view of the partial co-ordination of radiation and electro-magnetism made by Maxwell. But it might be quite different from the magnetic field of a so-called magnetic molecule—that is, the field of any small magnet. This evident magnetisation might be essentially conditioned by structure. not of single molecules, but of a collection, together with relative motions connected with the structure, this structure and relative motions conditioning that peculiar state of the medium in which they are immersed, which, when existent, implies intrinsic magnetisation of the collection of molecules, or the little mass. However this be, two things are deserving of constant remembrance. First, that the molecular theory of magnetism is a speculation which it is desirable to keep well separated from theoretical embodiments of known facts, apart from hypothesis. And next, that as the act of exposing a solid to magnetising influence is, it is scarcely to be doubted, always accompanied by a changed structure, we should take into account and endeavour to utilise in theoretical reasoning on magnetism which is meant to contain the least amount of hypothesis, the elastic properties of the body, speaking generally, and without knowing the exact connection between them and the magnetic property.

Hooke's law, *Ut tensio, sic vis*, or strain is proportional to stress, implies perfect elasticity, and is the first approximative law on which to found the theory of elasticity. But beyond that, we have imperfect elasticity, elastic fatigue, imperfect restitution, permanent set.

When we expose an unmagnetised body to the action of a magnetic field of unit inductivity, it either draws in the lines of induction, in which case it is a paramagnetic, is positively magnetised inductively, and its inductivity is greater than unity; or it wards off induction, in which case it is a diamagnetic, is negatively magnetised inductively, and its inductivity is less than unity; or, lastly, it may not alter the field at all, when it is not magnetised, and its inductivity is unity.

Regarding, as I do, the force and the induction—not the force and the induced magnetisation—as the most significant quantities, it is clear that the language in which we describe these effects is somewhat imperfect, and decidedly misleading in so prominently directing attention to the induced magnetisation, especially in the case of no induced magnetisation, when the body is still subject to the magnetic influence, and is as much the seat of magnetic stress and energy as the surrounding medium. We may, by coining a new word provisionally, put the matter thus. All bodies known, as well as the so-called vacuum, can be inductised. According to whether the inductisation (which is the same as "the induction," in fact) is greater or less than in vacuum (the universal magnetic medium) for the same magnetic force (the other factor of the magnetic energy product), we have positive or negative induced magnetisation.

To the universal medium, which is the primary seat of the magnetic energy, we attribute properties implying the absence of dissipation of energy, or, on the elastic solid theory, perfect elasticity. (Dissipation in space is scarcely within a measureable distance of measurement.) But that the ether, resembling an elastic solid in some of its properties, is one is not material here. Inductisation in it is of the elastic or quasi-elastic character, and there can be no intrinsic magnetisation. Nor, evidently, can there be intrinsic magnetisation in gases, by reason of their mobility, nor in liquids, except of the most transient description. But when we come to solids the case is different.

If we admit that the act of inductisation produces a structural change in a body (this includes the case of no induced magnetisation), and if, on removal of the inducing force, the structural change disappears, the body behaves like ether, so far, or has no inductive retentiveness. Here we see the advantage of speaking of inductive rather than of magnetic retentiveness. But if, by reason of imperfect elasticity, a portion of the changed structure remains, the body has inductive retentiveness, and has become an intrinsic magnet. As for the precise nature of the magnetic structure, that is an independent question. If we can do without assuming any particular structure, as for instance, the Weber structure, which is nothing more than an alignment of the axes of molecules, a structure which I believe to be, if true at all, only a part of the magnetic structure, so much the better. It is the danger of a too special hypothesis, that as, from its definiteness, we can follow up its consequences, if the latter are partially verified experimentally, we seem to prove its truth (as if there could be no other explanation), and so rest on the solid ground of Nature. The next thing is to predict unobserved or unobservable phenomena whose only reason may be the hypothesis itself, one out of many which, within limits, could explain the same phenomena, though, beyond those limits, of widely diverging natures.

The retentiveness may be of the most unstable nature, as in soft iron, a knock being sufficient to greatly upset the intrinsic magnetisation existing on first removing the magnetising force, and completely alter its distribution in the iron; or of a more or less permanent character, as in steel. But, whether the body be para- or dia-magnetic, or neutral, the residual or intrinsic magnetisation, if there be any, must be always of the same character as the inducing force. That is, any solid, if it have retentiveness, is made into a magnet, magnetised parallel to the inducing force, like iron.

Until lately only the magnetic metals were known to show retentiveness. Though we should theoretically expect retentiveness in all solids, the extraordinary feebleness of diamagnetic phenomena might be expected to be sufficient to prevent its observation. But, first, Dr. Tumlirz has shown that quartz is inductively retentive, and next, Dr. Lodge (*Nature*, March 25th, 1886) has published some results of his experiments on

Digitized by Google

the retentiveness of a great many other substances, following up an observation of his assistant, Mr. Davies.

The mathematical statement of the connections between intrinsic magnetisation and the state of the magnetic field is just the same whether the magnet be iron or copper, para- or dia-magnetic, or is neutral. In fact, it would equally serve for a water or a gas magnet, were they possible. That is,

$$\text{curl.}\,(\mathrm{H}-h)=4\pi\Gamma\,; \qquad \text{div.}\,\mathrm{B}=0\,;$$

H being the magnetic force according to the equation $B=\mu H$, where B is the induction and μ the inductivity, Γ the electric current, if any, and h the magnetic force of the intrinsic magnetisation, or the impressed magnetic force, as I have usually called it in previous sections where it has occurred, because it enters into all equations as an impressed force, distinct from the force of the field, whose rotation measures the electric current. It is h and μ that are the two data concerned in intrinsic magnetisation and its field; the quantity I, the intensity of intrinsic magnetisation, only gives the product, viz., $I=\mu h/4\pi$. It would not be without some advantage to make h and μ the objects of attention instead of I and μ, as it simplifies ideas as well as the formulæ. The induced magnetisation, an extremely artificial and rather unnecessary quantity, is $(\mu-1)\,(\mathrm{H}-h)\,4\pi$.

It will be understood that this system, when united with the corresponding electric equations, so as to completely determine transient states, requires h to be *given*, whether constant or variable with the time. The act of transition of elastic induction into intrinsic magnetisation, when a body is exposed to a strong field, cannot be traced in any way by our equations. It is not formulated, and it would naturally be a matter of considerable difficulty to do it.

In a similar manner, we may expect all solid dielectrics to be capable of being intrinsically electrised by electric force, as described in a previous section. I do not know, however, whether any dielectric has been found whose dielectric capacity is less than that of vacuum, or whether such a body is, in the nature of things, possible.

As everyone knows nowadays, the old-fashioned rigid magnet is a myth. Only one datum was required, the intensity of magnetisation I, assuming μ to be unity in as well as outside the magnet. It is a great pity, regarded from the point of view of mathematical theory, which is rendered far more difficult, that the inductivity of intrinsic magnets is not unity. But we must take Nature as we find her, and although Prof. Bottomley has lately experimented on some very unmagnetisable iron, which may approximate to $\mu=1$, yet it is perfectly easy to show that the inductivity of steel magnets in general is not 1, but a large number, though much less than the inductivity of soft iron, and we may use a hard steel bar, whether magnetised intrinsically or not, as the core of an electromagnet with nearly the same effects, as regards induced magnetisation, except as regards amount, as if it were of soft iron.

Regarding the measure of inductivity, especially in soft iron, this is really not an easy matter, when we pass beyond the feeble forces of telegraphy. For all practical purposes μ is a constant when the magnetic force is small, and Poisson's assumption of a linear relation between the induced magnetisation and the magnetic force is abundantly verified. It is almost mathematically true. But go to larger forces, and suppose for simplicity we have a closed solenoid with a soft iron core, and we magnetise it. Let F be the magnetic force of the current. Then, if the induction were completely elastic, we should have the induction $B=\mu F$. But in reality we have $B=\mu(F+h)=\mu H$. If we assume the former of these equations, that is, take the magnetic force of the current as *the* magnetic force, we shall obtain too large an estimate of the inductivity, in reckoning which H should be taken as the magnetic force. This may be several times as large as F. For, the softer the iron the more imperfect is its inductive elasticity, and the more easily is intrinsic magnetisation made by large forces; although the retentiveness may be of a very infirm nature, yet whilst the force F is on, there is h on also. This overestimate of the inductivity may be partially corrected by separately measuring h, after the original magnetising force has been removed, by then destroying h. But this h may be considerably less than the former. For one reason, when we take off F by stopping the coil current, the molecular agitation of the heat of the induced currents in the core, although they are in such a direction as to keep up the induced magnetisation whilst they last, is sufficient to partially destroy the intrinsic magnetisation, owing to the infirm retentiveness. We should take off F by small instalments, or slowly and continuously, if we want h to be left.

Another quantity of some importance is the ratio of the increment in the elastic induction to the increment in the magnetic force of the current. This ratio is the same as μ when the magnetic force is small, but is, of course, quite different when it is large.

As regards another connected matter, the possible existence of magnetic friction, I have been examining the matter experimentally. Although the results are not yet quite decisive, yet there does appear to be something of the kind in steel. That is, during the act of inductively magnetising steel by weak magnetic force, there is a reaction on the magnetising current very closely resembling that arising from eddy currents in the steel, but produced under circumstances which would render the real eddy currents of quite insensible significance. In soft iron, on the other hand, I have failed to observe the effect. It has nothing to do with the intrinsic magnetisation, if any, of the steel. But as no hard and fast line can be drawn between one kind of iron and another, it is likely, if there be such an effect in steel, where, by the way, we should naturally most expect to find it, that it would be, in a smaller degree, also existent in soft iron. Its existence, however, will not alter the fact materially that the dissipation of energy in iron when it is being weakly magnetised is to be wholly ascribed to the electric currents induced in it.

P.S., April 13.—As the last paragraph, owing to the hypothesis involved in magnetic friction, may be somewhat obscure, I add this in explanation. The law, long and generally accepted, that the induced magnetisation is simply proportional to the magnetic force, when small, is of such importance in the theory of electro-magnetism, that I wished to see whether it was minutely accurate. That is, that the curve of magnetisation is, at the origin, a straight line inclined at a definite angle to the axis of abscissæ, along which magnetic force is reckoned. I employed a differential arrangement (differential telephone) admitting of being made, by proper means, of considerable sensitiveness. The law is easily verified roughly. When, however, we increase the sensitiveness, its accuracy becomes, at first sight, doubtful; and besides, differences appear between iron and steel, differences of kind, not of mere magnitude. But as the sensitiveness to disturbing influences is also increased, it is necessary to carefully study and eliminate them. The principal disturbances are due to eddy currents, and to the variation in the resistance of the experimental coil with temperature. For instance, as regards the latter, the approach of the hand to the coil may produce an effect larger than that under examination. The general result is that the law is very closely true in iron and steel, it being doubtful whether there is any effect that can be really traced to a departure from the law, when rapidly intermittent currents are employed, and that the supposed difference between iron and steel is unverified.

Of course it will be understood by scientific electricians that it is necessary, if we are to get results of scientific definiteness, to have true balances, both of resistance and of induction, and not to employ an arrangement giving neither one nor the other. He will also understand that, quite apart from the question of experimental ability, the theorist sometimes labours under great disadvantages from which the pure experimentalist is free. For whereas the latter may not be bound by theoretical requirements, and can employ himself in making discoveries, and can put down numbers, really standing for complex quantities, as representing the specific this or that, the former is hampered by his theoretical restrictions, and is employed, in the best part of his time, in the poor work of making mere verifications.

(To be continued.)

CORRESPONDENCE.

SELF-INDUCTION OF WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We read in the pages of history of a monarch who was "*super grammaticam.*" All truly great men are like that monarch. They have their own grammars, syntaxes, and dictionaries. They cannot be judged by ordinary standards, but require interpretation. Fortunately the liberty of private interpretation is conserved.

No man has his own grammar to a greater extent than Prof. Hughes. Hence, he is liable, in a most unusual degree, to be misunderstood, as I venture to think he has been by many, including Mr. W. Smith, whose interesting letter appears on p. 455, and Prof H. Weber, p. 451.

The very first step to the understanding of a writer is to find out what he means. Before that is done there cannot possibly be a clear comprehension of his utterances. One may, by taking his language in its ordinary significance, hastily conclude that he has either revolutionised the science of induction, or that he is talking nonsense. But to do this would not be fair. We must not judge by what a man says if we have good reason to know that what he means is quite different. To be quite fair, we must conscientiously endeavour to translate his language and ideas into those we are ourselves accustomed to use. Then, and then only, shall we see what is to be seen.

When Prof. Hughes speaks of the resistance of a wire, he does not *always* mean what common men, men of ohms, volts, and farads, mean by the resistance of a wire—only sometimes. He does not equally define what it is to be when the accepted meaning is departed from. But by a study of the context we may arrive at some notion of its new meaning. It is not a definite quantity, and must be varied to suit circumstances. Again, there is his "inductive capacity" of a wire. We can only find roughly what that means by putting together this, that, and the other. It, too, is not a definite quantity, but must be varied to suit circumstances. It is not the coefficient of self-induction, nor is it any quantity defining a specific quality of the wire, like conductivity, or inductivity. It is a complex quantity, depending on a great many things, but which may, to a first rough approximation, be taken to be proportional to the time constant of the wire, the quotient of its coefficient of self-induction by its resistance. Bearing these two things in mind, we shall be able to approximate to Prof. Hughes's meaning.

Owing to the mention of discoveries, apparently of the most revolutionary kind, I took great pains in translating Prof. Hughes's language into my own, trying to imagine that I had made the same experiments *in the same manner* (which could not have happened), and then asking what are their interpretations? The discoveries I looked for vanished for the most part into thin air. They became well known facts when put into common language. The satisfaction of getting verifications, however, even in so roundabout and rough a manner, is some compensation for the disappointment felt. I venture to think that Prof. Hughes does not do himself justice in thus deceiving us, however unwittingly, and that possibly there has been also some misapprehension on his part as to what the laws of self-induction are generally supposed to be.

I have failed to find any departure from the known laws of electro-magnetism. In saying this, however, I should make a reservational remark. There may be lying latent in Prof. Hughes's results dozens of discoveries, but it is impossible to get at them. For consider what the mere existence of ohms, volts, and farads means? It means that, even before they were made, the laws of induction in linear circuits were known, and very precisely. To get, then, at new discoveries requires very accurate comparison of experiment with theory, by methods which enable us to see what we are doing and measuring, in terms of the known electro-magnetic quantities. This is practically impossible, on the basis of Prof. Hughes's papers. We can only make very rough verifications. I have had myself, for many years past, occasional experience with induction balances, of an exact nature, true balances of resistance and induction, and always found them work properly. But, in the modification made by Prof. Hughes, the balance is generally of a mixed nature, neither a true resistance nor a true induction balance, and has to be set right by a foreign impressed force, viz., induction between the battery and telephone branches. By using a strictly simple harmonic E.M.F., as of a rotating coil, we may equally formulate the conditions of the false balance, and then, noting all the resistances, &c., concerned, derive, though in a complex manner, exact information. Or, if we use true balances, any kind of E.M.F. will answer.

To illustrate the falsity of Prof. Hughes's balances and the difficulty of getting at exact information he finds the comparative force of the extra currents in two similar coils in series to be 1·74 times that of a single coil. From the context it would appear that this comparative force of the extra currents is the same thing as the former inductive capacity of wires. Now, the coefficient of self-induction of two similar coils in series, not too near one another, is double that of either, whilst the time constant of the two is the same as of either. This can be easily verified by true balances.

The most interesting of the experiments are those relating to the effect of increased diameter on what Professor Hughes terms the inductive capacity of wires. My own interpretation is roughly this. That the time constant of a wire first increases with the diameter, and then later decreases rapidly; and that the decrease sets in the sooner the higher the conductivity and the higher the inductivity (or magnetic permeability) of the wires. If this be correct, it is exactly what I should have expected and predicted. In fact, I have already described the phenomenon substantially in this journal; or, rather, the phenomenon I described contains in itself the above interpretation. In *The Electrician* for January 12, 1884, I described how the current starts in a wire. It begins on its boundary and is propagated inward. Thus during the rise of the current it is less strong at the centre than at the boundary. As regards the manner of inward propogation it takes place according to the same laws as the propagation of magnetic force and current into cores from an enveloping coil, which I have described in considerable detail in this journal. The retardation depends on the conductivity, on the inductivity, and on the section, under similar boundary conditions. If the conductivity be high enough, or the inductivity or the section be large enough, to make the central current appreciably less than the boundary current during the greater part of the time of rise of the current, there will be an apparent reduction in the time constant. Go to an extreme case. Very rapid short currents, and large retardation to inward transmission. Here we have the current in layers, strong on the boundary, weak in the middle. Clearly, then, if we wish to regard the wire as a mere linear circuit, which it is not, and as we can only do to a first approximation, we should remove the central part of the wire—that is, increase its resistance, regarded as a line, or reduce its time constant. This will happen the sooner the greater the inductivity and the conductivity, as the section is continuously increased. It is only thin wires that can be treated as mere lines, and even they, if the speed be only great enough, must be treated as solid conductors. I ought to also mention that the influence of external conductors, as of the return conductor, is of importance, sometimes of very great importance, in modifying the distribution of current in the transient state. I have had for years in MS. some solutions relating to round wires, and hope some day to arrive at them in the course of the paper I am at present publishing, or rather, not publishing, as the editor has been able to afford so little space for it lately.

As a general assistance to those who go by old methods, a rising current inducing an opposite current in itself and in parallel conductors, this may be useful. Parallel currents are said to attract or repel, according as the currents are together or opposed. This is, however, mechanical force on the conductors. The distribution of current is not affected by it. But when currents are increasing or decreasing, there is an apparent attraction or repulsion between them. Oppositely going currents repel when they are decreasing, and attract

Digitized by Google

when they are increasing. Thus, send a current into a loop, one wire the return to the other, both being close together. During the rise of the current it will be denser on the sides of the wires nearest one another than on the remote sides. It is an apparent force, not between currents (on the distance action and real motion of electricity views), but between their accelerations.—Yours, &c., OLIVER HEAVISIDE.

April, 17, 1886.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret to find that I have made a slip in the working at the latter part of my article on "Ring Armatures." This I now hasten to correct.

In the expression for the polar surface for one side face of the square core, a printer's error of qd^2 for q^2a occurs. My mistake follows in the simplification, which should be

$$\frac{m\,\pi}{360}(2\,q+1)a$$

instead of

$$\frac{m\,\pi}{360}(2q\,\sqrt{a}+a)$$

This correction modifies some of the following results, viz.: —The total surface for the square core becomes

$$\frac{m\,\pi}{180}(3\,q+2)a$$

which, taking $q=\cdot 5$ afterwards works out numerically to 182·9 square inches, being 75 per cent. greater than the corresponding surface for the cylinder ring. Also the value for γ at which the two surfaces are equal, becomes

$$\gamma=\frac{3\,q+1}{q}$$

I shall feel obliged if you will insert this correction in your next issue.—Yours, &c., GUY C. FRICKER.

London, S.W., April 17th, 1886.

ELECTRIC LIGHTING BY MEANS OF LOW-RESISTANCE GLOW LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the paper on this subject read by Mr. Alexander Bernstein before the Society of Electricians, and published in your issue of the 2nd inst., the author described an ingenious switch, intended, amongst other things, to render impossible the "long-closing" of a lamp circuit in which a break of continuity should have occurred whilst "short-closed." But it would be *at least* as probable for such a break to occur in a lamp circuit when long-closed as when short-closed; and, indeed, more so, for assuming the lamps to last 1,500 hours, and working only 500 hours per annum on an average, each of these 300 lamp cut-outs must act once every three years or one every three or four days. Does Mr. Bernstein rely on the "infallability" of his cut-outs for keeping the circuit continuous? If so, I think he will find that, like a certain dignitary residing at Rome, they are only "human" after all. —Yours, &c., J. W. KEMPSTER.

Venice, 13th April, 1886.

RESISTANCE CURRENT AND E.M.F.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am just beginning to learn something of electrical science, but at the outset am very much puzzled by an inability to understand the real physical concomitants or aspects of the fundamental notions implied in the terms resistance, current, and electromotive force. The former I can see has somewhat the nature of "molecular inertia"—that is, on the assumption of electric force being manifested in the shape of molecular motion or vibration. But the only way to regard the two latter on the same hypothesis is to suppose them somewhat similar respectively to the amplitude and wave length of such a molecular vibration as that of a ray of light.

Current, for instance, seems to me to be well represented or measured by the amount or extent of motion to right or left in one plane, supposing the obverse to be in the axis of the wave motion and facing the direction in which the latter travels. Electromotive force would then be represented in direct proportion (as the last) by the distance between successive wave-tops, or by what engineers would call the "pitch."

I fear that your readers who are advanced in the subject will consider my ideas, to say the least, somewhat "loose," but I should be grateful for any hints from them as to the true way in which physically to regard an electrical vibration or current, whether it be rectilinear or in the shape of a wave, as I have assumed.

Thanking them and you in advance,—Yours, &c.,

Manchester, 19th April, 1886. STUDENT.

PARALLEL DISTRIBUTION BY TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 26th, I find a letter by Messrs. Zipernowsky, Deri and Blatly, in which they say that the system of connecting the transformers in branch circuits was patented to them. I was somewhat surprised at this statement, but on reference to their Patent Specification, No. 3,379, of 1885, I find that it is really substantiated by their second claim, which is as follows:—

"In the application of induction coils or transformers for alternating electric currents, the arrangement of several stations of second order as branch circuits of the main line, *i.e.*, connecting up the local centres with the main line in multiple arc, to which main line is supplied an alternating electric current of a tension as constant as possible, substantially as described and shown in Fig. 4."

Now, for several years past, electricians and manufacturers have used electrical apparatus connected in branch circuits for industrial purposes, such as dynamo machines, telegraphic and physical apparatus for electrolytical and metallurgical purposes, arc lamps, incandescent lamps, &c., and it would be interesting to know whether in the face of this fact, the use of parallel branch circuits for exciting transformers can form the subject of a patent according to English law.

Any information on this subject by your readers will greatly oblige.—Yours, &c., MERCURIUS.

Cologne, Germany, April 19th, 1866.

PRIMARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We beg you will allow us to give the following public reply to Mr. Verity's letter of last week, which may possibly interest other readers.

We have repeatedly used primary batteries for both temporary and permanent installations during the last three years. For the former they are very handy up to, say, 60–80 lamps of 10–12 candle-power each, as they do not need a dynamo to recharge them, and the solution is easily obtained.

We have before us a list of the installations erected to run permanently, and the following are examples. For obvious reasons we give no addresses, but may mention that we shall be pleased to give them to any one desirous of verifying our statements:—

No. 1. Installation of 50 lights, consisting of 10 candle-power and 16 candle-power incandescent and one arc lamp running since October, and lately increased to 80 lights.

No. 2. Bank in London; 34 lights, been in operation for eighteen months.

No. 3. Residence at Blackheath; 23-25 lights, including billiard table lamps, using 54 cells, lighting all lamps at one time; been in operation eighteen months. Commenced with 16 cells and 15 lights.

No. 4. Mr. M———, Atherstone, used all last hunting season 28–30 lights; running now six months.

Digitized by Google

Sussex-villas, W. ; 22 lights and 16 cells been working eighteen months.

Sir F. ———— ; 20–25 lights, for three to four months, 16 cells.

Mr. W. ————, Lee; 12–16 candle-power lamps for the last twelve months.

Experimenting with this battery a short time ago an arc lamp taking 12 amperes ran 17½ hours perfectly, the carbons then being consumed. Last month we ran 25 Swan lamps for temporary installation for three evenings of 5-6 hours each, with one usual charging; 38 cells were used, and lamps were 8-10 candle-power.

After adopting these batteries, the invention of Mr. G. C. V. Holmes, for such extended use, we are still of opinion that they afford the happiest solution for lighting small detached residences, and trust you may find a corner for this.—Yours, &c., LAING, WHARTON, AND DOWN.

8 and 9, Holborn-viaduct, London, E.C., April 21st.

N.B.—A number of trials of these batteries for special purposes have lately taken place, the complete success of which leads us to believe that a vast field for their employment is about to open, in which they will stand without a rival.

HYPNOTIC EFFECT OF THE ELECTRICAL CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would be very interesting if any of your readers would publish in your Correspondence columns their experience in the use of electricity to cure sleeplessness. The details, viz., E.M.F. and kind of cell used, the means of making contact and the direction of current, ought to be fully given.—Yours, &c.,

Clapham, April 17, 1886. F. W.

RESISTANCE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Has it ever been noticed that by altering the three coils in the "A" arm (n = R A/B) to legal units, the bridge measures resistances in L. U without further change? The fact is, of course, obvious when pointed out; but I do not think it has been, and it saves a good deal of trouble.—Yours, &c.

C. W. S. C.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to my letter published in your number of the 9th current, I have some further facts on this subject which call for attention. MM. Cailletet and Bouty described before the Paris Academy of Sciences "numerous experiments made with mercury, silver, tin, aluminium, magnesium, copper, iron, and platina, proving that the electrical resistance of these metals decreases regularly when the temperature is lowered from 0° to – 123° C., and that the coefficient of variation is apparently much the same for all." They further stated that "it seems probable that the resistance would become extremely slight at temperatures lower than 200°, but they had not carried their experiments so far." The action of the freezing mixture of – 123°C. on a copper wire would be twofold: — *First*, the normal amount of latent heat within the wire would be greatly reduced. *Second*, the molecules of the copper would be drawn closer together. Notwithstanding that the molecules of the copper would be drawn closer together, and thereby leave less space between or around them for the passage of the electricity, yet the resistance to the passage of the electricity through the wire was diminished by the removal of part of the latent heat that was within the copper. This proves that heat is in some way the obstructing element which prevents the free passage of electricity through metals.

There is another important phenomenon bearing on this subject. In the *Scientific American* of the 27th ult. there is a letter to the editor from a Mr. Charles L. Chapin, giving an account of certain engineering operations he was shown in Bermondsey when he was in this country in January, 1874. All persons acquainted with engineering know how much time and labour are required in the operation of fixing on the face plate of a large turning lathe the pieces of metal which are either to be turned or bored. A Mr. Werdermann formed the idea and patented the plan of fixing these pieces of metal by means of powerful electro-magnets. These large magnets were arranged on the face-plate of the turning lathe, so that when a piece of metal to be turned or bored was placed in its proper position on the face plate, the electricity was then switched on to the electro-magnets, and they advanced and held the piece of metal firmly without any other fastenings, thereby saving much time and labour. Owing to this invention a discovery was made of a phenomenon which Mr. Chapin says has remained unexplained until now, and he has given the information to the editor of the *Scientific American* in hopes that an explanation will be found. Every scientist knows that Count Rumford's attention was first directed to the study of heat by the very great amount of it which is produced at the boring of a hole through a mass of metal. In the engineering shop in Bermondsey Mr. Chapin saw masses of iron bored and turned, during which processes neither the bored and turned iron, nor the chips from them, showed signs of heat, and the tools used in doing the work of turning and boring were so cool that they did not require to have a stream of water kept running on them, as is commonly necessary when this work is done by the common kind of turning lathes. At the end of Mr. Chapin's letter he writes: "Mr. Werdermann's solution of the matter was simply—It was supposed that the heat of the cutting-tools was absorbed by the magnetised condition of the iron which formed the keeper of the heads of the magnets." Mr. Chapin adds in his letter: "Was this the true solution?" I reply, it is so far true; but it does not explain why these iron electro-magnets should absorb an amount of heat which could not be absorbed by much larger masses of unelectrified iron. The reason why that large amount of heat disappeared was on account of the attraction which electricity has for heat. The currents of electricity passing through the wires of the electromagnets absorbed all the free heat which came within their reach from the metal when the boring and turning was taking place, and kept the tools cool in consequence. This discovery of the late Mr. Werdermann places beyond all doubt the fact of the great attraction which electricity has for heat.

Whether electricity and heat be or be not each of them a kind of imponderable matter, it is manifest from the facts narrated in this and my previous letter, that electricity and heat are each distinct and separate elements, which cannot be transformed into one another, as has been previously supposed to be the case, in accordance with the theory of energy, as at present promulgated.—Yours, &c. JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, 10th April, 1886.

THE POLARITY OF TADPOLES.—The following, says the *Centrablatt für Elektrotechnik*, is reported about an interesting experiment of the physiologist, Prof. L. Herman. In a flat bowl filled with water, in which a number of 14-days' old frog-larvæ (of *rana temporaria*) were disporting themselves, were sunk along the narrow side ready for an experiment thick zinc wires connected with a battery of 20 little zinc carbon elements. When the current was made the whole of the little animals fell into a wriggling motion, which soon ceased. But all the larvæ without exception had taken up one position, in which the head was turned to the anode and the tail to the cathode. The animals remained in this position till the current was again broken, when they again fell into the wriggling motion, but now less violently. Repeated experiments proved that the living animals showed a decided polarity, placing themselves along the stream lines of a current with their heads all in one direction, this direction being reversed when the commutator was reversed—that is, the current was reversed. An explanation of this interesting phenomenon has not hitherto been given.

CITY AND GUILDS OF LONDON INSTITUTE.

The Report of the Governors of this important Institute for the year ending December, 1885, has just been issued, and is, on the whole, highly satisfactory. So far as it relates to the metropolis, the document is chiefly interesting from the evidence it affords of the unabated enthusiasm of the promoters, and the undiminished liberality of the patrons. Of the latter, the paragraph which we published a fortnight ago detailing the additional sums of money voted for the purposes of this Institute by the CITY GUILDS is a striking proof, not merely of the munificence of these ancient associations, but of their just appreciation of the duties devolving upon them in modern times. Judged by their deeds in England, Mr. HEALY'S Irish description of them as "Skinners and Salters" sounds like a grotesque libel. In answer to a recent appeal the various Companies interested in the Technical Education of British artisans have just increased their annual subscription by nearly £5,000, and their special grants are on an equally magnificent scale.

Handsome as are the endowments for this and its affiliated institutes in London and the provinces, they by no means exceed the requirements. The original outlay has been very great, and the cost of maintaining these establishments at a high standard of efficiency is necessarily very heavy. So far from begrudging the expense, we rejoice that it has been incurred, for it is the best security that the work will be carried out on the lines originally laid down, and on a scale commensurate with the objects to be achieved. A year ago we had to regret that the advantages of the undertaking were not being recognised by those whom it was intended to benefit as rapidly as we could wish; but there were signs of steady improvement even then, and last year's report shows that this improvement is going on at an accelerated rate. It will take some time to convince the working classes of this country, both masters and men, that their surest prospect of successfully competing with the manufacturers and artificers of foreign countries is to beat them in scientific knowledge and technical skill. Indications are not wanting that this lesson is being surely, if slowly, mastered; and we may confidently anticipate that the extensive provisions already made for supplying existing deficiencies in these respects will not long be in excess of the demand.

The CENTRAL INSTITUTION in London is now nearly completed. A good beginning has already been made in the higher branches of applied science, and in July next it is intended to start a more extended course of Technical Instruction there for Teachers, to whom lectures will be given, with laboratory instruction on special branches of technology. Prof. W. E. AYRTON, F.R.S., has been appointed to this institution as head of the electrical engineering branch, his place at the FINSBURY TECHNICAL COLLEGE having been taken by Prof. SILVANUS P. THOMPSON, late of University College, Bristol. Nearly £80,000 has been spent on the building of the CENTRAL INSTITUTE, a further sum of nearly £18,000 being expended on its fittings and apparatus. It is estimated that not less than £10,000 will be required, in addition to the students' fees, to meet the annual charges. Every year's increase, however, in the number of students will tend not to increase the required subsidy, but rather to diminish it. At present their contributions cover but a small proportion of the expenses.

Large as is the cost of this establishment, it is, we are reminded, not nearly so great as that of similar technical colleges of France and Germany. The new buildings of the ECOLE CENTRALE at Paris, designed with a like object to these in London, have now been completed at a cost of £260,000; and on the new Polytechnic school in the capital of the German Empire a sum of £340,000 has been expended. These vast establishments have been partly aided from private and public sources like our own, but largely also by the State, which in this country has contributed nothing. We differ in this respect from most of the Continental nations, a fact which indicates how much more they realise the value of higher technical instruction as an aid to national prosperity than do the statesmen of the British Empire. Speaking of the British Empire, we are glad to notice that an application has been received, which will no doubt be favourably considered, from the Board of Technical Education, NEW SOUTH WALES, for the extension of the Institute's examination to that colony. A federation of this kind will at least form one more link in the friendly bonds which unite the mother country to her children in far-off lands.

It must be borne in mind also when the expenses of these Central Institutions are in question that not nearly all the money is spent upon themselves. In the metropolis alone their grants to University College and King's College, for furthering the objects of the undertaking, amount to £800 a year; and to the Horological Institute, and the School of Art Wood Carving, further sums of £350 and £250 respectively were granted last year. Turning to the provinces, the Sheffield Firth College receives £300 per annum for five years, and Manchester and Nottingham have received £200 and £300 respectively for the past year. The cost of the Classes and Technological Examinations amounts to £3,517, and the greater part of this is of course drawn by the provinces, where it is gratifying to note that technical instruction is spreading rapidly in every direction. Much, if not the greater part, of this instruction is probably given in after-work hours. We infer this from the success of the evening classes at the London Finsbury College, where by far the most numerous attendance is in the evening; and where the receipts from fees alone amount to a very respectable sum. At this, as at similar institutes in the country, the study of elec-

Digitized by Google

trical science holds a very high position. Next to cotton manufacture in special districts, and mechanical engineering and carpentry generally, electrical engineering attracts the greatest number of candidates for examination. In this subject, as in nearly all the rest, the proportion of failures last year was less than formerly, showing that the character of the instruction is improving with the increasing facilities afforded for the training of competent teachers.

Altogether the City Guilds have reason to be proud of the work they have set on foot, and have good ground for hope that their efforts will in due time be amply rewarded in a widespread elevation of the standard of workmanship in British industrial pursuits. Their case is so good, their objects being so definite and so distinct from anything else in the field, that they have only to advocate it on its merits to ensure a favourable response. Nothing will be gained, however, we venture to remind the Governors, by exaggeration, or by setting their scheme in opposition to or rivalry of other systems of education which have a totally different aim. One of the speeches at the presentation of prizes last December seems to call for this warning. A certain Right Honourable informed the audience, with much oratorical embellishment, that for his part he was prepared to say that anyone who receives the good education that this Institute will give has got as gentlemanlike an education as he would get in archaic subjects, in Latin and Greek, and, what is more, he has got an infinitely more useful education. This eloquent personage had satisfied himself, or, at least, said he had, that what is called the liberal education of a gentleman is only "the study of antiquated ideas," which are past and done with. Those who applauded these words will see, we hope, on reflection, that a Technical Institute will not be benefited by half-truths or whole falsehoods such as these. Lord CHESTERFIELD told his son that he must learn Latin and Greek because they were the accomplishments of a gentleman; he did not say that a gentleman may not study technicology. If we do not like the gentility associated with Latin and Greek we had better say nothing about gentility, and stick to technicality. But perhaps after all the speaker we have referred to was only a chance comer, who, having nothing better to say, thought to flatter an assemblage of working men by telling them how gentlemanly they were in comparison with himself.

AN ABSOLUTE ELECTROMETER WITH CONTINUOUS INDICATIONS.*

The author says:—"We have constructed an electrometer, founded on the attraction of two concentric cylinders, and allowing the measurement of potentials in absolute value. This electrometer has the double advantage of being very easily constructed, and of giving continuous indications.

"An insulated cylinder, A A, is joined to the source whose potential it is desired to measure. A cylinder, B, whose axis is coincident with that of the first cylinder, is suspended by means of a stalk, I, to the plate P of a balance, and communicates with the earth by means of the beam of the balance. This cylinder is partly plunged in a cylindrical vessel, C, of rather larger diameter, and communicating likewise with the earth. A screen, E E E, communicating with the earth, allows the stalk I to pass through an opening; it serves to protect the balance against the attractions of the cylinder A A."

The cylinder B is pushed upward with a force which may be compared with that of gravity by putting weights on the scale-pan P and restoring it to its original position.

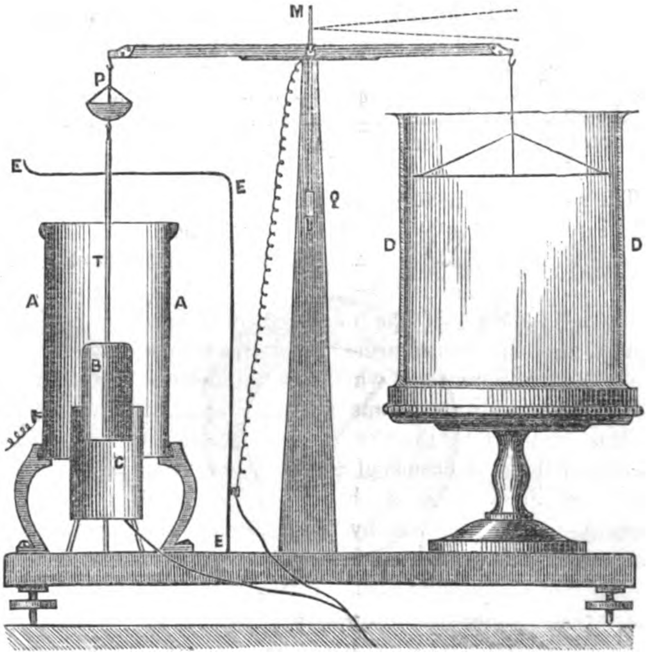
"To deaden the oscillations of the beam in the place of the second scale-pan is suspended a large cardboard disc which can rise and fall in a cylindric glass vessel, DD, of rather large diameter. The friction of the air renders the apparatus nearly dead beat."

To obtain the difference of potential V between B and A we have the formula

$$V^2 = 4\ F \log \frac{R}{r}$$

where F is the force pushing the cylinder B upwards (of course this is the weight in the scale pan $\div g$), and R and r are the respective radii of the cylinders A and B. The theory whence this formula is obtained may be found in Clerk Maxwell's large work, Vol. I., Art. 126. The theory of the quadrant electrometer is a modification of the same thing.

"The force F being between extended limits, independent of the position of the cylinder B, it follows that the instrument may also be used without employing weights and by simply observing the inclination of the beam. A mirror, M, fixed above the knife edge, allows this inclination to be measured by the method of reflection. When equilibrium is obtained, F is equal to a constant multiplied by the tangent of the angle of inclination. This constant is determined once for all by placing in the pan P a known weight, when the electrometer is discharged, and observing the corresponding deviation."



Bichat and Blondlot's Absolute Electrometer.

A counterpoise, Q, movable along a needle perpendicular to the beam, permits the sensitiveness to be modified at will.

It can be shown that the force F is not materially affected by a small lateral displacement of the axis of the cylinder B.

If we take into account the action of the stalk we have

$$V^2 = 4\ F \left\{ \log. \frac{R}{r} - \log. \frac{R}{e} \right\}$$

where e is the diameter of stalk.

* Note of MM. E. Bichat and R. Blondlot, presented by M. Lippmann at the Academie des Sciences meeting of March 29th, 1886.

NEW VOLTMETER AND AMMETER FOR CONTROL IN WORKING.*

Fig. 1 (Fig. 138 *C. E.*) shows the external form of the instrument. The round box B contains a coil and the rest of the apparatus described below. This is fastened to a mahogany slab A, which in its turn is fastened to a vertical wall by the screws *a* and *b*, the upper edge being kept carefully horizontal by means of a level.

* From the "Institute of Physics and Mechanics," of Dr. M. TH. Edelmann, at Munich, in the *Centralblatt für Elektrotechnik*, No. 7, Vol. VIII.

Digitized by Google

The essential parts are shown in Fig. 2. (Fig. 134). These are—three pieces of thin sheet iron, *m*, *n*, *p* ; the coil R, which surrounds two of the pieces of sheet iron, *m* and *n*. The piece *p* is outside the coil, and curved concentrically with it. The current which flows through the coil magnetises these three pieces of iron, of which *m* and *p* are fixed, while *n* can turn round an axis. To *n* is attached a weight, *g*, to regulate its motion, and the sensitiveness of the instrument can be increased or diminished by means of a screw, *r s*, which alters the position of the centre of gravity of *g*. The position of *n* is indicated on the scale by the pointer *z* ; *e* and *f* are the binding screws to connect the coil with the battery or dynamo.

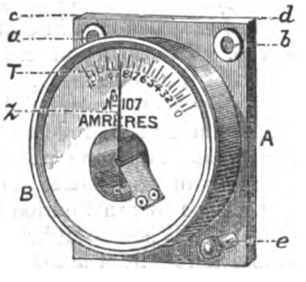


FIG. 1.

So long as the magnetising effect of the current is small, and consequently *m* and *n* close together, the repulsion between *m* and *n* is the principal force under consideration, and their magnetisation increases with the current strength. But this magnetisation will soon reach its limit, and then the attraction between *n* and the coil and between *n* and *p* will be the effect which will predominate ; *p* also acts as a shield to protect *n* from external magnetic action.

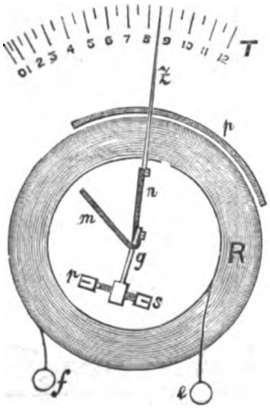

FIG. 2.

In Fig. 3 (Fig. 135) we have a curve showing the connection between current-strength and the twist of the needle. This is straight between certain limits, and it is between these limits that measurements are to be taken by the instrument.

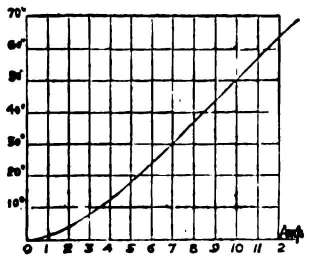

FIG. 3.

The lines of force of a coil are not in its plane, but parallel to its plane, and therefore to plane of paper. The equipotential surface which passes through the coil is in the same plane as coil—that is, it coincides with plane of paper. From the Figs. 136, &c., with their description, you would infer that the lines of force lie in the plane of the coil, and the equipotential surfaces are to parallel plane of coil and paper, which is certainly not the case. If you consider A and B as sections of the coil parallel to its plane, the lines of force are somewhat as roughly shown, and the equipotential surfaces are parallel to the force lines.

(The pieces of iron have the lines joining their poles parallel to plane of paper, not in it.)

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 440.)

Now if σ be the specific resistance of the conductor, σu equals the electromotive force parallel to the axis of x, so that

$$\sigma u = -\frac{d\phi}{dx} - A^2\frac{dU}{dt};$$

so that by the preceding equations

$$\frac{\sigma}{4\pi}\left\{\Delta^2 U - (1-k)\frac{d^2\phi}{dx\,dt}\right\} = -\frac{d\phi}{dx} - A^2\frac{dU}{dt},$$

with similar equations for V, W. The quantities U, V, W and their first differential coefficients with respect to x, y, z are continuous, and these equations enable us to find them if we know the value of ϕ, the potential of the free electricity. Helmholtz shows that the whole energy in the field due to the currents may be written

$$\frac{A^2}{8\pi}\iiint\left\{\left(\frac{dU}{dy}-\frac{dV}{dz}\right)^2+\left(\frac{dW}{dz}-\frac{dW}{dy}\right)^2+\left(\frac{dW}{dy}-\frac{dU}{dz}\right)^2 + k\left(\frac{d\phi}{dt}\right)^2\right\}dx\,dy\,dz,$$

so that if k be negative, this expression may become negative, and in that case the equilibrium would be unstable ; hence we conclude that only those theories are tenable for which k is positive.

The equations written above are those which hold in a conductor, in an insulator the equations are

$$\nabla^2 U = (1 = k)\frac{d^2\phi}{dx\,dt}$$

$$\nabla^2 V = (1-k)\frac{d^2\phi}{dy\,dt}$$

$$\nabla^2 W = (1-k)\frac{d^2\phi}{dz\,dt}$$

$$\nabla^2\phi = 0.$$

Von Helmholtz shows that in the conductor the electrostatic potential ϕ satisfies the equation

$$\nabla^2\left\{\phi + \frac{\sigma}{4\pi}\frac{d\phi}{dt}\right\} = A^2 k\frac{d^2\phi}{dt^2},$$

so that if the conductor has an infinitely small resistance, the equation becomes

$$\nabla^2\phi = A^2 k\frac{d^2\phi}{dt^2}.$$

This represents a wave motion, the velocity of propagation of which is $1/A\sqrt{k}$. If k, as in Neumann's theory, be equal to unity, then the velocity of propagation is $1/A$, and from the value of A, found from experiments on the force between circuits conveying currents, this is nearly equal to the velocity of propagation of light. Thus, according to Neumann's theory, in a perfect conductor an electrostatic disturbance is propagated with the velocity of light. In an insulator ϕ satisfies the equation

$$\nabla^2\phi = 0;$$

and this represents a motion propagated with an infinite velocity, and thus according to this theory, an electrostatic disturbance is propagated with an infinite velocity in a perfect non-conductor. In an imperfectly conducting substance the velocity of propagation of a wave notion would depend upon the length of the wave.

Let us now go on to consider, what, according to this theory, are the forces acting on an element of circuit conveying a current. Let us suppose that the element ds forms an element

Digitized by Google

of a circuit through which a current ι is flowing; then the energy of the circuit will be

$$A^2\int\iota\left\{U\frac{dx}{ds}+V\frac{dy}{ds}+W\frac{dz}{ds}\right\}ds.$$

In order to find the force parallel to x, let us suppose that each element of the circuit receives an arbitrary displacement x, parallel to the axis of x; then the alteration in the energy will be

$$A^2\int\iota\left\{\frac{dU}{dx}\frac{dx}{ds}+\frac{dV}{dx}\frac{dy}{ds}+\frac{dW}{dx}\frac{dz}{ds}\right\}\delta x\,ds+A^2\int\iota U\frac{d\,.\,\delta x}{ds}ds.$$

Integrating the second term by parts, we see that it may be written

$$[A^2\iota U\delta x]-A^2\int\iota\left\{\frac{dU}{dx}\frac{dx}{ds}+\frac{dU}{dy}\frac{dy}{ds}+\frac{dW}{dz}\frac{dz}{ds}\right\}\delta x\,ds.$$

Substituting this value for the second term, we see that the alteration in the energy,

$$=[A^2\iota U\delta x]+A^2\int\iota\left\{\frac{dy}{ds}\left(\frac{dV}{dx}-\frac{dU}{dy}\right)-\frac{dz}{ds}\left(\frac{dU}{dz}-\frac{dW}{dx}\right)\right\}\delta x\,ds;$$

hence we see, by the Conservation of Energy, that there is a force on each element of current parallel to the axis of x equal to

$$\iota\left\{\frac{dy}{ds}\left(\frac{dV}{dx}-\frac{dU}{dy}\right)-\frac{dz}{ds}\left(\frac{dU}{dz}-\frac{dW}{dx}\right)\right\}A^2,$$

and by symmetry forces parallel to y and z equal respectively to

$$\iota\left\{\frac{dz}{ds}\left(\frac{dW}{dy}-\frac{dV}{dz}\right)-\frac{dx}{ds}\left(\frac{dV}{dx}-\frac{dU}{dy}\right)\right\}A^2;$$

$$\iota\left\{\frac{dx}{ds}\left(\frac{dU}{dz}-\frac{dW}{dx}\right)-\frac{dy}{ds}\left(\frac{dW}{dy}-\frac{dV}{dz}\right)\right\}A^2,$$

so that the resultant of these forces is at right angles to the element. In addition to these forces there are other forces at places where the quantity ιU is discontinuous, or, since U is continuous, at places where ι is discontinuous, whose components parallel to the axes of x, y, z, are respectively

$$A^2 U\,\delta\iota,\qquad A^2 V\,\delta\iota,\qquad A^2 W\,\delta\iota;$$

but $\delta\iota$ equals de/dt, the rate at which the free electricity is increasing at the place, so that we have at any place where the free electricity is changing a force whose components are

$$A^2 U\frac{de}{dt},$$

$$A^2V\frac{de}{dt},$$

$$A^2W\frac{de}{dt}.$$

We saw before that the force acting on the circuit per unit length is at right angles at each point to the element of circuit at that point, so that, unless a circuit includes places at which the quantity of free electricity is changing, the circuit will behave as if it were acted on by forces which were everywhere normal to the elements on which they act. In the experiments which have been made to test whether the force on the element is at right angles to it, there have been no points where the free electricity is changing, so that these experiments do not contradict Neumann's theory, although, according to it, the force on an isolated element is not necessarily at right angles to that element, for in addition to the forces normal to the element we have forces equal to $A^2U de/dt$, $A^2V de/dt$, $A^2W de/dt$ parallel to x, y, z respectively, acting at the ends, the resultant of these two forces is a force whose components parallel to the axes of x, y, z are respectively

$$\frac{A^2\,de\,dU\,ds}{dt\,ds}$$

$$\frac{A^2\,de\,dV\,ds}{dt\,ds},$$

$$\frac{A^2\,de\,dW\,ds}{dt\,ds},$$

and as these forces are not necessarily at right angles to the element, the resultant force is not necessarily so; the effect of these forces could not, however, be detected unless there was a discontinuity in the current.

V. Helmholtz in the memoir,* which we have already quoted, shows that, according to his extension of F. E. Neumann's theory, the forces between two elements of circuit ds and ds' may be looked upon as made up of—

(1) A repulsive force on ds due to an end of de', equal (per unit length) to

$$-A^2\iota\frac{de'}{dt}\frac{1}{r}\frac{dr}{ds};$$

(2) A repulsive force on ds due to ds', equal per unit length to

$$-\frac{A^2\iota'}{r^2}\left\{2\cos(ds\,ds')-3\cos(r\,ds)\cos(r\,ds')\right\};$$

(3) A repulsion between the ends of ds and ds', equal to

$$-\frac{1}{2}(1+k)A^2\frac{de}{dt}\frac{de'}{dt};$$

(4) A repulsion on ds', due to an end of ds equal per unit length to

$$-A^2\iota'\frac{de}{dt}\frac{1}{r}\frac{dr}{ds}.$$

The second of these is the only one considered in Ampère's theory. We must remember in calculating these forces that each element has two ends.

Let us now go on to find the couples acting at each point of the circuit. If the tangent to the circuit makes an angle of θ with the axis of z, and the plane containing the tangent and the axis of z an angle ϕ with the plane xz, then we may write

$$\frac{dx}{ds}=\sin\theta\cos\phi,$$

$$\frac{dy}{ds}=\sin\theta\sin\phi,$$

$$\frac{dz}{ds}=\cos\theta,$$

so that with the same notation as before the energy equals

$$A^2\int\iota\left(U\frac{dx}{ds}+V\frac{dy}{ds}+W\frac{dz}{ds}\right)ds$$

$$=A^2\int\iota\,(U\sin\theta\cos\phi+V\sin\theta\sin\phi+W\cos\theta)\,ds,$$

so that if ϕ increases by $\delta\phi$, the alteration in the energy equals

$$A^2\int\iota\,(-U\sin\theta\sin\phi+V\sin\theta\cos\phi)\,\delta\phi\,ds,$$

so that the couple tending to increase ϕ, *i.e*, the couple whose axis is parallel to the axis of z, equals

$$A^2\iota\,(V\sin\theta\cos\phi-U\sin\theta\sin\phi)$$

per unit length of current; this may be written

$$A^2\iota\left(V\frac{dx}{ds}-U\frac{dy}{ds}\right),$$

hence the couples parallel to the axes y and x are by symmetry respectively

$$A^2\iota\left\{U\frac{dz}{ds}-W\frac{dx}{ds}\right\},$$

$$A^2\iota\left\{W\frac{dy}{ds}-V\frac{dz}{ds}\right\}.$$

The axis of the resultant couple is perpendicular to the element and to the vector whose components are U, V, W.

In another paper† Von Helmholtz discusses the force acting per unit of volume on a conductor traversed by electric currents; he shows that, according to the potential theory, if u, v, w are the components of current through an element $dx\,dy\,dz$, and X, Y, Z the components of the force acting on this element of volume per unit of volume, then

$$X=A^2\left[v\left(\frac{dV}{dx}-\frac{dU}{dy}\right)+w\left(\frac{dW}{dx}-\frac{dU}{dz}\right)+U\frac{de}{dt}\right]$$

* "Ueber die Theorie der Elektrodynamik," dritte Abhandlung, Crelle, LXXVIII. pp. 273, 324, 1874; "Gesammelte Werke," p. 723.

† "Ueber die Theorie der Elektrodynamik" Crelle, LXXVIII. pp. 273-324, 1874 *Gesammelte Werke*, Vol. II. p. 703.

Digitized by Google

$$Y = A^2\left[u\left(\frac{dU}{dy}-\frac{dV}{dx}\right)+w\left(\frac{W}{dy}-\frac{dV}{dz}\right)+V\frac{de}{dt}\right]$$

$$Z = A^2\left[u\left(\frac{dU}{dz}-\frac{dW}{dx}\right)+v\left(\frac{dV}{dz}-\frac{dW}{dy}\right)+W\frac{de}{dt}\right]$$

He then discusses the application of the potential law to sliding contacts—that is, contacts such as those made by a wire dipping into mercury; in the derivation of the forces from the potential law it is assumed that the displacements are continuous, and it might be objected that we have no right to apply the law in this case, as the motion of the wire and the mercury seems at first sight discontinuous. Von Helmholtz, however, points out that, as the wire carries the mercury with it as it moves, the motion is not really discontinuous and that Neumann's law is applicable. The question of sliding contacts comes prominently forward when we compare the various theories; we shall return to it again in this connection.

Von Helmholtz also in this paper investigates the electromotive forces acting on a conductor in motion; he shows that if the components of the velocity of the conductor at any point are α, β, γ, then P, Q, R, the components of the electromotive force, are give by the equation

$$P=\beta\left(\frac{dU}{dy}-\frac{dV}{dx}\right)+\gamma\left(\frac{dU}{dz}-\frac{dW}{dx}\right)+\frac{d}{dx}(U\alpha+V\beta+W\gamma),$$

with similar equations for Q and R.

He also investigates the difference between the results of Ampère's and Neumann's theory for the E.M.F. due to induction. The results are complicated; for practical purposes it is sufficient to notice that when there is a mechanical force tending to make the body move in a certain direction, there must be an E.M.F. when the body moves in that direction.

C. Neumann's Theory.

C. Neumann assumes that the electric potential energy is propagated with a finite velocity, and that if two electrified bodies are in motion, the mutual potential energy is not ee'/r, where r is the distance between them, but ee'/r', where r' is the distance between them, at a time t before, where t is the time taken by the potential to travel from the one body to the other.

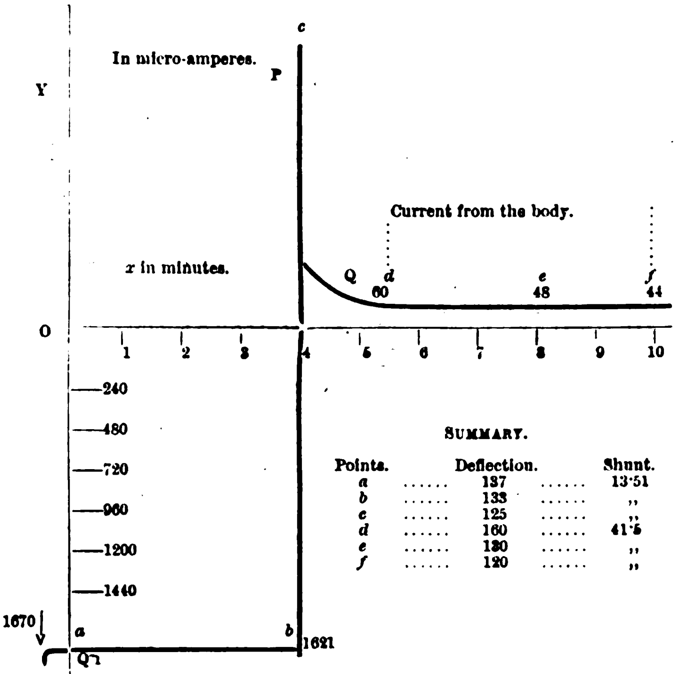
The energy considered in C. Neumann's theory is a kind of energy quite different from any that we have experience of; it is not potential energy, because that at any time depends only on the position of the system at that time; it is not kinetic, because that depends only on the position and velocity of the system at the time under consideration, whilst Neumann's energy depends on the velocity and position of the system at some previous time. In spite of all this, however, Neumann applies the ordinary dynamical processes to this energy just as if it were kinetic or potential; and in this way arrives at the same expression as Weber for the force between two moving electrified bodies. The rest of the theory is the same as Weber's, except that Neumann's assumption about the nature of a current is different from Weber's. According to Weber, an electric current consists of equal quantities of positive and negative electricity, moving with equal velocities in opposite directions. According to Neumann, the positive electricity alone can move, the negative being attached to the molecules of the conductor. Riecke and Clausius have shown that with this assumption and Weber's law a steady current must exert a force upon a particle at rest and charged with electricity, and must in consequence produce an irregular distribution of electricity over any conductor in its neighbourhood.

(To be continued.)

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

LECTURE II.

Dr. Stone: Mr. Vice-President and gentlemen—In the first lecture I made some observations as to the resistance of the human body. I took it that it has been enormously over-estimated, and that the first difficulty was due to the fact that insufficient contacts had been obtained. I showed also a system by which a sufficient contact could be obtained. I ought to have mentioned that I verified the fact that skin resistance was entirely eliminated upon the corpse. After taking the observations I spoke of with the wetted poles, I thrust two long silver needles into the feet of the dead body, and took another determination, and it came out; although the needles were thrust into the muscular tissue, the resistance was higher than what I had had before. I then showed that another difficulty was due to the fact that the human body rapidly electrolyses, and that a current of polarisation is set up, which is of very considerable power. That topic I wish to go into more closely to-day. I indicated the direction in which it is best to take the current—from hand to hand, from foot to foot, and from hand to foot, and through other parts. I observed, too, that the size of the patient did not seem to make any great difference in the resistance, because tall men gave, if anything, a lower rather than a higher resistance than short men, the physiological law clearly coming out as the length of the lever in a body so is the area of the muscles that move it. I gave certain examples, and I mentioned an interesting determination which I had been able to make with the assistance of Mr. Lant Carpenter. To-day I do not wish to speak of the electrolytic action which takes place when a current passes through the body. Now, all fluids are electrolytes, and it is somewhat difficult to measure their resistance in every case. So are bodies imbibed with fluid, and on this subject there have been made exhaustive researches—a long one by Du Bois Reymond; and I mentioned another one, which I shall refer to again, by the Count du Moncel. In the next place I shall show that the current that has to be taken back again was an ordinary fluid resistance which has been charged in the usual way. I will now charge and discharge two little cells connected by a fine tube, which may be looked upon as a sort of electrical schema of the human body. [Experiment.] In this case the resistance is about 1,340 ohms, and the solutions which I use are the same as those which I made use of before. This is only a tube of salt and water about 2 millimetres in diameter, yet it takes fully 10 minutes to charge it, and even then with difficulty. It is easy enough to see the effect by a sensitive galvanometer, and I hope that I shall be able to demonstrate it. But I must wait some little time until it is properly charged, and in the meanwhile I will make some further remarks. This polarisation, of course, appears as an increased resistance, and, besides the Count du Moncel's observations, there is an excellent paper on the subject by Drs. Waller and de Watteville in the *Philosophical Transactions* for 1882, which I shall have to quote presently. I found when I came to make these charging and discharging observations that two things happened. There is an initial throw, and the galvanometer gives a great start, and then it permanently remains deflected. At first I attributed this initial start to something of the nature of a condenser action, and I stated this fact at the meeting of the British Association at Aberdeen. I have been led by Prof. Hughes's researches to somewhat modify my views on this subject since then, and I wish only to mention that I think it might better be designated under the name of self-induction, which I shall speak of slightly to-day. At the third lecture I shall show that the self-induction takes place during variable periods of current, and that with this constant current it is not very visible. This galvanometer is only intended to show the permanent deflection. Now, this counter-electromotive force is considerably greater than I had anticipated. Presently I shall give you a very excellent measurement, made independently of myself, and which is represented by the two curves on the diagram in the gallery. The upper curve shows very beautifully what happens. The first part of the curve below the line in the middle is the period of discharge. All the measurements are given. Then the discharge takes place where that vertical line is. The galvanometer shoots up to the point C, and comes down again, but not to the line of zero.



SUMMARY.

Points.	Deflection.	Shunt.
a	137	13·51
b	133	,,
c	125	,,
d	160	41·5
e	130	,,
f	120	,,

On the contrary, it remains steadily, and for a very considerable time—very much longer than I anticipated—discharging through the galvanometer without losing its charge. In that case there are ten minutes given, and the fall in the current I shall speak of presently. In many cases I have been able to produce a much larger effect

Digitized by Google

than that. That is intentionally taken with a small current, so that we shall be able to measure it with a not very delicate galvanometer. But where you use a larger electromotive force the quantity discharged is very considerable. I therefore will mention some cases in St. Thomas's Hospital, where electricity administered was not purely for experimental, but for electro-therapeutical purposes. The first is a case of sciatica. The patient was very much atrophied in the leg, and, consequently, the resistance was somewhat high. It was about 1,900 ohms. I charged him for 30 minutes with 10 bichromate cells from foot to foot, putting the proper pole to the diseased limb, which, I may incidentally remark, resulted in a cure. But when I discharged through a galvanometer I had to somewhat reduce and modify the indications. The first throw was not less than 250 scale divisions—a very large throw indeed. I then discharged the lead poles, to see if they were doing this work, and they gave hardly any deflection at all. They gave only 20 scale divisions, so that it was actually the patient, and not the electrodes, which were charged. I then passed the same charge through a condenser with a ⅓-microfarad capacity, and I got a scale deflection of 30, and somewhat more than the poles gave me, but infinitely less than came through the patient. That was the first case. In the second I gave a constant current of 14 volts for half an hour from forehead to both feet immersed in a vessel of water. This was a case of diabetes, and you are perhaps aware that Dr. Mariano Semmola has proved that there is a decided decrease of sugar under the influence of a constant current. The resistance here was only 600 ohms, obviously because the conductor was duplicated. I corrected this by Sir Henry Mance's method, and the resistance came down to 543 ohms. There was a polarisation current of no less than 137 ohms representing all that amount of difference. The third case which I have to quote was another case of diabetes, in which the resistance was taken in the same way, but only with 6 volts from forehead to both feet. The man could not stand more, for he was extremely ill, and, indeed, eventually died. There I got 1,100 ohms, but corrected by Sir Henry Mance's method it came down to 1,025 ohms, of which the polarisation current represented no less than 145 ohms. This is a very large counter electromotive force, and much larger proportionately than would be expected and more than was demonstrated before. I will discharge this little schema of an electrical man through the galvanometer, but I am afraid it will not be a great resistance, the quantity is so very small—but I think it is visible. [Experiment.] That will go on for some time before it comes back to zero. I wish to charge the human body, and keep it charged for some time. I will substitute the real man for the schema. Here again I shall not be able to do the experiment immediately. The resistance of the real man is somewhat less, but not materially less, than that of the schema. Whilst that is going on I will go on with the measuring experiment which I mentioned before, and which I owe to the kindness of Mr. Lant Carpenter and his assistant, Mr. Wilkinson. Some of the resistance determinations I gave at the last lecture, if you recollect. The diagram is up there, as I thought we might be referring to it again [indicating diagram]. One cell of 2 ohms was put on for four minutes, and the actual resistance of the patient at the end of the first minute was 1194. It rose by polarisation to 1230 ohms. The current passing was ·0016 ampere. The resistance then remained steady, and stood at 1155, as you see there. Then comes the test for capacity, and it was by these tests that I came finally to the conclusion that capacity was not the right name for this action, although something of the nature of piling up of the current, which is now better called self-induction, most undoubtedly does occur. In the first experiment two cells were kept on for four minutes, and all the details of the experiment are very beautifully given [indicating diagram]. There was a shunt of one ohm. The discharge at the end of the time was 185 divisions of the same shunt. Then the leakage was measured. The leakage between my two baths I could not prevent, although they were on an insulating material. There was a leakage equal to 142 divisions. Now, this deflection is only ·043 per cent. of the test, and may be altogether neglected. I then tried whether the baths on the floor took any charge themselves. The deflection was 268 divisions, but this is only ·025 per cent. I think we may say that both these tests came out in favour of the accuracy of the observation. Ultimately the resistance then comes out to what I have there, 1,155 ohms. That was with a current of ·00346 ampere. I will now pass on to what is more easy to follow. We then discharged the patient himself, with no battering circuit. It was through the same galvanometer and under the same conditions exactly, and we got a current from him equal to 60 microamperes, and three minutes after that it had fallen to 48·7, and two minutes after that it had fallen to 45. Now, I thought that so important that I have enlarged the curve and given it you here on two diagrams. [Indicating.] Here is the first, and here are the minutes on the horizontal line, and here is the fall of the current. It is very nearly a straight line, and you will see that it discharges itself very much after the fashion of a secondary battery. I was not even satisfied with that, and I gave my two kind assistants a little more trouble. I asked that the curve should be plotted out in which the original throw, the condenser action, should be blended with a careful appreciation of the charging and discharging current, and I have no hesitation in saying that it is a very beautiful curve indeed. It opens a grand field for electrical inquiry as applied to the animal body, and more especially the human body. It hardly needs explanation. Here is the charging current. At the point B [indicated] a discharge takes place, and up goes the galvanometer to C, and then it comes down to this point, and this is carried on for ten minutes, and the fall of the current is very regular and very slow, as you perceive. Before the galvanometer came back to zero would certainly be several hours. This is only from 2 volts current. We then went on to see how much of this throw would occur with the needle swinging under its own inertia. Another test was therefore taken under the same conditions, using an inert instead of a polarisable resistance—using an ordinary resistance instead of the man (the same patient, I may say, was used in all these observations), and the needle did not reach its previous position and did not fly out so far. Therefore the difference between these two must absolutely be the measure of the difference of the polarisation which took place. There is the test. [Indicating it on the diagram.] That is a small quantity. But the electromotive force was very small indeed, only just competent to combat the counter electromotive force. Water can hardly be decomposed with a single cell, and we were only using a single bichromate cell. Yet we got that very decided difference, which I think completely proves what I have been contending. The result of all this is that as regards the electrostatic capacity of the body it is very difficult to separate polarisation from capacity; and perhaps it is wiser not to say that it is capacity, but that there is a self-induction. Now, after the 10 minutes I think I can discharge my human condenser directly. [Experiment.] I am happy to say it is quite visible.

This has a very important physiological bearing, and the bearing is on electrotonus. I confess I have always been sceptical as to the reality of electrotonus. Every writer seems to inveigh against its inconstancy, and the difficulty of getting results, not to say the reliability of the results when they are obtained. Here, for instance, is the last work of Rosenthal, who says: "It sometimes goes one way and sometimes the other, and there have been great disputes as to it." I will not read the whole passage, because time will not allow of it. Then here is an excellent though rather bulky volume, containing the remarks of Drs. Waller and de Watteville. It mentions various authorities, and goes on to say: "In a determination on the ulna nerve, Eulenburg and other observers simultaneously came to opposite conclusions. He attributes the inconstancy of the results to the inconstancy of the nervous matter, a view which was followed by many physiologists. Every one of them assumes something, and all their results are heterogenous to the last degree; there is obviously something wrong somewhere. I have felt that for a considerable time, but I hope we are on the way now to see what is wrong. I do not in the least deny that such an action as electrotonus does take place. But too much stress has been laid upon physiological points, and the investigation has been carried on without looking to see that the physical agent is constant in all conditions, and acting under the same circumstances. For instance, Rosenthal lays such great stress in the very first quotation on anode and cathode, though anode and cathode are purely fictitious terms. He considers that the current goes from the anode to the cathode, but we have no means of knowing that it does. It may go the other way. We call the one plus and the other minus, and we have to assume the upward and downward movement or the influence of the two poles. This is the first assumption. But we do know something else about the two terminals by electro-chemistry. We know that at the plus terminal in an electro depositing apparatus oxydation takes place, and at the minus terminal hydrogen comes off. We know in this way that if we are not working at the deposition of metal, but take a different body, we get a secondary battery, and I have not the smallest doubt from these observations that the effects are effects of electro-chemical decomposition. No doubt that chemical decomposition will transmit excitement along the nerve, and make the muscle contract, and the inconstant results obtained are due to chemical decomposition of the nature of polarisation. Now, we are always finding in books such phrases as these—which are thoroughly unscientific—"when the currents are weak the neutral point lies near anode, when they are strong it is situated nearer the cathode. When the currents are of a certain medium strength it remains at an intermediate position—that is, exactly midway." Now, what is medium strength? I want it in amperes—in some physical measure. You do not get it anywhere. But I do know that the medium strength, where the balance is maintained, is a strength which exactly balances the counter electromotive force of the body, and that is somewhere below a volt. When you get up to two volts, you see that the electro-decomposition is clear enough. The certain medium strength which ought to be measured, and must be measured, is the balancing electromotive force of the body. And the currents that have been used, as a rule, principally by Du Bois Reymond, are infinitely too strong for accurate determinations. He talks of using 11 or 12 Grove cells, but I should be very sorry to pass them through a patient without great precautions. An accident might occur from that. In fact, in the case of the Count du Moncel, an accident did occur, and he used 8 Daniels, which is 8 volts, whereas 11 or 12 Groves would be about 24. I think I ought to say, as I do not want to be misrepresenting Rosenthal, who is a very able man, and one of the great electricians of the German school, that he frankly makes the admission that the currents are inconstant. "If," he says, "a continuous current is passed through a nerve, and is alternately closed and opened, the excitement appears to grow irregular, sometimes at the closing and sometimes at the opening of the current, and occasionally even at both." There is another error which runs through the physiological observations, and that is what is called the tetanizing key of Du Bois Reymond. It is a short circuiting apparatus, as the electricians call it. It puts a good conductor in the course of the current, and is supposed by physiologists entirely to cut off the electrical agency from the large loop conductor outside, but it does nothing of the sort. The law of double circuits is that the currents are divided in the inverse proportion of their resistance, but there is no law that the resistance in a large circuit is completely stopped by Du Bois Reymond's key. Du Bois Reymond's tetanizing key has been another source of inconstant effects. Rosenthal, who was a distinguished pupil of Du Bois Reymond, says, speaking of the key: "The lever is made short and thick, and being made with a short, thick piece of brass which offers hardly any resistance, while the muscle offers great resistance, the current nearly all passes through the key." This is not a scientific or satisfactory arrangement. It should be none or all. When

Digitized by Google

we add to a constant current the induction coil, the problem becomes infinitely more complicated; and when we do as some observers have done—when we add a continuous current and an induced current to one another, to the same stream—I am quite certain that the problem is physically past solution. They have done more than that. There are induction coils now made in which the current of the primary is transmitted through the secondary complex circuit in that way, and then the continuous is added on, all unmeasured, piled on the top of one another, and no wonder the effects are inconstant. One does not know which way the current will run, and which predominates over the other. Next comes a most distinct false assumption, which I hope to prove to you at the next lecture, and here I may be doing Dr. Waller and de Watteville an injustice if I did not read the following passage. I will not read, however, the whole. He speaks of using a constant current and an induced current as the mode of producing electrotonus. He says, respecting the testing current, whether galvanic or induced: "Since the laws of diffusion are the same for both." I do not believe the laws of diffusion are the same for both, and the fact upon which I found that belief I shall demonstrate to you at the next lecture, for whereas my patient gives 1,100 ohms resistance to the constant current, even when corrected for polarisation, to the induced current he only gave half that. This is a most important fact which I *lately* discovered. An induction current will pass through the body and give only a resistance of about ½ to ⅔ under a constant current, even when corrected in every way for polarisation. Here is a case where it is curious to observe what happened. The patient gave a resistance corrected by Mance's method of 1150—it really came out a little below that, but we will call it 1,150. With an interrupted current he gave a resistance of 575, the exact figures being 1,141 against 575. It is very nearly 2 to 1. Therefore the laws of diffusion, I say with confidence, are not the same for the two. What may be the cause of the difference I do not know that I am quite prepared to say at length. But this fact must have a physical origin. I will take that up more largely at the next lecture. I explained at the last lecture that we have in the telephone an instrument by which we can reproduce physically many forms of testing machinery which were formerly of a physiological character, and the observation is so interesting that I shall ask you to allow me to go a little more into it to-day. If you will kindly take down the telephones I will at once proceed with the experiment. I have an interrupter here with which I can make and break a current at different paces; and here you will be able to discover that the result is not only audible, but if you listen carefully you will hear that the ticks given by one and the other act are considerably different. [Experiment.] There comes a period if I slide the sledge along when the tick of making contact disappears. It goes gradually down and fades out. The one tick fades away and leaves the other. Now, this is exactly what has been shewn in galvanoscopic frogs, as a means, as it is said, of getting pure excitements. But it is nothing more nor less than what is due to that physical action. This can be done without a frog, at a distance, with a telephone replacing the frog. Therefore, I hope I have carried conviction to you. To me it seems very plain that what Dr. Walker admits when he says that we are dealing with physiological signs alone has been a somewhat dangerous course of action, and that that error has arisen from not measuring our instruments more carefully, and that the prospects of advance in this direction will be by building up from the foundations; by ascertaining what is the force we are using, and how it acts; and then on the top of that to put the physiological determinations. Many of the observations that have been made—and they are very exhaustive (even Du Bois Reymond's volumes alone are the work of a lifetime)—are very interesting, if not convincing. There is another point which has stood in the way of accuracy, and that, I may note, is that over-sensitive galvanometers have been employed. The delicate Thomson galvanometer—beautiful instrument as it is—is so very sensitive that it requires to be somewhat heavily shunted, or you can hardly handle it. The same thing applies to the galvanoscopic frog. We have no means of calculating the accuracy of that. Probably no two prepared frogs have exactly the same power, neither do I see any way of obtaining it. It used to be said we moved up from electroscopes to electrometers when Sir Wm. Thomson discovered the method of measuring in real units. We want to move from galvanoscopes and from physiological shades of action to those which will measure resistance with accuracy. I have great hopes that the telephone will be of service in this way. The telephone is an exceedingly delicate instrument. It is so very delicate that it almost has the fault of delicacy; but we have the power of improving it, and I will show you at the next lecture that we can use it so that it will take the place of a galvanometer in the ordinary Wheatstone bridge current, if you will only interrupt the current; but not in the way in which it is interrupted in an induction coil, but by a small chronometer. Then by our interruption current the telephone gives a tick and it can be silenced when the two resistances are equal, as in the usual case of the Wheatstone bridge, provided however that the two currents are equal in self-induction. The beautiful instrument of Prof. Hughes not only measures by means of the Wheatstone bridge, but using the telephone as a galvanometer measures resistance and also the self-induction. I find that these physiological substances exhibit a very considerable amount of self-induction. There is even a better plan suggested by Lord Rayleigh, although it was originally theoretically produced by Clerk Maxwell—that is, coiling two wires side by side, and making one of them a closed circuit, pass the current through the other, and that I expect will be the way in which we shall be able to measure the self-induction of differences of compact bodies like the human body. In the meantime, I feel sure that much that has hitherto been done will prove to be purely physical, that the investigation, although laborious, has been greatly misunderstood, and, in some cases, ingeniously misinterpreted.

PROF. FORBES' CANTOR LECTURES.

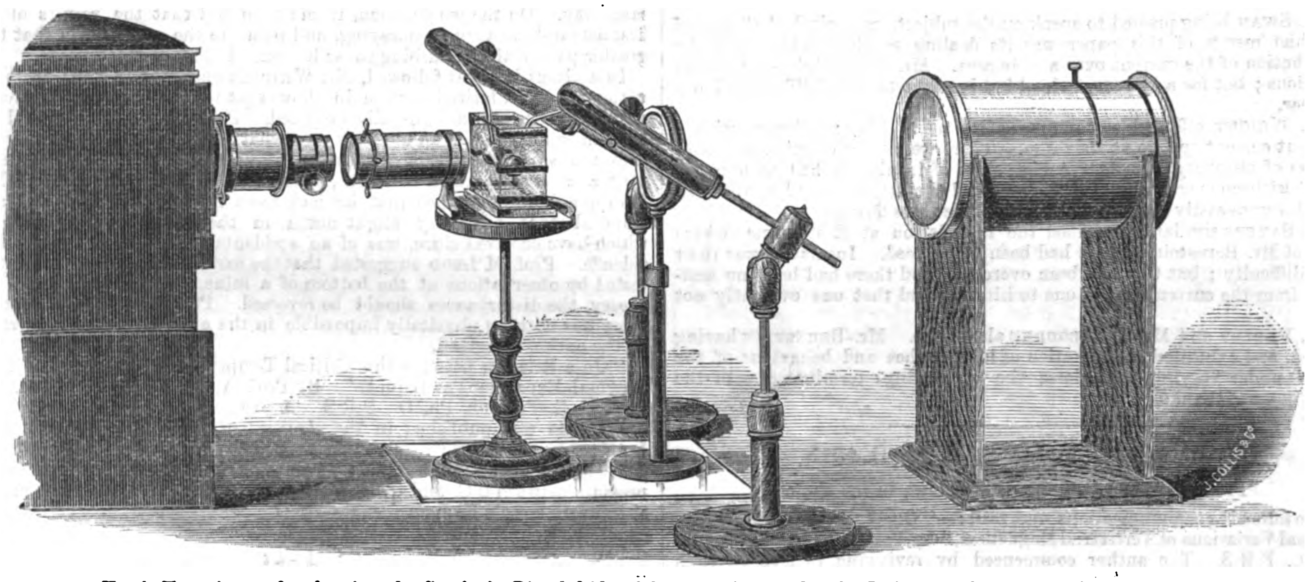
LECTURE I.—*(Concluded from page 441.)*

Now, when I have been showing you these phenomena of attraction and repulsion, I would ask you whether you are fully satisfied with the old view which used to be held, according to which electricity is a fluid material which settles upon the surface of electrified bodies, and, acting across the intervening medium, produces by a kind of action at a distance attraction and repulsion upon other bodies. It seems inconceivable to me that these actions can take place at a distance without the intervention of some medium between the mutually acting bodies. The existence of such an intervening medium seems to be essential to a conception, which we may eventually arrive at, as to the action of electricity and the action of gravitation. Such a medium we are almost certain does exist. The theory of light has almost conclusively proved to us that there is such a medium pervading all space. Whether or not that is the medium which is producing electrical phenomena and gravitational phenomena I will not venture to assert. But Newton asserted his incapability of realising the action of force at a distance, and every philosopher I think must feel the same instinctive aversion to the notion of force acting at a distance without some intervening medium. I have spoken about the Leyden jar. A Leyden jar consists of nothing more nor less than two conducting substances separated by an insulating material such as glass. It is made in the form of a jar, because there is less chance of the electricity passing from the outside coating or conductor to the inner coating or conductor. It was first discovered by a glass vessel being filled with water, which a philosopher was trying to electrify. He was holding it on the outside with his hands, and by making a contact with the inside he was actually getting that shock which you saw me get by connecting it with the outer coatings. Communication is of course taking place between these two coatings, and the nearer the coatings are together the greater is the communication. By having a thin piece of glass, we are able to have a powerful communication; but we must not make our glass too thin, because there is a certain strength beyond which the glass does not go, and if we exert it too far we pierce the glass and fracture it. Now, you will notice that this introduces the notion of a strained glass—that between the two coatings there is a strain between the two surfaces, and this is a notion which was thought of by Faraday, and which he developed into the conception as to the nature of induction which is universally held by electricians. He supposed that in these phenomena of attraction and repulsion the whole action is taking place in the medium between the two conductors. He showed it was impossible to give an absolute charge of electricity to one substance without giving an equal and positive charge to another substance; and there must be a course of induction between the two electrified bodies which are separated by an insulating medium, such as the air. I will make an experiment with a Leyden jar to show that to you. Here I have a Leyden jar which has the parts capable of being separated. Faraday's view was that the conductors are not electrified, that it is wrong to speak about the conductors being electrified, that the whole of the phenomena is in the glass, and that it is the straining medium by this new inductive action which produces the whole phenomena of electricity. I will now show you that Faraday's view was, so far, correct—that the charge undoubtedly does exist in the glass, and not in the electrified body. [Experiment.] I had discharged the outside and I had discharged the inside; I had left the glass strained, as Faraday said it was strained, and having put its inner and outer coatings on once more I was able to get a spark from the glass which had continued to possess its strain. Now, if it is a case of strain, a material which is once strained takes a little time to get rid of its strain, and here is an experiment which will show you that this is the case. You saw I had a spark there; I had discharged this machine, and yet you saw I got a spark. I will get up excitement in this machine, and then I will discharge it. The poles of this machine are connected with Leyden jars. I will discharge the Leyden jars so that no more charge exists. They are discharged. I have connected them. But the glass in these Leyden jars is still twisted, and is gradually untwisting itself, and as it untwists itself it develops the electrical condition; and now I shall be able to get another discharge. [A very feeble spark was shown.] Sometimes I can get a considerable number of discharges in that way. I will show you that by a piece of material which is called dermatite. I will charge myself with this, and I will show you what a long time it takes to get rid of its electricity. Now I am pretty well charged. [To his assistant.] If you will hold up your finger I will give you a charge. [Experiment.] It is not a very distinct spark. There is another. [Mr. Davenport (the assistant) was able to take a third spark—a fourth, a fifth, a sixth, a seventh, an eighth, and a ninth. He was able to feel the ninth.] If it had not been that that material dermatite took a long time to get rid of its strain the first discharge would have completely discharged the electricity in my body; but because of the peculiar construction of the material, it takes a long time to get rid of the strain, and so the successive discharges are shown, as the strain is gradually going off. I will mention a striking experiment to show that this induction is a state of strain, which Dr. Hopkinson did many years ago—how to give a residual discharge from a Leyden jar. [By a delicate measuring instrument he showed the rate at which the strained glass was giving it off—the rate at which the difference of potential was diminishing between the inside and outside of the Leyden jar; and he tapped the jar mechanically in this way. [Shown.] We know that tapping it would make it get rid of its strain, and in doing so, while he was measuring the electricity from the Leyden jar, he trebled the quantity which was being given off by tapping it. I think this is almost a conclusive proof that the increase which takes place is really a condition of strain. This was

Digitized by Google

really the theory enunciated by Faraday. This was the theory worked out more thoroughly by Clerk Maxwell, and he showed that if we supposed the medium air, or whatever it is, to be exerting a tension where tension has taken place, and exerting pressure at right angles to that, all the phenomena of electricity and equilibrium can be thoroughly explained in that way. It would therefore be necessary to prove not only that there is a state of strain, but also that the direction of the strain is as predicted. This is a brilliant experiment, which was accomplished by Dr. Kerr, of the Free College of Glasgow. I am afraid, however, it is hopeless of me to show it to you. It is an experiment that has only been once or twice completed It is so very important, however, to show you an experiment which has actually proved to us that the theory of Faraday as worked out by Clerk Maxwell is true, namely, that the strain of an insulating medium is in a certain direction, that I did want to show it to you although it is somewhat difficult to do it. I will show you the form of apparatus at any rate (Fig. 1), and then I will do my best to show the result which Dr. Kerr got. You will pardon me if I fail in doing it. At the same time I will take this opportunity of showing you more powerful effects with Mr. Wimshurst's machine when it is exerted to its utmost capacity. Here is, meantime, an electric lamp, by means of which I shall show a beam on the screen on the wall there. I will throw a small image on the screen. I have an instrument here which is called Nichols' prism, through which the light has to pass, and I have to thank Dr. De La Rue for enabling me to show this experiment. This is Nichols' prism, which does not let any rays of light vibrating in the direction I have spoken of pass through it, and, therefore, when we have arranged Nichols' prism in that way, the one cuts off the light from the other, and we shall see no light on the screen. I now place a vessel, containing bisulphide of carbon, in a focus of the lens between the two Nichols prisms. I have two glass tubes with bulbs on their ends filled with mercury, and I have wires passed from the mercury and passed to wires which go to the conductors of the large Wimshurst machine. At this moment Nichols' prisms arranged to produce darkness. I twist one round its axis so, and a bright light is seen. Now, by twisting this Nichols prism I can produce complete darkness. Now, I shall be able to show you the effect of introducing into this a beam of light. If I introduce into this position any transparent substance in a state of strain it has the power of restoring the light in that central part. Light can be restored in the central part if I had a body in a state of strain. The brilliant experiment done by Dr. Kerr was to charge powerfully with a difference of potential of electricity, and then he was able finally to see light on the screen. There is far too much stray light about. I am afraid it will require the best of eyesight to see it. But there is nothing like making the attempt.

He concluded by showing the large quantity of electricity generated by Mr. Wimshurst's machine when it was exerted to its full capacity.



Kerr's Experiment for showing the Strain in Bi-sulphide of Carbon when under the Influence of Electrostatic Induction.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting of this Society on Thursday, the 8th inst., Prof. HUGHES, president, in the chair, the discussion was renewed on Mr. BERNSTEIN'S paper, read at the preceding meeting, on "Electric Lighting by Glow Lamps of Low Resistance." A group of these lamps constructed on Mr. Bernstein's principles, and fitted each with one of his switches, was kept alight during the evening by a Thomson-Houston machine.

Dr. FLEMING offered some criticisms on the paper chiefly relating to the misuse of the word "strain," and to the relative values of thick and thin filaments. With regard to the latter, he was of opinion that the life of the lamp depended on the homogeneity and uniformity of the carbon, not upon its thickness. As to the comparative danger of the two systems of high and low tension currents, he thought them about equal. In the one case insurance would have to be effected against fire, and in the other on life, only in the latter unfortunately compensation would not restore the loss. The chief difficulties in this country arose in obtaining perfect insulation underground, difficulties which, with their overhead wires, were more easily overcome in the United States.

Mr. MORDEY drew attention to the fact that at Brighton, Eastbourne, and other places, installations of glow lamps had been carried out, and were being successfully conducted on the series system. The lamps used, he believed, were usually of ordinary construction, arranged in multiple series, but he understood that, although lamps of such low resistance as Mr. Bernstein had been successful in constructing had not been used, some lamps of comparatively low resistance, made by Mr. Swinburne, had been tried, and, he believed, with success. These lamps took 3·3 amperes, and were of small candle-power. Groups of three of them were inserted in the circuits of the Brush dynamos. Mr. Wright, of Brighton, Mr. Sayers, who carried out the work at Eastbourne, and Mr. Swinburne were present, and he hoped they would give some account of their experience. He thought the author unnecessarily confined himself to a recommendation of lamps arranged in single series. While these would be useful where it was desired to turn lamps on or off singly, it would often be convenient to use groups of lamps in multiple series. He shared the common belief that it was of the utmost importance that lamps should have long lives. He held this opinion in spite of Mr. Preece's statement that it would be better to work lamps at a higher efficiency and with a shorter life than was usual; and also in spite of Prof. Ayrton's remark that the cost of lamp renewals was a very small item in the total expenses. Cost was not the only consideration. There were serious objections to short-lived lamps, as, for instance, the inconvenience and danger of a room or railway carriage being placed in sudden darkness. If lamps of high efficiency were used, he thought it would be an absolute necessity to provide duplicate lamps or filaments which could be automatically thrown into circuit in the event of breakage. Although in favour of series working he pointed out that this system must of necessity give shorter life of lamps than the parallel system, because in the latter when lamps became old the increase in the resistance enabled them to exercise a considerable preservative power—they then took less current; while in the series system, as they were always traversed by the same current, disintegration took place with continually increasing effect, and they approached their death very quickly, and not with diminished candle-power, as was the case with the parallel lamps. He supported the author's assumption of the possibility of maintaining the current constant. Constant current was a physical possibility; constant difference of potential in any distribution system was not. Mr. Drake had stated that it was difficult to keep the current constant, and that the Brush regulator for this purpose would not act; but he believed that Mr. Sayers had been quite successful in using this apparatus at Eastbourne, even for glow lamps, and he knew that it could be relied on. He could never understand the position taken by those who so strongly opposed high tension working, the advantages of which were enormous. Mr. Bernstein had done a great service in drawing attention at this time to this question, when, thanks to the teachings of Prof. Forbes and others, electrical engineers were in a position to consider such questions on their merits. He thought the constant-current method had been too much neglected, although he did not suppose that in ships,

Digitized by Google

and generally in compact installations, it would ever be used, as even in the cost of conductors it would have little or no advantage, a comparatively heavy wire having to be taken to each lamp; but for long lines the reverse was the case. He thought the author would find that a No. 6 wire was needlessly large for true economy in most cases, but it would be interesting to see what could be done with such a wire. With ten amperes passing through it, the density of current was only 300 amperes per square inch. The loss would be 14 volts per mile, or equivalent to 2·3, 60-watt lamps. This was only a loss equal to a 60-watt lamps for every 750 yards. He thought dynamos giving 3,000 volts could easily be used. The largest Brush dynamo gave nearly that E.M.F., and worked quite well. Such a machine would send 10 amperes through 215 miles of No. 6. wire. For every 750 yards taken off, a 60-watt lamp could be put in. Thus, on a circuit of twenty miles 450 lamps could be used, and even with this long line the conductor efficiency would be 90 per cent. He might put it in another way, as an illustration, and say that an arc lamp in a lighthouse 210 miles from shore could be worked by such a machine if a cable could be laid with sufficiently good insulation, using an earth return. He thought the objection to high tension on account of the danger was not well grounded; the danger was exaggerated. Although for four or five years he had been engaged daily in working with high-tension dynamos in the works of the Brush Corporation, there had never been a case of personal injury or any accident from an electrical machine, although in the same works there had been several accidents from non-electrical machinery. If the opponents of high-tension applied their extreme caution to other things, and carried their case, railways would disappear, and cabs and omnibuses would become a thing of the past. The world would sink to a state of almost absolute zero, when there would be very little motion, and that motion very slow. With regard to automatic cut-outs, he thought electro-magnetic ones were best. Prof. Forbes and others had objected to them on account of the energy absorbed. This was simply a question of construction—the energy could be reduced to almost any extent. In the cut-out of the Brush lamp, for instance, the energy absorbed was only five-eighths of a watt.

Mr. SWAN being pressed to speak on the subject, remarked that one of the chief merits of this paper was its dealing so thoroughly with the distribution of the current over a wide area. Mr. Bernstein's switch was ingenious; but for a system of this kind it ought to be infallible, and not too dear.

Mr. WRIGHT afforded some information as to his experiences with a constant current system at Brighton. There were three circuits, covering an area of about eight miles. A high state of insulation had been maintained with no extraordinary difficulty, and the detection and localisation of faults were easily effected while the current was flowing.

Mr. SAYERS similarly described the installation at Eastbourne, where some of Mr. Bernstein's lamps had been introduced. Insulation was their chief difficulty; but this had been overcome, and there had been no accidents from the current except one to himself, and that one evidently not fatal.

Mr. VARLEY and Mr. SWINBOURNE also spoke. Mr. BERNSTEIN having replied, and exhibited the operation of his switches and behaviour of the lamps under varying conditions, the proceedings terminated with the usual votes of thanks.

PHYSICAL SOCIETY.—April 10th.

Prof. BALFOUR STEWART, President, in the chair.

The following communications were read:—"On the Cause of the Solar-Diurnal Variations of Terrestrial Magnetism," by Prof. BALFOUR STEWART, LL.D., F.R.S. The author commenced by reviewing various theories that have been advanced to account for the solar-diurnal inequalities of terrestrial magnetism. That they can be due to the direct magnetic action of the sun is highly improbable, since terrestrial analogies would lead us to infer that matter at the temperature of the sun is quite incapable of possessing magnetic properties, and also from the fact that changes in the range of the daily variation lag behind corresponding solar changes in point of time. The hypothesis of Faraday that the observed variations are the result of the displacement of the magnetic lines of force due to the varying temperature, and consequently varying magnetic permeability, of the atmospheric oxygen, is disproved by the fact that there is no agreement between the chief magnetic variations and those of the temperature of the great mass of the atmosphere, though it is certain that there must be some effect due to this. The earth current hypothesis is quite unable to explain one of the chief characteristics of these variations—that they are half as great again at periods of maximum as at those of minimum sun-spot frequency. Sir George Airey has, moreover, been unable to detect any resemblance in form between the regular diurnal progress of the magnet and that of earth currents. We seem, therefore, compelled to seek for the cause of the variations in the upper atmospheric regions, and we cannot imagine such a cause to exist in any other form than that of a system of electrical currents. That currents may, and actually do, exist at great heights is shown by the Aurora, which is unquestionably an electric current, and manifests a close connection with the phenomena of terrestrial magnetism. The great increase of magnetic variation at epochs of maximum sun-spot frequency can also be accounted for on this supposition. Prof. Stokes has remarked that an increase in the radiating power of the sun would probably imply not only an increase in general radiation, but a special and predominant increase in such actinic rays as are probably absorbed in the upper regions of the earth's atmosphere. These regions will therefore greedily absorb the new rays, their temperature will rise, and, as is known to be the case for gases, the electrical conductivity will be increased. Thus, even if we imagine the general atmospheric current to remain constant, a greater proportion of it would be thrown at such times into those heated portions which had become good conductors, but it is also probable that the current itself would be increased. Assuming the existence of currents at great altitudes, the regularity and general characteristics of the diurnal variations would seem to point to a direct magnetic action of the currents rather than to any general induced change in the magnetic system of the earth, which, to produce the observed results, would have to be of a very artificial character. The diurnal variation of the declination, attaining a westerly maximum at 2 p.m., north of the equator, and an easterly maximum at the same time south of it, would suggest the existence of currents flowing northward and southward from the equator to the poles, obtaining a maximum in each hemisphere about two hours after the sun had passed the meridian. To supply this flow we should probably have to assume the existence of vertical currents ascending from the equatorial regions of the earth. At this point Dr. Schuster has endeavoured to apply mathematical analysis to the subject From the recorded observations at Greenwich, Lisbon, Hobarton, St. Helena, and the Cape, he had shown that the work done by a magnetic pole describing a closed path in a horizontal plane at those places is equal to the work done upon it, and consequently no part of the ascending current can be enclosed by the path. Hence the potential at those places obeys the law expressed by the equation

$$\frac{d^2 V}{d x^2}+\frac{d^2 V}{d y^2}+\frac{d^2 V}{d z^2}=0.$$

From this, Dr. Schuster has deduced two possible expressions for the potential, one referring to a system of currents above our heads, and the other to one beneath our feet. From the first of these expressions it follows that for latitudes greater than 45° the maximum of horizontal force should coincide with the minimum of vertical force, and *vice versâ*, and this is actually the case at Greenwich; while the opposite should hold if the influencing system were beneath us. For latitudes below 45° the reverse of the above should be the case, and the observations at Bombay, though less decided than those at Greenwich, would seem to point the same way. On the whole, then, it must be said that the results of the first attempt are very encouraging, and point to the supposition that the greater part of the disturbing cause lies outside the earth's surface.

In a discussion that followed, Mr. WHIPPLE remarked that recent observations in high latitudes seem to show that the Aurora is not always at such a great height as is usually supposed. Prof. A. W. Rücker cited the well-known case when an observer saw what appeared to be a meteor fall into the sun, while, simultaneously, or nearly so, there was recorded a magnetic disturbance on the earth, as showing a direct solar action. Mr. Whipple, however, stated that he had recently examined this point, and believed that the very slight notch in the record, many similar to which have occurred since, was of an accidental nature, and a mere coincidence. Prof. M'LEOD suggested that the earth current theory might be tested by observations at the bottom of a mine, where, according to the theory, the disturbances should be reversed. Prof. ADAMS believed that there was nothing physically impossible in the existence of such currents as the author imagined.

"On a Relation between the Critical Temperatures of Bodies and their Thermal Expansions as Liquids." By Prof. A. W. RUCKER, F.R.S., and Prof. T. E. THORPE, Ph. D., F.R.S. A paper by the authors bearing the above title was published in the *Journal* of the Chemical Society of London for April, 1884. The substance of the paper was as follows:—Prof. Mendelejeff has shown that the expansion of liquids under constant pressure between 0°C. and their boiling points may be expressed by means of the very simple formula

$$V_t = \frac{1}{1-kt}$$

V_t being the volume at t°C (that at 0° being unity) and k a quantity which differs for different substances, but which may for any one substance be considered invariable between 0°C and the neighbourhood of the boiling point. From this law the authors have obtained, as a deduction, the following expression for the critical temperature (T) of any liquid

$$T_c = \frac{TV_t - 273}{a(V_t - 1)}$$

where V is the volume at t°C., T the absolute temperature, and a a quantity which is very nearly constant for all substances, and which was shown to be very nearly 2.

In a recent paper (*Ann. Ch. Ph*, March, 1886), MM. A. Bartoli and E. Stracciati have discussed both of these formulæ, and have applied them to cases in a manner never intended by the authors. They have expanded Mendelejeff's formula into the series

$$V = 1 + kt + k^2t^2 + k^3t^3 \ \ldots\ldots$$

which is a geometrical progression, and they have objected to it that the results of Piere, Kopp, Hirn, Thorpe, &c., do not give for the coefficients of t, t^2, t^3 quantities in geometrical progression. The results of these observers are given in the usual form

$$V = 1 + at + bt^2 + ct^3 + \ \ldots$$

but owing to unavoidable errors of experiment the constants c, d_8, of different observers differ very largely, and Mendelejeff's simple expression gives the results of all quite as accurately as the facts will allow. MM. Bartoli and Stracciati have then criticised the expression given by the authors, and have applied it to determine the critical temperature of water from its expansion to 200°C., whereas the original expression is only given as applicable as far as the boiling point. They have further recorded a number of critical temperatures calculated by the formula to tenths of a degree, for which the constant a would require to be known to ·025 per cent., whereas there is no reason for supposing it known to within 1 per cent. or more.

COMPANIES' MEETINGS & REPORTS.

The Indo-European Telegraph Company (Limited).

The nineteenth ordinary general meeting of this Company was held on Wednesday, at the Cannon-street Hotel, Colonel James Holland in the chair.

Mr. W. ANDREWS (the Managing Director) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: I have now to move that the report and statement of accounts be received and adopted.

Mr. H. WEAVER: I beg to second that.

The CHAIRMAN: That has been moved and seconded, but before putting it to the meeting I should wish to make a few remarks, which, I hope, will meet with your approval. It is, as you may easily suppose, gentlemen, a very satisfactory thing for us to be able to submit to a meeting a report so satisfactory—I think I may say that of its features—as the one I hold in my hand. It shows an increase of upwards of £18,000 over the report of last year, which in itself was not a bad one. The balance sheet seems to me to call for very little remark, unless there is any point which the gentlemen present wish to refer to. There is one item, however, on which I should like to make a passing remark, and that is the very small amount of the law charges—some £40 for the year. That, I think, gentlemen, is very satisfactory to us; I think it is probably hardly so satisfactory to my excellent friend, Mr. Bristow, our worthy solicitor, who has conducted our business in so satisfactory a manner that the law charges have been so very small indeed. Indeed, I can say this—Mr. Bristow has for some years been our legal representative, and on all occasions we have found whatever he has done has been done most satisfactorily. He has always, when necessary to apply to counsel, taken care to employ the most judicious gentlemen, and one of the results of of the action of our solicitor (I do not say all) has been that we are very clear of law charges. I really cannot think there is a higher praise to be awarded to any firm of solicitors, and I am very glad to see Mr. Bristow is present. Well, gentlemen, although we have made a sum of upwards of £18,000 over the return of last year, the actual expenditure on every account is somewhat less than that of some years. That I look upon as one very satisfactory feature. There is an increase of about £1,600, in order to enable us to work the much greater traffic we have had; but the increase is more than negatived by the improvement in the accounts for the maintenance. Now, that I look upon as a very satisfactory point indeed, that our maintenance year after year, for some time, has been improving. Much has been done to keep it up to a high state of efficiency, and I think it is next to impossible that anything could be better than the maintenance of our line at the present time. Notwithstanding that great improvement, the cost for the year is some £1,700 odd less than that of the preceding year, and if anything could add to the deep debt of gratitude that you all owe to my worthy friend on my right, Mr. Andrews, I think that that fact alone will come to your hearts, and I think a shareholder's heart is generally said to reside in his breeches pocket. Another reason why this satisfactory state of things has been brought about, after according all due credit to our manager, has been that we have taken care from the beginning never to increase our capital charges. Whatever expenditure has been incurred has been from revenue. From day to day the expenses are paid up and we have nothing lurking behind to give us the least degree of apprehension. We find all our costs paid as they are incurred, and the capital in no respect watered. We hope that we shall be able to carry on the system to the end, and I see no reason so long as we carry on the system and largely increase our reserve fund but that the same satisfactory progress may be relied on year after year. I have said before that the line is in a most efficient state, and you must naturally infer from that circumstance that we must go on realising the large profit that we have done for the present year; but, gentlemen, I am sorry I must put a damper upon any extravagant hopes that are raised in this direction, because in the first place, if you look to paragraph 8 of our report, you will find that the profit is exceptional. We state here "The large augmentation of revenue is quite exceptional, and is owing to the total interruption of the Eastern Company's lines for some three weeks, the disturbances in Burmah, and the Afghan Frontier question, and it is satisfactory that the £18,046 of additional revenue has only occasioned an increased expenditure on commercial account of £1,637." So, gentlemen, you must not expect this kind of revenue every year. War and political disturbance, which in this particular year has proved so exceptionally beneficial to us, is like a two-edge sword, it cuts both ways. We have had the sad experience of what war can do, to our great discomfort and annoyance, in the war between Russia and Turkey, in which some sixty miles of our line were destroyed and our revenue totally put a stop to for a considerable period; so that, although war sometimes, as in the past year, has been beneficial to us by the great amount of political intelligence that it is necessary to convey over our lines, yet it may be just as damaging on the other hand; and, therefore, we must not reckon upon war being a friend to us. Our truest friend is commercial prosperity. That, unhappily, has been and is at a very low ebb, but all we can do is to hope that things may mend. We trust that they may, because that is the real substantial prosperity that will last us for a considerable period. Well, then, in order that the prosperity may be beneficial to us, it is necessary that we should do our utmost to make friends of the commercial public. There are two modes of doing that. The first is to see that the line works in a most efficient manner. It is my belief, from close inspection of the matter, that it is impossible that the line can work better than it does at present, and I have stated to you to whom the credit is mainly due. The merchants, no doubt, are very well satisfied; in fact, I know they are, and must be, satisfied with the way the work is done. But they will also very likely say, "But, gentlemen, you charge a heavy price for your work; the work is very good, but the price is very costly." It is true it is costly, but the maintenance of a line in a thoroughly efficient state to India must at all times be a costly matter. We have, however, in consequence of the prosperity that we now actually enjoy, and in the hope that trade will improve, at the last quinquennial conference of different telegraph authorities of Europe proposed that the 4s. 7d. rate per word should be reduced. It was, after considerable discussion on all parts, in which our general manager, assisted by our able accountant, Mr. Mall, took a leading part, and under the presidency of a very distinguished statesman, Dr. von Stephan, the German Minister of Postal Telegraphs, and aided also by the good offices of a very illustrious member of a very illustrious house, Dr. Werner Siemens, himself a German resident at Berlin, who gave his best assistance to our endeavours, and with all these gentlemen present, and the Indian Government being anxious also to see such reduction as could fairly be made, we have reduced the rate from 1st July next to 4s. from 4s. 7d. At the same time considerable reductions have been made in the Trans-Indian telegraph to China, Malacca, and very many parts beyond India—reductions varying from 1s. to 1s. 6d. a word, all of which I see have been published, and, therefore, you will hardly desire me to read them over, although I have the printed list before me. Well, gentlemen, I have brought in the reduction of the tariff as one of the arguments to show that you must not expect an overwhelming profit year by year, because you must bear in mind that every reduction made on the tariff tells upon the gross receipts that the gross profits and the net profits are two very different things. The fact is the loss of 7d. to us is equal to about double the loss, being on the gross profits, whereas we have to pay you out of the net profits. In addition to this reduction of rates we are now considering with the Post Office and with various other companies a very considerable reduction in the press rates. A previous reduction of the press rates was originally proposed by our Company, and it was carried out in the first instance by the Indian authorities, who are, as you are aware, partners with us in this concern. It is a very satisfactory partnership in one respect, because the influence of this powerful Government — the Indian Government—shields us to a great extent from unreasonable competition, on one condition. That condition is that our line works in the most perfect state that is possible. The moment we let the maintenance fall, or the working become inferior to what it is, and to what it has been for some time past, we are liable to find competitors in the field. But, gentlemen, we trust that is a matter that will not occur. It certainly shall not be from any want of exertion on our part. Then, again, we must always bear in mind that our line is a very excellent and a very perfect one; in fact, more perfect now than when it was first constructed, because not only do we repair everything that goes wrong during the year, but as science and experience improve and increase from time to time, we improve the line in accordance with the latest improvement. But notwithstanding that it is only valuable as a going concern. If there were some convulsion—political convulsion—that were to destroy the line, it would be of no value whatever. I mention that simply as one of the many arguments for keeping up and greatly increasing our reserve. Well, gentlemen, I think with those few remarks, which I am afraid have been rather tedious, and which are all I have to say at present, I will submit the resolution I have read to you.

A SHAREHOLDER: Some misconception might arise from your remarks about the reduction of the tariff; it is to be hoped that the increase of traffic may compensate for that.

The CHAIRMAN: Well, it may or it may not. We always have the hope that where a reduction of tariff is made it may lead to an increase of traffic.

The motion was then put and carried unanimously.

A dividend for the half-year of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 30s. per share, both free of income-tax, making 12 per cent. for the year, were declared.

The retiring Directors and Auditors were re-elected; and a vote of nks to the Chairman and Directors then terminated the proceedings.

The Oriental Telephone Company (Limited).

The sixth ordinary annual general meeting of this Company was held on Tuesday last at the City Terminus Hotel, Cannon-street, Mr. W. Addison presiding.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting, and the report of the directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, before moving the adoption of the report I will proceed to make a few remarks, and I think I shall be able to show you that the progress of the Company for the past year is more satisfactory than would appear from a cursory glance at the accounts. You will see that the balance-sheet we have issued is in a different form to previous ones, and which we believe the general public will be more readily able to understand. Our holdings of shares in the different companies are set out in a simpler and more intelligent manner, the deferred shares not being included in the valued assets, although as the terms for the guarantees draw near they really become a very valuable property. In noticing the accounts you will in the first place see by a note in the profit and loss account that a sum of £935 taken credit for last year really belonged to the year before—that is, to 1883. It represents the amount of guaranteed interest on the Bengal and Bombay Companies' shares held by this Company for that year, and that was the way in which it was dealt with by the auditors,

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.
Digitized by Google

whereas for the year 1885 it is for 12 months only. The accounts this time are charged with an item of income tax, £122, which really does not belong to 1885, but to the previous twelve months. The income-tax becomes due every year in April, and it has been the custom heretofore to charge it only when actually paid. We have debited the accounts this time with three-fourths of the income-tax, that brings us up to December last. I am happy to say that although we were assessed by the commissioners of income-tax to the amount of £146 last year, owing to our representation that we were not paying a dividend, they have, since the issue of the report, allowed our claim for exemption. In reference to the sum of £480 written off for depreciation of stores, half of that, I may say, hardly belongs to last year, as it is for material sent out in the early days of the Company, which has become practically obsolete. We have had a loss of £350 at Colombo, chiefly due to reconstruction expenses and a defalcation at Mauritius, which, I am glad to say, is not so serious as at first expected. The last advices leave us to hope that £200 will cover this item, and our new agent there writes more hopefully of the position generally. I may remark that Mauritius is a very difficult place to correspond with. The mail from there generally arrives two days after the mail goes out. Consequently it takes about three months to get a reply. Unfortunately, all our exchanges are in towns particularly affected by the bad times, and the heavy fall of the Eastern exchanges has largely reduced our profits for the last year. During that time, however, the business in Egypt has greatly improved. The Directors of the Egyptian Company declared a dividend at the rate of 5 per cent. for last year, as against 3½ per cent. for the previous twelve months The shares are still valued in the accounts at less than half their nominal value. Since their accounts for 1885 were made out the business has steadily continued to improve. The Indian guarantees are gradually decreasing, but not so fast as we should like to see them. The Bengal Company for the last 12 months shows a decrease of £650 and the Bombay Company a decrease of £600. I may remind you that the guarantee to the former company expires in May, 1888, and to the latter in September, 1887. After these guarantees cease our deferred shares come in and share equally with the others, so that instead of guaranteeing 8 per cent. we shall be receiving a percentage on our holdings, whatever they may be. The total number of new subscribers is 537. On the other hand, the withdrawals, owing to failures and bad times, have been 206, leaving a net increase of 331. The total number of subscribers up to December 31st, 1885, was 1,889, as against 1,578 in December, 1884, and the total number up to the latest advices this year—which we may take to be the middle of March—is 1,984. These returns we think fairly good, considering the commercial depression existing everywhere. We have taken £500 for our remuneration for the past year, and propose to take only the same amount for the current year. In conclusion, you will see by the accounts that our financial position, with £2,000 on deposit at the bank, and nearly £1,000 on current account, and other £600 at our agencies abroad, is by no means an unsatisfactory one, and we trust the shareholders will think so also. I now beg to move the adoption of the report and accounts, and if any shareholder wishes to ask any questions before I put the motion I shall be glad to answer them.

The Right Hon. G. A. CAVENDISH BENTINCK, M.P., seconded the motion, which was carried unanimously, without discussion.

The CHAIRMAN then moved the re-election of Mr. Henry Grewing as a Director, and Mr. B. ST. JOHN ACKERS having seconded the resolution, it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. G. B. FROST, Mr. Thomas Lloyd was also re-elected to his seat at the Board.

Mr. BAKER in, a few words, warmly acknowledged the report and services of the committee that was appointed to investigate the affairs of the Company under its previous *régime*, and proposed that a cheque of 200 guineas be awarded to the members composing it, in recognition of their labours—a motion which was seconded by Mr. FITZGERALD and agreed to *nem con.*

Mr. FITZGERALD next moved, and Mr. CUFF seconded, the re-appointment of the Company's auditors, Messrs. Deloitte, Dever, Griffiths, and Co., at a remuneration of 50 guineas for the current year, which was unanimously agreed to.

Mr. BAKER afterwards proposed, and Mr. BUCKINGHAM seconded, a vote of thanks to the Chairman and Directors.

The CHAIRMAN having briefly returned thanks,

The meeting was made extraordinary, when,

The SOLICITOR to the Company, Mr. Joseph Addison (Linklater and Co.), said that it had been thought expedient to alter the Articles of Association in the direction of withdrawing from the Directors certain powers, which it was thought were too wide for them to exercise without the consent of the shareholders. He then proceeded to explain the nature of the proposed modifications, which were as follows:—That Article 56 of the Articles of the Association of the Company be altered by striking out the words "But this Article shall be construed as being only directory." That Article 60, clause (*a*), be altered by the addition of the following words:—"Provided that the total amount for the time being owing shall not, without the previous consent of a general meeting of the Company, exceed £10,000," To add the following words at the end of amended clause (*c*) of the same Article after the words "or other interests:—"But the authority hereby conferred is not to be deemed to authorise the sale of the entire business or undertaking of the Company without the previous consent of a general meeting." That clause (*d*) in the same Article be rescinded and the following sub stituted:—"They may from time to time appoint any one or more of their number managing director or managing directors, with such share or proportion of the remuneration payable for the time being under Article 58, and for such period as they deem fit." To add the following words to clause (*e*) of the same Article:—"Subject to confirmation at the next annual meeting." To insert in clause (*f*) of the same Article after the words "they may," in the first line, the following words, viz:—"Subject to the limitations imposed by paragraph (*a*) of this Article." That Article 61 be altered by the addition of the following words after the words "the continuing directors" in the first line:—"So long as their number for the time being is not less than five." That Article 64 be rescinded, and the following be adopted in its place:—"No contract or arrangement entered into by or on behalf of the Company with any company, corporation or partnership, of or in which any Director shall be a member or otherwise interested, shall be avoided, nor shall any Director being such member, or so interested, be liable to account to the Company for any profit realised by any such contract or arrangement by reason only of such Director holding such office, or of the fiduciary relation thereby established; but no such Director shall vote in respect of any such contract or arrangement."

On the motion of the CHAIRMAN, seconded by Mr. B. ST. JOHN ACKERS, the whole of the foregoing alterations in the Articles were agreed to, and the proceedings terminated.

Reuter's Telegram Company.

The report of the Directors of this Company, which was presented at the general meeting on the 22nd inst., states that in the circular issued last October, the shareholders were informed of the heavy expenses entailed by the successive campaigns in the Soudan and the Anglo-Russian crisis. The anticipations which were then entertained, that the exceptional state of political affairs had ceased were unfortunately not realised, the Servo-Bulgarian and the Burmese wars having followed immediately afterwards. The Directors regret that, owing to these causes, the results of the year's operations do not admit of a dividend being declared. They have, however, the satisfaction to announce to the shareholders that new arrangements have been entered into with the Press, which provide for future exceptional expenditure in time of war or prolonged political disturbance. The Directors regret to have to record the death of their esteemed colleague, Mr. James Sydney Stopford. It is not proposed to fill up at present the vacancy thereby created on the Board. Admiral the Right Hon. Sir John C. D. Hay, Bart., K.C.B., retires from the direction, but offers himself for re-election. The auditors, Messrs. Quilter, Ball, and Co., also offer themselves for re-election.

A report of the meeting of the shareholders will be given in our next issue.

NOTICE OF REMOVAL.—The Western Electric Company notify that they have removed to new premises at 79, Coleman-street, London, E.C.

NOTES.

OURAY-COLORADO.—A company has been organised to erect a telegraph line from Ouray to Montrose, and work on the line has been commenced.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd inst. amounted to £2,487.

PARIS.—MM. Leconteux and Garnier are putting the electric light into the *Magasins de la Belle Jardinière*, and will use about 200 Edison lamps supplied from a Breguet dynamo.

THE LAW COURTS.—The telephone will shortly be introduced into the Law Courts, for the use of the gentlemen of the long robe and others having an official connection with the courts.

A NEW USE FOR THE PIANO.—A new feat in the way of electric lighting is the application of cell storage to pianos. The case of the instrument conceals the materials for an illumination lasting over ten hours.

BENGAL.—We learn that the system hitherto in use at the Central Exchange of the Bengal Telephone Company is to be changed, and that the Magneto-Bell will take the place of the Law system throughout the company's exchanges.

DAMAGES AGAINST A CONTRACTOR.—*L'Ingénieur-Conseil* mentions a judgment passed by a Paris tribunal giving heavy damages against a contractor for electric light, because a valuable picture was burnt in a fire arising from defective installation.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd inst. were £1,999, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

ELECTRIC LIGHT AT CLUMBER.—At the celebration of the coming of age of the Duke of Newcastle, on Wednesday last, when a banquet to his friends and principal tenants was given in the courtyard at Clumber, the buildings were illuminated with the electric light.

ELECTRIC LIGHTING ACT COMMITTEE.—Mr. W. H. Massey, electrical engineer in the Royal Household, has retired from Lord Thurlow's Committee, in consequence of the action taken recently by the executive council with reference to the Bills now before the House of Lords.

ELECTRIC LIGHTING.—We understand that the Conservatoire des Arts et Métiers is to be lighted by electricity. The inauguration, we believe, takes place on the occasion of the meeting of the several scientific congresses which generally assemble in Paris during this week.

LIVERPOOL EXHIBITION.—The Liverpool Electric Supply Company, having secured the contract of the lighting of the "Shipperies" Exhibition throughout with the electric light, have placed the order for all the cables and wire required therefor with Messrs. Walter T. Glover and Co., Salford, Manchester.

ELECTRICIANS FOR CHATHAM.—An electrical staff is to be formed at Chatham Dockyard, from which a certain number of the best fitters are to be sent to Portsmouth. On the completion of a course of training they will return to Chatham, and form the nucleus of a permanent staff of electricians at that establishment.

ELECTRICITY IN MINES.—It will be remembered that the report of the Lighting of Mines Commission, objected altogether to the use of the electric light, in that it would not give any indication as to the state of the mines in reference to fire damp. We have at various times described electrical apparatus for indicating fire damp, and this week, in another column, we describe another instrument which comes to us from America.

MORE EXHIBITIONS.—The first International Exhibition under the auspices of the National Society of Science and Art will be held at Paris in the Palais de l'Industrie, so well known to many of us from the Exhibition of 1881, from July to November this year. One group is reserved for electrical exhibits. At the Maritime Exhibition at Havre, to be opened on the 1st May next year, the application of electricity to ships and maritime operations generally will form a prominent feature.

EARTH CURRENTS.—M. Mascart describes a considerable magnetic disturbance which began on the 30th March about half-past eight in the morning. The disturbance continued till the 31st, then got gradually weaker, and disappeared completely on the 1st of April. This phenomenon, which was observed at Parc Saint-Maur, had been noticed at the same time at the observatories of Lyons, of Perpignan, and of Nice. It will be seen that this storm is the same as that referred to in our note, p. 404, of April 2nd.

THE BUILDING TRADES AND ARCHITECTURAL EXHIBITION. The following firms were successful in obtaining awards at the recent exhibition at the Agricultural Hall:—E. Jacobs and Co. (gas engine), Julius Sax (general excellence in electrical appliances), Cordner, Allen, and Co. ("Byng" Telephone), J. Davis and Co. (scientific instruments, &c.), Sanderson and Co. (lightning conductors), W. F. Stanley (mathematical instruments, &c.), G. A. Williams (automatic oxy-hydrogen light apparatus, &c.), and Messrs. Howard and Haig (general electrical appliances, &c.)

A NEW LIGHT.—A new competitor to gas and electricity is said to be found in a new medium of light called the "Lucigen," for which, among other advantages, it is claimed that it yields an illumination equal to 2,000 candle-power actual, at a cost of about 2d. per hour, while the cost of the necessary plant is one-fourth that required for electric lighting. The Lucigen is produced by burning heavy hydro-carbon oils in a specially made burner by means of compressed air or steam. The oil is burned in the form of a fine spray, and, without giving off any smoke or smell, lights up a radius of 200 yards around each burner. It has been used chiefly to light large spaces.

SWIFT OCEAN STEAMERS.—Lord Alfred S. Churchill, writing to *The Times*, with regard to the loss of the "Oregon," says: "The fact is that these great American liners travel at such a speed—viz., from 16 to 20 miles an hour—that on a dark night they come upon a strange vessel so rapidly that neither of them has much chance of avoiding a collision if not seen at at some distance off. My proposal is that these fast steamers should be fitted with electric search lights similar to those now in use on war ships, and that through the whole night these should be kept at work sweeping the horizon in front of and on either bow of the ship."

AN ELEVATED ELECTRIC RAILWAY VETOED.—A Bill passed by the City Councils of St. Louis has been vetoed by the Mayor, who says in his message: "An elevated railway, with electricity as the exclusive motive power, to be restricted to the carrying of passengers, would be a credit to the city and undoubtedly a benefit to the people at large; but the rights of property damaged by its construction should be securely protected, and the Bill should be so framed as to leave no question as to the exclusion of steam as a motor, or as to the possibility of its being converted into a freight road while in the hands of its projectors or their successors."

THE MAGNET IN MILLING.—One of the small things which will help the buhr miller is the use of the magnet. It is supposed by many that any device so simple and efficient as the magnet would be in every mill, but it is not. They make a separation which cannot be made by any other device. When the wire binders came into use some of the millers thought it would be necessary to exterminate them by refusing to buy wheat from the field in which they had been used. The magnets pacified them, and showed that there was more metal in other forms than wire to be taken out than the wire itself, even from the wheat on which the wire binders had been used. *Millstone.*

ELECTRIC TRAMWAY LOCOMOTION.—This is the title of a report in the *Leytonstone Express* of a private trial trip. From a scientific or a practical point of view this report is absolutely valueless. It simply tells that a car was propelled, the work being done by electric energy from seventy storage cells. Certain surmises are indulged in which give credit to fancies instead of facts. Why cannot we get independent examination by some such body as the Royal Agricultural Society? Surely cheap locomotion comes within the aims of the society. Let prizes be offered and trials made, then the results will be valuable; but surely to say a car was run up and down a line, and the batteries would continue working for so many more hours is a waste of time, ink, and paper.

UNDERGROUND WIRES.—We have consistently advocated the introduction of underground wires for telephonic purposes in large towns, and we believe we are correct in saying that the Bell Telephone Company of New York have practically adopted the Brooks system for underground wires, and no doubt we shall have to chronicle the laying of a large amount of the wires according to this system during the ensuing summer. The experience of our own telegraph department with these wires, if published, might be valuable. It may be remembered that Mr. Brooks was himself over in England in 1881 to superintend the extension of his system for the Post Office. The time that has elapsed since then must have been sufficient to give a fair trial to the system.

A NEW ELECTRIC LAMP.—The new incandescent lamp of Max Neuthel, which has been patented in Germany, dispenses with a vacuum. The filament consists of a mixture of conductors and non-conductors of electricity, being composed of magnesia and porcelain clay, saturated with platiniridium salts, and afterwards heated to incandescence in order to reduce the absorbed salts to the metallic state. The inventor supposes that the electric spark jumps from one particle to another, causing a heating action of the non-conducting substances, which are thus brought to incandescence and emit a strong steady light. The filaments are to be strengthened, when deemed necessary, by a covering of chrome, the melting point of which is still higher than that of platinum.

THE TELEPHONE.—Considering the period during which it has been in existence, the telephone has made more remarkable progress than any other invention. The number of instruments in use in the United States in 1877 was only 780, whereas in February, 1880, there were 60,800; in 1883, 249,700; in 1884, 307,010; and in February, 1885, 325,574. There are about 18,000 telephones in Canada, and only about 13,000 in Great Britain. The number of exchanges has grown from 100 in 1880 to 782 in 1885. In January last there were 137,223 miles of telephone wire in the United States. There are 5,186 persons constantly employed by the exchanges. More different patents have been issued on the telephone than in any other single line of invention in America. The total number for the last ten years is 1,521.

PROF. HENRY'S BIG MAGNET AND BATTERY.—Among the many valuable and historic pieces of apparatus about Yale college are several instruments which were invented and used by the late Prof. Henry in his experiments on electricity. In one of the laboratories of the school of science may be found his "big magnet," as it is called, mounted on a large frame, which, when charged with electricity by means of his "big battery" of one cell, was capable of lifting 3,300 pounds. He afterwards made one of nearly the same size and capacity for Yale, which has been in constant use there until within a few years, when it was laid aside, and is now preserved among other relics of the college. Prof. Henry's large magnetic globe, made partly of wood, constructed so as to show the electric current of the earth and the dipping of the needle, together with his galvanometers, coils, electro-magnets, and recorders, are of special interest and of peculiar historical value.—*Princetonian.*

FEMALE TELEGRAPH CLERKS.—If we are to judge by a correspondence that has recently been conducted in the *Standard*, the employment of young ladies as clerks in the Post Office is not an unmixed advantage to this branch of the public service. The writers, one and all, complain of the want of civility shown by the fair usurpers of the quill, not to speak of their utter disregard of the homely aphorism, "time is money." To a busy man certainly nothing can be more aggravating when he wants to despatch a telegram than to have to wait in a post office while the young ladies behind the counter (who ought to be alert to business) settle to their satisfaction the question of how a velvet dress should be trimmed, or what they ought to wear on Easter Monday. One correspondent suggests a remedy for this state of things—that there should be a male head in every office who would be responsible for discipline and order, and to whom the public might appeal in case of inattention or rudeness on the part of the female officials.

TELEPHONE EXPERIMENTS IN FRANCE.—The *Standard's* Paris correspondent states that new and interesting telephonic experiments have just taken place between Paris and Rheims, with the object of ascertaining whether persons provided with the telephone in Paris can correspond directly with telephone holders at Rheims. The distance separating Paris from Rheims is one hundred and seventy-two kilometres, but, including the length of the subterranean telephonic wires, the distance is two hundred and twenty kilometres. The lines serving for these experiments were two ordinary telegraphic wires, one of which was the Rheims wire, and the other the Berlin wire, which had been adapted to the public telephonic service organised between Paris and Rheims by means of M. Van Rysselberghe's anti-inductive system. This system permits of telegraphic and telephonic despatches being simultaneously transmitted by the same wires without the slightest confusion, so that while telephoning was going on between Paris and Rheims the same wires were traversed by telegraphic despatches exchanged between Paris, Rheims, and Berlin. All the experiments were perfectly successful.

THE EDINBURGH INTERNATIONAL EXHIBITION.—Satisfactory progress has been made in the preparations for the opening of the International Exhibition at Edinburgh. The building has cost £30,000. Applications for space have been numerous, 112,000ft. of which has been placed at the disposal of exhibitors, and that has all been taken up. The efforts made to get all the outside work accomplished before the opening day are likely to be successful. Groups, representing science and art, have been erected on high pedestals upon the flanking towers

Digitized by Google

of the main entrance. Variegated lamps for the electric light are being suspended throughout the grounds, and a good idea can now be formed of the general arrangement, which promises to be very effective. The shades for the incandescent lamps are coloured pink, blue, and gold, and these will be festooned between three rows of tall poles, round the band stand and elsewhere in the grounds, about 1,200 in all being placed outside. An electric railway has been laid down along the northern promenade. There are in all fourteen dynamos, with six boilers, and four vertical and two horizontal engines. Four of the boilers are for electric lighting, and two supply the steam for the machinery in motion.

THE EASTER MANŒUVRES.—We copy the following from *The Times*' account of the Volunteer operations in the advance upon Dover on Saturday last:—"The signallers were posted at every suitable spot, and were vigilant, smart, and untiring. It is, however, noteworthy that one of Moncrieff's signalling parties read the message of one of the enemy's signalling parties to Moncrieff's advantage. This is a lesson that ciphers not easily to be interpreted by an adversary should be used in war. In connection with signalling, I may mention that a system of communicating from Canterbury with Dover over the heads of the invaders was arranged by Major Allatt, who has long devoted himself to this important subject, to which more attention is paid on the Continent than in this country. At 8:30 this morning one of Major Allatt's pigeons arrived at Dover with a written message attached to it, stating that the enemy was advancing." We learn from another source that the Post Office riflemen, who took a conspicuous part in the turning movement on Lydden Hill, acquitted themselves in a manner which drew from their commanding officers the highest encomiums. A company of these men marched from Canterbury, and were foremost on the Lydden Hill without dropping a single man, notwithstanding the fact that they were in heavy marching order; whilst the casualties on the road in other Volunteer regiments, all of whom were lightly equipped, could be counted by hundreds.

DIFFERENCE BETWEEN POSITIVE AND NEGATIVE ELECTRICITY.—Dr. Wachter, of Vienna, has recently communicated to the Academy of Science in that town a paper, in which he attempts to prove that, contrary to the generally accepted belief, crediting positive and negative electricity with absolutely analogous properties differing only in sign, there are between them many points of diversity. He maintains that the properties of the two electricities are totally different, and these differences manifest themselves in regard to (1) equipotential surfaces, (2) direction of movement, (3) magnetic, (4) thermic, and (5) optic properties; also (6) in regard to the substances electrified. Dr. Wachter treats only of the first and second headings. He asserts that in conductors of great specific resistance the point where the potential has a mean value lies, not midway between the extreme ends of the conductor, but somewhat nearer the negative end. If equal quantities of positive and negative electricity accumulate respectively on two conductors of equal size, the potential, measured by means of an electrometer, has a greater value, irrespective of the sign, on the positive than on the negative conductor. The electric mill revolves in the direction of the flow of positive electricity, which proves that the movement of the molecules of air around a positive and negative point is different. The appearance of the discharge from such points is also different, indicating an inequality in the equipotential surfaces.

THE ELECTRIC LIGHT IN MINES.—We have been favoured by Mr T. Connolly with an advance proof of his paper read before the Manchester Geological Society, which we referred to in our last issue, pointing out that the *Athenæum* was—so far as its scientific information is concerned—behind the times. As we expected, Mr. Connolly's paper does not bear the construction put upon it by our contemporary. It may be interesting to give, briefly, Mr. Connolly's conclusions:—"Can we bring the electric light into practical use? Now, in carrying out this notion, I would like to combine, as far as I am concerned, the two systems—that is, the system of the conveyance of the electric current through all the main roads—everywhere as far as you can go up to the lamp station. In a large colliery, where it is so arranged, I think with every chance of safety, it could be carried up to that point, at all events, and even beyond; but assuming that it may be carried so far, let us see how it may be done in a practical manner. The difficulty has been suggested of providing against accidents by falls. I will suggest a means by which this may be overcome. We have a cable at the present time with an insulation which ten years ago could not have been got for four times the cost. It is the result of long study, the object being to get the cheapest and best cable which would enable us to embark on enterprises like these and yet have a return for the capital expended. In cases of falls of roof, say of several tons weight, or of a crush, it may be said that this cable would be entirely squeezed up. I venture to think that it would take a good deal more force than is ordinarily met with, unless it came in contact with jagged points, to crush through this insulation and render it incapable of retaining the current. . . . Now, supposing this system to be carried as far as the lamp station, would it be safe to carry it in-bye or no? In many cases I do not believe it would. Then we come back to the problem which is being fought out—the safety lamp of the miner;" which the author said was as yet not settled.

BLASTING OPERATION AT THE ROYAL ALBERT DOCK.—The wall which bounded the tidal basin of this dock on its north-east side, and which it was found necessary to remove to provide a new entrance suitable for the increased draught and dimensions of ocean liners, was successfully blown up last week by gelatine dynamite, fired by electricity. The total length of the wall was 520ft., and the estimated weight of material, flint, and pebble concrete 7,850 tons. The electrical wiring for the simultaneous discharge of the shots was carried out by Messrs. Siemens, who have the lighting of the docks, the plan of operations having been submitted by the Dock Company to Sir Frederick Abel. One of the alternating machines used for shed lighting, and in its ordinary working giving off a current of 48 amperes at 600 volts, was coupled up in series to develop a high tension current of 24 amperes at 1,200 volts, to suit it for firing the high tension Abel fuzes employed on the occasion, this being the first time that such a large number of this class of chemical fuses have been used, platinum wire or low tension fuses being usually adopted for this kind of operations. Two well insulated main leads of copper wire were brought from the ordinary electric lighting station beyond the Galleons Basin, and were carried along the rear of the wall. Two additional mains were also carried from the machine and united with the first mains about the middle and at the end of the wall, so that if any damage or defect occurred at any point in the transmission of the current it would have independent means of percolating the network system of branches which were taken off from the mains to the fuses. The transmitting mains were tapped at the firing station, erected near the bridge at the western extremity of the basin by a tumbler-switch, by a blow upon which the electrical current could be instantaneously put into circuit. The total length of branch wires was over six miles, and the total quan-

Digitized by Google

tity of gelatine dynamite employed was stated to be 2,860lb. Six feet of the wall was above the level of the water in the basin.

THE WAR OF CABLE RATES.—It will be seen by the following table, says the *Daily News*, that the four united companies have an aggregate capital of nearly £12,700,000, and they have also large reserves in hand; while the Mackay-Bennett Company has little or no visible reserve in hand. For the sake of showing the position we add the percentages of gross receipts agreed on by the four older companies in the pool, together with a calculation, based on the traffic receipts of the Anglo-American Company for last half year, of the annual revenues respectively obtained by the combined companies when working at the rate of 1s. 8d. per word. This rate, although high enough for the commercial community, has not satisfied the combined companies, and they are therefore attempting to "freeze out" the non-conforming company by reducing the rates to the basis of 6d. per word :—

No. of Cables.	Company.	Capital.	Proportion in Pool.	Being (at 1s. 8d. per word) yearly
4	Anglo-American	£7,000,000	49 p.c.	£280,000
2	American Tel. and Cable (guar. by West. Union).	2,800,000	22½ ,,	130,000
1	Direct U.S. Cable	1,214,000	16¼ ,,	92,000
1	Co. Francaise du Tel.	1,680,000	12¼ ,,	70,000
8	Totals	£12,694,000	100 ,,	£572,000

Early last year the Commercial Cable Company, the result of a partnership between Mr. Mackay, the capitalist, and Mr. Jas. Gordon Bennett, the newspaper owner, opened its wires to the public at a standard charge of 1s. 8d. per word. What Mr. Mackay's motives might have been over and above the general dollar-making motive which pushes on most American enterprises it is useless to guess about. He saw a monopoly, doubtless disliked it, and attempted to break it down. Profiting by the cheapness, or what then appeared to be cheapness, of copper and other material, he made two cables, understood to have cost barely £700,000 each. This is less than half the capital per cable of the Anglo-American Company, which owns four cables, and has a stock of £7,000,000 altogether. In addition to the advantage of a small prime cost, the new company had that of an independent entry into New York and other Atlantic ports. But this very independence brought upon it an enemy by land as well as by sea. The Western Union Telegraph Company has a virtual monopoly of the inland telegraphic system in the United States; and inasmuch as all the ocean cables are dependent on its services for the transmission of their messages to and from the interior, they are naturally disposed to make common cause against an intruder, like the Mackay line, which breaks into the fringe of the land line monopoly. The following circular, issued by the Commercial Cable Company, was published in yesterday's papers :—"We beg to inform you that on and after the 5th prox., until further notice, the rate for telegrams by this company's cables to all points in the United States of America, Canada, &c., will be reduced to 1s. per word, The 'pooled' Atlantic cable companies, consisting of the Anglo-American, Direct United States, French, and Western Union, have made strenuous efforts to induce this company to raise the tariff to 2s. 6d.; and as we have refused to accede to their wishes, they announce a sixpenny rate. It is known full well that this rate would result in a serious loss to all the companies, but the 'pooled' companies think by adopting this extreme measure the Commercial Cable Company will be forced to come to terms, and raise the price to the figure desired. The Commercial Cable Company commenced business at 1s. 8d. per word, being a reduction of 20 per cent. on the then existing charge; and the amount of patronage we have received proves that the rate is a popular one. It was the intention of the Commercial Cable Company to regard 40 cents as their maximum, gradually reducing the price as opportunity offered. The earnest wish of this company is to maintain the 1s. 8d. rate, and to this end we ask the public to make a temporary sacrifice by supporting us at 1s, on the assurance that if we are vigorously backed up now the tariff shall return to the original figure, viz., 1s. 8d." On this the *Standard* observes that "they may be quite sure the public will do nothing of the sort. It would not have done so even had the Mackay-Bennett Company been popular, because charity is not business. But this private concern has done nothing to enlist popular sympathies on this side. Its ways are said to be American, and, rightly or wrongly, its rivals accuse it of not sticking to the published tariff of 1s. 8d. per word. Rebates more or less heavy were, it is alleged, granted to large customers—hence, in part, the declaration of war. However this may be, if Messrs. Mackay and Bennett had bravely prepared for a good stand up fight by lowering their tariff to sixpence per word, or, if possible, less, and sticking to their guns, they would have had much more popular support and sympathy than they can now expect to receive."

PERSIA.—The first number of a new contemporary, the *Indian Engineer*, contains a contribution from Shiraz which shows most clearly that a telegrapher's position in Persia is not all rose leaves. Probably most people in England have an idea that Persia is never troubled with snow storms, but the opposite is the case. The correspondent says that on Christmas Eve he found it snowing heavily, and that it continued snowing nearly all day. About noon the wires on both sides of the station were interrupted. With great difficulty he managed to get home on being relieved in the evening at 7 o'clock, the snow having ceased falling at 4 o'clock. Subsequently it was found that the iron poles were down in all directions. The staff then commenced the repairs, and all that could be spared were out working on the line. The following is taken verbatim from the letter, and shows better than any words of ours the difficulties encountered by the profession in far-off lands :—"They had frightful weather, and at Khonah Khorah, where there is only a caravanserai and a chaperkhanah, they could get nothing to eat, and were nearly starved for two days. They got the International wire up, and Hamilton returned to Dehbeed; Aganoor to Abadeh. Hamilton on arriving at Dehbeed found that all wires were interrupted towards Shiraz, so he went out again (after the most trying weather and hard work he had in the pass between Dehbeed and Abadeh) repairing the line. He got to Moorghab after two or three days' hard work (Moorghab is 32 miles this side of Dehbeed). At Moorghab he felt seedy. Gifford, from Koomeshah Station, who had come to help Hamilton, arrived at Moorghab, and found Hamilton suffering from great pain in his stomach, and inflammation of the whole body. Gifford at once sent a chapar to Swand with a message for the doctor (there being no telegraphic communication then). On the doctor receiving the telegram from Swand he prescribed and left Shiraz chapar with medicines, &c., to see poor Hamilton, but before he reached Moorghab poor Hamilton had died (on 14th January). The poor fellow had suffered most agonising pain until he expired. He died from exposure to the severe weather and want of proper food. All the people in this telegraph department feel his loss. He came to his end facing such severe weather and doing his duty, and sacrificing himself in the performance of the same."

ON THE USE OF THE BRIDGE AS AN INDUCTION BALANCE.

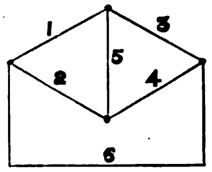
BY OLIVER HEAVISIDE.

In connection with a paper "On Electromagnets, &c.," that I wrote about six years ago, to be found in the *Journal* of the Society of Telegraph-Engineers and Electricians, which paper dealt mainly with the question of the influence of the electromagnetic induction of the lines and instruments on the magnitude of the signalling currents, an influence which is of the greatest importance on short lines, and which (of the instruments) is, even on long lines, where electrostatic induction is prominent, of importance as a retarding factor, I made a great many experiments on self-induction, amongst which were measurements of the inductances of various telegraph instruments, with a view to ascertaining their practical values, and also the multiplying powers of the iron cores. It was my intention to write a supplementary paper giving the results and also further investigations; but, having got involved, in the course of the experiments, in the difficult subject of magnetic inductivity, it was postponed, and then dropped out of mind.

I used, first of all, the bridge and condenser method described by Maxwell, with reversals, and a telephone for current indicator. This was to get results at once, or by simple calculations, in electro-magnetic units. Next, I discarded the condenser, and used the simple bridge, balancing coils against standard coils. Thirdly, I have used a differential telephone with the same object, in a similar manner. The two last are very sensitive methods, and the verifications of the theory of induction in linear conductors that I have made by them are numerous.

The whole of this journal would be required to give anything like a full investigation of the various ways of using the bridge as an induction balance. I can, therefore, only touch lightly on the subject of exact balances, especially as I have to remark upon faulty methods, approximate balances, and absolutely false balances. Prof. Hughes's balance is sometimes fairly approximate, sometimes quite false.

Put a telephone in the branch 5, battery and interrupter in 6. Then, r standing for resistance, l for inductance (coefficient



of self-induction), and x for l/r, the time constant of a branch, the conditions of a true and perfect balance, however the impressed force in 6 vary, are three in number, namely,

$$r_1 r_4 = r_2 r_3 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$x_1 + x_4 = x_2 + x_3 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$l_1 l_4 = l_2 l_3 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Their interpretations are as follows:—If the first condition is fulfilled there will be no final current in 5 when a steady impressed force is put in 6. This is the condition for a true resistance balance.

If, in addition to this, the second condition be also satisfied, the integral extra current in 5 on making or breaking 6 is zero, besides the steady current being zero. (1) and (2) together therefore give an approximate induction balance with a true resistance balance.

If, in addition to (1) and (2), the third condition is satisfied, the extra current is zero at every moment during the transient state, and the balance is exact, however the impressed force in 6 vary.

Practically, take

$$r_1 = r_2, \quad \text{and} \quad l_1 = l_2, \quad . \quad . \quad . \quad . \quad (4)$$

that is, let branches 1 and 2 be of equal resistance and inductance. Then the second and third conditions become identical; and, to get perfect balances, we need only make

$$r_3 = r_4, \quad \text{and} \quad l_3 = l_4. \quad . \quad . \quad . \quad . \quad (5)$$

This is the method I have generally used, reducing the three conditions to two, whilst preserving exactness. It is also the simplest method. The mutual induction, if any, of 1 and 2, or of 3 and 4, does not influence the balance when this ratio of equality, $r_1 = r_2$, is employed (whether $l_1 = l_2$ or not). So branches 1 and 2 may consist of two similar wires wound together on the same bobbin to keep their temperatures equal.

The sensitiveness of the telephone has been greatly exaggerated. Altogether apart from the question of referring the sensitiveness to the human ear rather than to the telephone, it is certainly, under ordinary circumstances, often unable to appreciate the differences of the second order, which vanish when the third condition is satisfied. Thus (1) and (2) satisfied, but with (3) unsatisfied, will give silence. Take, for instance, $r_1 = r_2$ and $r_3 = r_4$, but l_1 different from l_2 and l_3 from l_4, then silence is given by

$$(l_1 - l_2)/r_1 = (l_3 - l_4)/r_3 \quad . \quad . \quad . \quad . \quad (6)$$

that is, by making the differences of the inductances on the two sides of 5 proportional to the resistances. We can therefore get silence by varying the inductance of any one or more of the four branches 1, 2, 3, 4, to suit equation (6). It is certain that we do get silence this way, but it does not follow that silence is given by *exactly* satisfying (6), (and (1) of course), because it is only a balance of integral extra currents, and other balances of this kind are certainly quite false sometimes. To avoid any doubt, it is of course best to keep to the legitimate and simpler previously-described method.

There are some other ways of using the bridge as an induction balance in an exact manner, but they are less practically useful than theoretically interesting. Pass, therefore, to other approximate, and to false balances. Suppose we start with a true balance, and then upset it by increasing the inductance of the branch 4. It is clear that we should never alter the already truly established resistance balance. Now, besides by the exact ways, we can get approximate silence by allowing mutual induction between 5 and any of the other five branches, or between 6 and any of the other five branches, that is nine ways, not counting combinations. (Put test coils in 5 and 6 with long leading wires, so that they may be carried about from one branch to another.) These approximate balances are all of the integral extra current only, and therefore imperfect, however nearly there may be silence. But the silences are of very different values.

I find, using fine wire coils, that mutual induction between 6 and 4 or between 6 and 3 gives silence (to my ear) with the true resistance balance, just like the approximate balance of equation (6) in which no mutual induction is allowed.

These are only two out of the nine ways. All the rest are bad. If the difference in the inductance of 3 and 4 be small, there is very nearly silence on using any of the other seven ways; but, the larger this difference is made, the louder becomes the "silence," and sometimes it is even a very loud noise, quite comparable to the original sound that was to be destroyed, even when the combinations 6 and 4 or 6 and 3, and the formerly-mentioned method give a silence that can be felt, with the true resistance balance.

It is certainly a rather remarkable thing that the one method out of these seven faulty ways which gave the very loudest sound was the 5 and 6 combination, which is Professor Hughes's method. I do not say that it is always the worst, although it was markedly so in my experiments to test the trustworthiness of the method. And sometimes it is quite fair. In fact, when the sound to be destroyed is itself weak, all the seven faulty methods are apparently alike, nearly true. But when we exaggerate the inequality of inductance between 3 and 4, whilst the 6 to 4 and 6 to 3 combinations keep good, the others get rapidly worse, and differences appear between them.

I found that by increasing the resistance of the branch whose inductance was the smaller, the sound was diminished greatly, *i.e.*, in the seven faulty methods. The coil of greater inductance had apparently the higher resistance. That is, with a false resistance balance we may approximate to silence. Such a balance is damned for scientific purposes.

Digitized by Google

Although mutual induction between 6 and 4 or 6 and 3 gave silence, with true resistance balances, the experiments were not sufficiently extended to prove their general trustworthiness. There is, however, some reason to be given for their superiority. For, since the disturbance in the telephone arises from the inequality of the momenta of the currents in the branches 3 and 4, and of the electric impulses arising in them when contact is broken in branch 6 (considering the break only for simplicity), we go nearest to the root of the evil by generating an additional impulse in 3 or 4 themselves from the battery branch, of the right amount.

The following is an outline of the theory of these approximate balances. Let $r_1 r_4 = r_2 r_3$ first; so that, C standing for current, we have, in the steady state

$$C_1 = C_3 = C_4 r_4/r_3\,; \qquad C_2 = C_4\,; \qquad C_6 = C_4(1 + r_4/r_3)\,. \quad . \quad (7)$$

The momentum of the current in branch 1 is $l_1 C_1$, that in 2 is $l_2 C_2$, and so on. Consider the break, and the integral extra current that then arises from $l_1 C_1$. It is

$$l_1 C_1 \div \{r_1 + r_2 + r_5(r_3 + r_4)/(r_3 + r_4 + r_5)\},$$

and $(r_3 + r_4)/(r_3 + r_4 + r_5)$ is the fraction of this that goes through 5; so that the integral current in 5 due to $l_1 C_1$ is

$$l_1 C_1 (r_3 + r_4) \div \{(r_1 + r_2)(r_3 + r_4) + r_5(r_1 + r_2 + r_3 + r_4)\}$$

or

$$C_4 r_4 x_1 \div \{r_3 + r_4 + r_5 + r_3 r_5/r_1\}$$

by making use of equations (1) and (7).

Treat the others similarly. The total extra current in 5 is

$$r_4 C_4 (x_1 + x_4 - x_2 - x_3) \div \{r_3 + r_4 + r_5 + r_3 r_5/r_1\} \quad . \quad . \quad (8)$$

without any mutual induction. So

$$x_1 + x_4 = x_2 + x_3$$

gives approximate balance. This was mentioned before, and becomes an exact balance with makes and breaks when a ratio of equality is taken.

Now let there be mutual induction between 6 and 4, 5 and 4, and 5 and 6, the mutual inductances being M_{64}, &c. Treating these similarly to before, we shall find the total extra current in 5 on the break taking place to be

$$\{r_4(x_1 + x_4 - x_2 - x_3) + M_{64}(1 + r_4/r_3) + M_{54}(1 + r_3/r_1)$$
$$+ M_{56}(1 + r_3/r_1)(1 + r_4/r_3)\}C_4 \div (r_3 + r_4 + r_5 + r_3 r_5/r_1)\,. \quad (9)$$

The theory of the make leads to the same result—that is, as regards the *integral* extra current. Otherwise they are different. So, using M_{56} (Hughes's method) the zero integral current is when

$$r_4\,(x_1 + x_4 - x_2 - x_3) + M_{56}\,(1 + r_3/r_1)\,(1 + r_4/r_3) = 0 \quad (10)$$

Using M_{45} we have

$$r_4\,(x_1 + x_4 - x_2 - x_3) + M_{45}\,(1 + r_3/r_1) = 0\,. \quad . \quad (11)$$

Using M_{64} we have

$$r_4\,(x_1 + x_4 - x_2 - x_3) + M_{64}\,(1 + r_4/r_3) = 0 \quad . \quad (12)$$

Practically employ a ratio of equality $r_1 = r_2$, $l_1 = l_2$—that is, make branches 1 and 2 equal fixtures. Then these three equations become

$$l_4 - l_3 + 2M_{56}(1 + r_3/r_1) = 0, \quad . \quad . \quad . \quad (10a)$$
$$l_4 - l_3 + M_{54}\,(1 + r_3/r_1) = 0, \quad . \quad . \quad . \quad (11a)$$
$$l_4 - l_3 + 2M_{46} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (12a)$$

Thus the M_{46} system has the simplest formula, as well as being practically perfect. It is the same with M_{63}. Either of these must equal half the difference of the inductances of 3 and 4.

As (10*a*), or, more generally (10) contains resistances, we cannot get any definite results from Prof. Hughes's numbers without a knowledge of the resistances concerned. Note, also, that (10) and (11) are faulty balances; to improve them, destroy the resistance balance; of course then the formula will change, and is likely to become very complex.

It will be understood that when I speak of false resistance balances in this paper I do not in any way refer to the thick wire phenomenon, mentioned in my letter on p. 471, April 23, which, from its very nature, requires the resistance balance to be upset, or be different from what it would be if the wire were thin, but of the same real resistance. The resistance balance must be upset in a perfect arrangement. Nor can there be a true balance got, but only an approximate one, unless a similar thick wire be employed to produce balance.

What I refer to here is the upsetting of the true resistance balance when there is no perceptible departure whatever from the linear theory. The two effects may be mixed.

To use the bridge to speedily and accurately measure the inductance of a coil, we should have a set of proper standard coils, of known inductance and resistance, together with a coil of variable inductance, *i.e.*, two coils in sequence, one of which can be turned round, so as to vary the inductance from a minimum to a maximum. (The scale of this variable coil could be calibrated by (12*a*), first taking care that the resistance balance did not require to be upset.) This set of coils, in or out of circuit according to plugs, to form say branch 3, the coil to be measured to be in branch 4. Ratio of equality. Branches 1 and 2 equal. Of course inductionless, or practically inductionless resistances are also required, to get and keep the resistance balance.

The only step to this I have made (this was some years ago) in my experiments, which, of course, were mere dabbling, was to have a number of little equal unit coils, and two or three multiples; and get exact balance by allowing induction between two little ones, with no exact measurement of the fraction of a unit.

So long as we keep to coils we can swamp all the irregularities due to leading wires, &c., or easily neutralise them, and therefore easily obtain considerable accuracy. With short wires, however, it is a different matter. The inductance of a circuit is a definite quantity. So is the mutual inductance of two circuits. Also, when coils are connected together, each forms so nearly a closed circuit that it can be taken as such, so that we can add and subtract inductances, and localise them definitely as belonging to this or that part of a circuit. But this simplicity is, to a great extent, lost when we deal with short wires, unless they are bent round so as to make nearly closed circuits. We cannot fix the inductance of a straight wire, taken by itself. It has no meaning, strictly speaking. The return current has to be considered. Balances can always be got, but as regards the interpretation, that will depend upon the configuration of the apparatus.

Speaking with diffidence, having little experience with short wires, I should recommend 1 and 2 to be two equal wires, of any convenient length, twisted together, joined at one end, of course slightly separated at the other, where they join the telephone wires, also twisted. The exact arrangement of 3 and 4 will depend on circumstances. But always use a long wire rather than a short one (experimental wire). If this is in branch 4, let branch 3 consist of the standard coils (of appropriate size), and adjust *them*, inserting if necessary, coils in series with 4 also. Of course I regard the matter from the point of view of getting easily interpretable results.

The exact balance (1), (2), (3) above is quite special. If the branches 1 and 3 consist of any combination of conductors and condensers, with induction in masses of metal allowed, and branches 2 and 4 consist of an exactly equal combination, in every respect, there will never be any current in 5 due to impressed force in 6. And more generally $2 + 4$ may be only a copy of $1 + 3$, on a reduced scale, so to speak.

P.S.—April 27, 1886. The great exactness with which, when a ratio of equality is used, the M_{64} and M_{63} methods conform to the true resistance balance, as above mentioned, together with the almost persistent departure of the M_{65} (Hughes's) method from the true resistance balance, led me to suspect that, as in the use of the simple Bridge method, with no mutual induction, the three conditions of a true balance are reduced to two by a ratio of equality, the same thing happens in the M_{64} and M_{63} methods, but not in the M_{65}. This I have verified.

In Hughes's system, the three conditions are

$$r_1 r_4 = r_2 r_3, \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$
$$r_4(x_1 + x_4 - x_2 - x_3) + M_{56}(1 + r_3/r_1)(1 + r_4/r_3) = 0, \quad . \quad (14)$$
$$l_1 l_4 - l_2 l_3 + M_{56}(l_1 + l_2 + l_3 + l_4) = 0. \quad . \quad . \quad (15)$$

Now take $l_1 = l_2$, $r_1 = r_2$, $r_3 = r_4$; then the second and third are equivalent to

$$l_4 - l_3 + 2M(1 + r_3/r_1) = 0, \qquad 2x_1/x_3 = 1 + l_4/l_3.$$

Digitized by Google

The second of these is a *special relation* that must hold before the first is true. Hence the sound with a true resistance balance, and the necessity of a false balance to get rid of it.

But in the M_{64} method the conditions are

$$r_1 r_4 = r_2 r_3, \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

$$r_4(x_1 + x_4 - x_2 - x_3) + M_{64}(1 + r_2/r_1) = 0, \quad . \quad (17)$$

$$l_1 l_4 - l_2 l_3 + M_{64}(l_1 + l_2) = 0. \quad . \quad . \quad . \quad (18)$$

Take $l_1 = l_2$, $r_1 = r_2$, $r_3 = r_4$, as before, and *now* the second and third conditions become identical, viz.,

$$l_4 - l_3 + 2M_{64} = 0,$$

agreeing with the previously obtained equation (12*a*).

Thus, whilst Hughes's method is inaccurate, sometimes greatly so, we may employ the M_{64} and M_{63} methods without any hesitation, provided a ratio of equality be kept to. They will be as accurate as the simple bridge method, and the choice of the methods will be purely a matter of convenience.

I have verified experimentally that the Hughes system requires a false resistance balance when, instead of coils, short wires are used, the branch of greater inductance having apparently the greater resistance. I have also verified that this effect is mixed with the thick wire effect, which last is completely isolated by using the proper M_{64} method or the simple bridge. Its magnitude can now be exactly measured, free from the errors of a faulty method. That is, it can be estimated for any particular speed of intermittences or reversals, for it is not a constant effect. Balance a very thin against a very thick wire, so that the effect occurs only on *one* side.

CARLETON'S FIRE-DAMP INDICATOR.

This apparatus for indicating fire-damp, says *The Engineering and Mining Journal*, was invented by Henry Guy Carleton, of New York. It consists, essentially, of one or more indicating balances to be permanently placed in a goaf or drift of the mine, and a registering balance to be used by the observer in the testing room, connected by well insulated wires. Each balance holds in equilibrium a thin glass bulb of about 300 cubic inches' capacity, hermetically sealed. They are counterbalanced at the same moment by the weights W and W′, respectively, as shown in the accompanying illustrations, and hence will be equally affected by future variations in the atmospheric pressure. Attached to the vertical arm or pointer H of each balance is a soft iron needle, *d*, gilded to prevent rusting. Its ends plunge freely into helices of insulated wire, *a* and *b*.

The helices on both instruments are exactly of the same size and electrical resistance, and of sufficient internal diameter to exert but feeble influence on the needles with an ordinary current. The right hand helix of balance No. 1 is connected with the right hand helix of balance No. 2, and is supplied at will from the battery I I with current whose strength can be lessened gradually and delicately by resistances thrown into the circuit by the rheostat, enabling the magnetic force of the helices to be regulated to a nicety. The left hand helices are similarly connected through battery I and rheostat.

The vertical arm H of balance No. 2 has a platinum tip capable of electrical contact with the insulated screw *c*. Connection from binding post 4 to the vertical arm is made by means of the mercury cup *m*, into which a wire from the beam is dipped. By contact between H and *c*, the relay in the observing room is kept closed. Breaking contact opens the relay, whose back-stroke shunts the local circuit on the bell, ringing it continuously. The resistance coil *g*, connected with binding-posts 3 and 4, prevents a spark passing when H and *c* break. The case surrounding balance No. 2 is of marble or unglazed tiling, excluding air currents and dust, yet admitting gases by diffusion. Chloride of calcium, in the holder D′, keeps the interior free from moisture. The whole is protected from injury by a perforated iron case, as shown. Once placed in its position in the mine, its temperature will be constant.

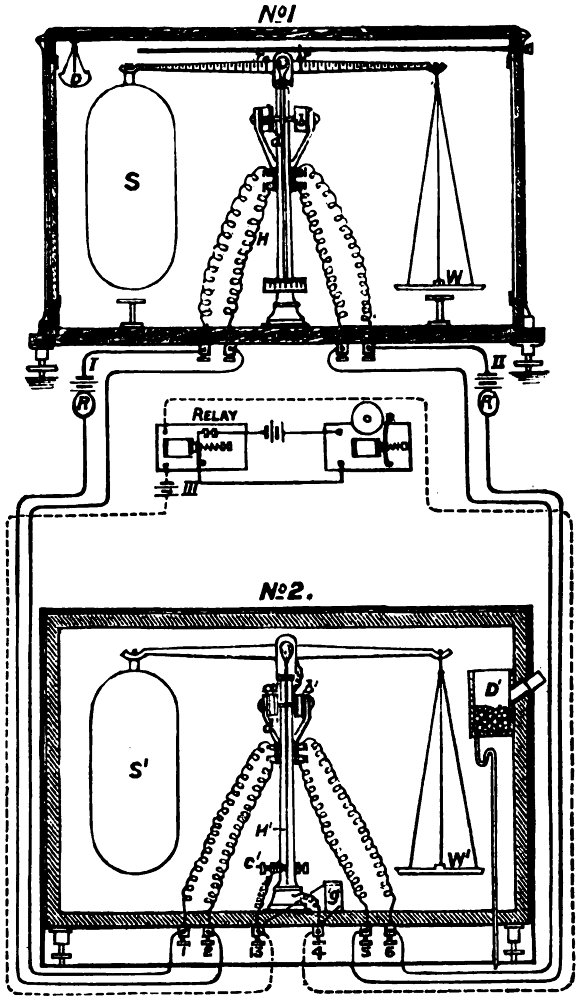
Balance No. 1, in the observing room, is provided with two riders, moved along the graduated beam, as shown. If more delicate readings are desired, additional riders of less weight may be also employed, a separate way being provided on the beam. Balance No. 1 is encased, dried by chloride of calcium, and placed in a room artificially maintained at constant temperature by means well known.

By this arrangement it will be seen :—

1st. That as the two bulbs S S′ are equal in bulk, and balanced at the same moment, they will be affected equally in weight by an increase or decrease in atmospheric pressure.

2nd. That the right hand helix of each instrument will exert the same amount of force on its responsive needle, both being supplied with current from the same battery, and that the same rule will apply to the left-hand helices.

3rd. That as each instrument is kept in an atmosphere of constant temperature and equal hygrometric condition, it will only be sensitive to a change in the pressure of said atmosphere or a change in its atomic weight.



Carleton's Fire-Damp Indicator.

Both instruments are balanced at the same moment by their weights W W′ respectively. The case of balance No. 2 is then filled with pure fire-damp at normal pressure, obtained from a "blower" in the mine. (This will obviate the necessity of correcting for that percentage of carbonic acid always associated with marsh gas in fire-damp, as would be necessary if pure marsh gas were used.)

Care, of course, is taken to keep a stream of the gas flowing in, to counteract the diffusion of air through the case. Bulb S′ will now sink, its increase in weight being about 39 grains, H will break contact with *c*, and the bell rings The observer now switches on battery I, which applies a force of, say, 45 grains, through helix *a′* to the needle attached to the vertical arm of balance No. 2. This more than compensates for the increase in weight, H is brought back to *c*, and the bell ceases to ring. The observer now throws in small resistances until H breaks again, and thus finally satisfies himself that the amount of force applied through helix *a′* of the distant instrument is

Digitized by Google

just enough to balance it and no more. Now, as this amount of force is also exerted by helix *a* upon the needle of balance No. 1, its equilibrium is disturbed. Rider *r* is therefore shifted until equilibrium is restored. The position of this rider equals the force applied through helix *a*; equals the force applied through the helix of the distant instrument, No. 2; and necessarily equals the increased weight of the bulb S′ in pure fire-damp. From this point, therefore, to zero, the observer graduates his beam into hundredths and minor subdivisions. The graduation is then made in similar manner for carbonic acid, employing rider *r′* and battery I I. In practice, these graduations would be made before the instruments were placed in position, allowances being made for the depth and increased temperatures to which each balance is to go.

Thus adjusted, the instrument will act under the conditions named as follows:—

1. *Rising Barometer and no "Fire-Damp."* 2. *Falling Barometer and no "Fire-Damp."* 3. *Rising Barometer and "Fire-Damp."* 4. *Falling Barometer and "Fire Damp."*

Notes.—1. The percentage of carbonic acid exhaled from coal usually runs from 0·30 to 2·1 per cent. in fire-damp, varying in different mines, but practically constant in any one. There may be a sudden increase by an explosion, but ventilation would soon restore the normal condition. The quantity produced by the lamps and men is insignificant, since the ventilation necessary to keep the mine free from fire-damp sweeps away the carbonic acid from this source as fast as formed.

2. Should it be desirable to test for marsh gas only, balance 2 may be surrounded by an air-tight case, provided with a tube opened or shut at will by a mercury valve operated by an electromagnet controlled from the observing station. This tube would be opened for, say, five minutes. During that time the external gases would diffuse perfectly through the tube into the case, but both moisture and carbonic acid would be immediately absorbed by caustic potassa placed in D′. The tube would then be closed, and measurements taken, pure marsh gas being the standard. These tests would be made as often as desired, the observer having full control of the valves on all the instruments and operating all on one circuit.

3. While a separate circuit is shown for the right-hand or left-hand helices, it is practicable, by a simple device arranged by the inventor, to operate either helix at will from the observing station, and yet use but a single circuit.

4. With bulbs of 300 cubic inches capacity, a balance weighing to $\frac{1}{10}$th of a grain will give the percentage of marsh gas to $\frac{1}{3}$rd of 1 per cent. The bulbs weigh six ounces. This weight may be lessened 86 grains by filling them with pure hydrogen. A reading to $\frac{1}{3}$rd of 1 per cent. is close enough in practice.

5. The instrument is especially designed for use in goaves, where large accumulations of the gas are more liable to form. A decrease in atmospheric pressure forces it out in the workings, where it may be fired by a shot, a defective lamp, or other causes. It having been settled that the explosions supposed to be wholly due to coal dust depend on marsh gas in conjunction with the dust, the necessity for close watch upon even small percentages is obvious.

6. As marsh gas spreads with tolerable rapidity, one instrument will guard a considerable area, especially in a goaf where ventilation is neglected.

DYNAMO-ELECTRIC MACHINES.*

BY JOHN HOPKINSON, D.SC., F.R.S., AND EDWARD HOPKINSON, D.SC.

Omitting the inductive effects of the current in the armature itself, all the properties of a dynamo machine are most conveniently deduced from a statement of the relation between the magnetic field and the magnetising force required to produce that field. This relation given, it is easy to deduce what the result will be in all employments of the machine, also the result of varying the winding of the machine in armature or magnets. The magnetic field may be expressed algebraically as a function of the magnetising force, or more conveniently by a curve (*Proceedings* of the Institution of Mechanical Engineers, April, 1879, p. 246). Amongst the empirical formulæ which have been proposed to express the electromotive force of dynamo machines in terms of the currents around the magnets, we may mention that known as Fröhlich's, where $E = \frac{ac}{1 + bc}$, E being the electromotive force of the machine at a given speed, *c* the exciting current, and *a* and *b* constants. For some machines this hyberbola is said to express observed results fairly accurately. In our experience it does not sufficiently approximate to a straight line in the part of the curve near the origin, and gives too high results for large values of *c*.

One purpose of the present investigation is to give an approximately complete construction of the characteristic curve of a dynamo of given form from the ordinary laws of electro-magnetism and the known properties of iron. Let *n* be the number of convolutions on the magnets, *c* the current round the magnets, l_1 the mean length of the lines of force in the iron of the armature, A_1 the area of section of iron in the armature, l_2 the distance from iron of armature to iron of pole pieces, A_2 the area of the magnetic field in which the wires move corrected for its extension round the edge of the pole pieces, l_3 the total length of the magnet cores, A_3 the area of the magnet cores, l_4 the mean length of lines of force in the yoke connecting the magnet limbs in machines of the type on which we have principally experimented, A_4 the area of section of the yoke, l_5 the mean length of the lines of force in each pole piece, A_5 the mean area of section of pole piece, I the total induction through the armature, when no current passes in the armature, and νI the total induction in the magnet cores; and, finally, let the relation between the magnetic force (α) and induction (a) (*vide* Thomson, "Electrostatics and Magnetism," p. 397, and Maxwell, "Treatise on Electricity and Magnetism," Vol. II., p. 24) be represented by the equation $\alpha = f(a)$, then the characteristic curve is—

$$4\pi nc = l_1 f\left(\frac{I}{A_1}\right) + 2l_2 \frac{I}{A_2} + l_3 f\left(\frac{\nu I}{A_3}\right) + l_4 f\left(\frac{\nu I}{A_4}\right) + 2l_5 f\left(\frac{I_5}{A_5}\right).$$

If the relation between α and a be given in the form of a curve, this formula indicates at once a perfectly simple graphical construction for the characteristic. Taking the curve of magnetisation determined by one of us for wrought iron, and constructing a characteristic in this way, we have obtained a theoretical curve which agrees over a long range with the actual results of observation on a dynamo machine more closely than any empirical formula with which we are acquainted.

To determine ν, a wire was taken once round the middle of one magnet and connected to a ballistic galvanometer; a known current was then either suddenly passed round the magnets or short-circuited, the elongation of the galvanometer being noted. A similar observation was made with the same current, the galvanometer being connected to a single convolution of the armature in the plane of commutation. The ratio of the two elongations is the value of ν.

The distribution of the waste field $(\nu - 1)$ I was roughly ascertained in a similar method.

The currents in the fixed coils round the magnets are not the only magnetising forces applied in a dynamo machine. The currents in the moving coils of the armature have also their effect upon the resultant field. In well-constructed machines the effect of the latter is reduced to a minimum, but it can be by no means neglected. This introduces a second independent variable, viz., C, the current in the armature. The effect of the current in the armature depends upon the lead given to the brushes. Denote this by λ, which we may also regard as an independent variable, as it is subject to arbitrary adjustment.

If $I = F(4\pi nc)$ be the characteristic curve when no current passes through the armature, then

$$I + \frac{\nu - 1}{\nu} 4\lambda m C \frac{A_2}{l_2} = F\left(4\pi nc - \frac{4\lambda m C}{\nu}\right),$$

where *m* is the number of convolutions in the armature. Here

* Abstract of a Paper read before the Royal Society.

Digitized by Google

we omit the comparatively unimportant portion of the magnetic force in the core of the armature and the pole pieces. From this formula it is not difficult to deduce a geometrical construction for the characteristic surface (*vide* "Practical Applications of Electricity," lectures delivered at the Institute of Civil Engineers, 1882-83, p. 98). The equation may be thus expressed in words, if λ be such that the coils at commutation embrace the whole or nearly the whole induction. The effect of the current in the armature upon the difference of potential between the brushes of any machine is the same as that of an addition to the resistance of the armature proportional to the lead of the brushes, and to the ratio of the waste field to the total field, combined with that of taking the main current $\frac{m\lambda}{\nu\pi}$ times round the magnets in a direction opposite to the current c. Many consequences can be deduced, of which we may notice the following :—In a series wound dynamo C is equal to c, and if c be increased beyond a certain point, I must attain a maximum and then diminish; this has been frequently observed. We now see that it depends upon the existence of a waste field. Secondly, let the coils of the magnets be entirely disconnected, and let λ be the negative; if the armature be short circuited through a small resistance and be run at a sufficient speed, a large current may be produced in the armature. This latter deduction we have verified by direct experiment.

The efficiency of the type of dynamo machine upon which the experiments before indicated have been made has been accurately determined by the device of coupling two similar machines, both mechanically and electrically, so that one should act as a generator of electricity, driving the other electrically, whilst the latter acted as a motor driving the former mechanically; the loss of power required to keep the whole combination in movement being determined by direct dynamometric measurement, and the power passing electrically from the one machine to the other being measured by ordinary electrical appliances.

The whole of the experiments were carried out at the works of Messrs. Mather and Platt, to whom we are indebted for the exceptional opportunities we have enjoyed of putting theoretical conclusions to the test of experiment on an engineering scale.

A CORRECTION.

By an oversight an article was inserted in our last issue under the heading of "New Voltmeter and Ammeter for Control in Working." The article inserted was merely an abstract, with translator's notes interpolated. The last paragraph, commencing "The lines of force" to the end have nothing to do with the abstract, and even if inserted the word "parallel" should in each case be read "perpendicular." In the last sentence the reference A and B refers to a figure similar to one in "Maxwell," Vol. 2, Fig. 18. If, however, the last paragraph be struck out, the remaining portion will refer to the instruments.—[ED. *E.*]

TELEPHONY IN AMERICA.

The following is an extract from the Bell Telephone Company's report for the year ended Dec. 31, 1885, read at Boston, at the annual meeting, on March 30, 1886 :—

The year ending Dec. 31, 1885, has not been marked by the increase of business of previous years; but although there has been a loss of subscribers in exchanges at certain points, on the whole the licensed companies have more than held their own, the total number of subscribers showing an increase of 2,969, and of telephones in use of 4,466 during the year. The comparative statistics which follow are substantially accurate; but, as usual, we are prevented from giving figures with the precision which would be possible if the entire telephone system were managed by us directly :—

Exchange Connections.

The estimated number of exchange connections daily in the United States is 746,517, or a total per year of 272,478,705. The number of calls per subscriber varies in different exchanges from 2 to 10 daily, the average throughout the United States being $5\frac{43}{100}$, as compared with $5\frac{18}{100}$, the number reported last year, an increase of about 5 per cent. The average cost to the subscriber varies—according to the size of the exchange and the character of the service—from 2 to 7 cents per connection.

Extra-Territorial Business.

The average daily number of extra-territorial connections is 6,663, or total number per year of 2,431,995. The extra-territorial earnings, as reported, amounted to \$538,740.43, of which this company's share is \$72,677.28 cents, an increase over 1884 of \$5,411.63 cents.

Last year's statement included the connections between exchanges of the New York and New Jersey, and the Pacific Bell and Sunset Companies, on the receipts from which we receive no percentage. These do not appear this year, which will account for the apparent decrease in the number of connections.

The removal of open wires from house-tops to overhead cables and to underground conduits has continued, the progress in the latter respect being especially encouraging. The system must always be a mixed one, as the final distribution of the wires to the customers, and the method of reaching places where underground work would be too costly, must still be overhead; but we think that within a few years in all large cities the open wires will be placed in cables above or under ground to such an extent, at least so far as telephone companies are concerned, that the overhead wire nuisance will no longer be serious. In New York an amendment to the law which ordered all wires in New York city and Brooklyn under ground before last November was adopted, establishing a commission for each of these cities with power to supervise the execution of the law, and to arrange for placing the wires underground to such an extent as might be found practicable. In Brooklyn the commission has permitted the wire companies to begin their work, and 134 miles of underground wire have been placed there by the Telephone Company. In New York the Metropolitan Company, in August, 1885, filed with the commission the necessary plans and statements for an underground system, and applied for permission to prosecute the work, but so far without success, and the work in that city is at present at a standstill.

THE ATLANTIC CABLE COMPANIES.

The few remarks which we appended to our last week's announcement that a war of cable rates was about to be commenced between the four "pool" companies and the refractory "COMMERCIAL" Company showed that our sympathies were entirely on the side of the former; and on a closer investigation of the circumstances we have discovered no grounds for qualifying our verdict, but rather have been confirmed in the opinion that sooner or later some extreme measure of the kind proposed is inevitable, and that if no compromise is arrived at between now and the 5th of May the present is a very favourable time for beginning hostilities. Deplorable as are usually the consequences of a war of rates, there are some contingencies even more deplorable—the ruin of all the parties concerned. In self defence, and as a last resort, the stronger of two combatants may quite justifiably put forth his whole force to crush his opponent rather than tamely submit to being starved into a condition of feebleness from which there would be no recovery except on terms dictated by the weaker foe. But having declared war, it should be as cruel, as decisive, and as sharp as the assailants can make it; and we are glad to see that this is the course decided upon. A reduction from one shilling and eightpence a word to sixpence a word would in ordinary circumstances be suicidal, and under no conditions can it be beneficial; but as a precautionary or retaliatory measure the more drastic it is the more certain is it to be quickly over and done with.

To be effectual it need not be ruinous to the people against whom the reduction is aimed. They have only to do what their predecessors have done, and what in the nature of things competitive cable companies must always do to save themselves from extinction, namely to abandon competition and give their minds to legitimate business. The Bennett-Mackay —or more correctly, since Mr. BENNETT took a back seat, the Mackay-Bennett—Cables were laid with the ostensible object of reducing the rates of the existing cable lines. There were more than enough of them to deal with the actual or prospective traffic; and the rate of two shillings a word was not returning a very luxurious dividend to the original cable company, or to any of its imitators, whom stress of competition had compelled it to buy up, or to share with them a common purse. The rival cable did succeed in reducing the rate by fourpence a word, with the result that the aggregate traffic, divided among five companies instead of four, and at rates reduced so as to tell seriously upon receipts, but not to materially stimulate business, has inflicted a heavy pecuniary loss upon four of the competitors, and probably also upon the fifth. We may suspect that the ostensible object of the Mackay-Bennett's "Commercial" venture was not its real object. But be that as it may, those two astute speculators may be credited with having counted among their risks that of a combination hostile to their existence as independent rivals. They cannot complain of harsh or unfair treatment, even if the very worst befall them; they set the example of applying purely business considerations to their own speculation, and they must not expect to obtain exemption for themselves on mere sentimental grounds. The COMMERCIAL Company was a reckless and superfluous competitor in the field of Atlantic telegraphy; and the fact that it was not the first offender only makes its intrusion the more inexcusable and intolerable.

We are not precisely informed as to the terms on which the ANGLO-AMERICAN, the DIRECT UNITED STATES, the WESTERN UNION, and the FRENCH ATLANTIC Companies have invited the COMMERCIAL to join their friendly arrangement; but we may take it that it is on a joint purse basis common to all the rest. Down to the moment of writing this the COMMERCIAL Company rejects these overtures, counting, perhaps, on some special advantages which it claims to enjoy in possessing a direct sea route. Possibly, also, its concession from the French Government, conditional, we believe, upon the rates being not higher than two francs a word, may have some weight, though, as their main cables are forked on British soil, the French agreement need prove no insurmountable obstacle to an understanding with the English Companies. But whatever the immediate cause of hesitation, we have little doubt that the pinch of necessity will soon disclose a way to get out of the difficulty. And we make no scruple in repeating that the pinch should be as painful as the attacking forces can anyhow afford to inflict. The sixpenny rate is to extend not merely to the cable lines but to all the area over which the COMMERCIAL have influence on land, and to every place to which it can possibly extend. The "BALTIMORE and OHIO RAILWAY" district, the "POSTAL TELEGRAPH," and the "BANKERS' and MERCHANTS'" lines, all of which are feeders of the COMMERCIAL Cable on the side of the United States, are to be embraced by the war tariffs; and, in short, the COMMERCIAL Company are to be compelled to accept their own particular

Digitized by Google

traffic at a loss, or to see it slip out of their hands altogether, whilst the other Companies will at least reap the advantage of higher land rates to the larger area over which their influence prevails.

Such is the view we naturally take of the situation on this side the water. In New York it seems they take quite another. The representatives of the COMMERCIAL Cable, it is reported, have hit upon the novel idea of appealing to the public to help them in the coming struggle. We call it novel, because although such appeals are not wholly unknown, they have never in our recollection been made by the very party which has the least claim to be listened to. Despite the obvious inconsistency of the thing, American business men are being invited on large placards to "rally round" the COMMERCIAL Company, to resist monopoly, and sustain cheap rates. We are quite sure of their disposition to support cheap rates, and for that very reason they will patronise the sixpenny cables so long as their custom is accepted at the price. As to monopoly, the public trouble themselves extremely little with abstract principles; and when it comes to a question of "rallying round," that cry is just as good and just as futile for an old company as for the new. Nobody rallied round the ANGLO, or the DIRECT, or the WESTERN UNION when the COMMERCIAL started to cut down their rates; and either the Mackay-Bennett people must be more simple, or the American people more self-denying than we take them to be, if an appeal for help at high prices is more effectual from one cable than when it came from three or four. The proprietors of the COMMERCIAL Cable, we fancy, have yet to learn the lesson which they have made it their particular boast to teach, namely, that customers will buy at the cheapest store, no matter what becomes of the opposition storekeeper. Yesterday the Company issued a circular, which we print elsewhere, reducing their rate to 1s., and asking their patrons to make a temporary sacrifice, "on the assurance that if we are vigorously backed up now the tariff shall return to the original figure—viz., 1s. 8d." The wording of this document is sufficiently singular; but the meaning of it is simply absurd.

CORRESPONDENCE.

PROFESSOR HUGHES ON HIS CRITICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed several criticisms in your valuable journal upon my paper on "self-induction," which I believe require a few remarks in reply.

The criticisms may be divided into three classes.

First—Prof. H. F. Weber shows that the method which I employed admits of numerous errors, and consequently infers that the results which I have announced are due to an "incorrect interpretation."

Second—Mr. Oliver Heaviside points out that upon a close examination it will be found that all the effects which I have described are well known to mathematicians, and consequently old.

Third—Mr. Willoughby Smith points out that the results which I have announced are contrary to theory and practice, and demonstrates that he is unable to obtain any difference even between iron and copper.

I must say that I am unable to agree with these opposing views, for if we assume with Mr. Heaviside that all my results are contained in some mathematical formula of which I am unaware, then the mathematicians ought to feel extremely grateful for the experimental proof which I have furnished them; if, on the other hand, we agree with Mr. Willoughby Smith, then the formula and my results should at once be abandoned as experimentally untrue.

Prof. Weber's objection is more serious, and I fully admit that it is possible to make very serious errors if the sonometer is not calibrated, or if we do not appreciate the errors that can be easily introduced. I feel sure that Prof. Weber could have seen how such errors could have been avoided, and this even by several means that I have indicated, such as making comparative tests between wires of the same length and resistance, so that no change took place in the bridge adjustment except that due to the differential results.

The only question which I consider important is, Are the effects which I announced true physical effects due to nature or form of the conductor, or are they simply due to some peculiarity of the method which I employed? To answer this I have constructed an instrument based upon an entirely different method, one of extreme simplicity, and one which does not allow of any possible error.

I propose to publish a description of this instrument (together with the results obtained) during the coming month, when I hope that its demonstrations will prove clearly all that I have said as to the influence of the form as well as the nature of the conductor upon its self-induction.—Yours, &c.,

D. E. HUGHES.

(Translation.)

HYPNOTIC EFFECT OF THE ELECTRICAL CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have the honour to address you a brief reply to the question propounded by one of your correspondents.

The efficacy of the treatment of insomnia by electricity is one of the best-established facts of electro-therapeutics. The voltaic current, the faradaic current, or even static electricity may be employed. I will confine myself to describing in detail the voltaic process, which is the readiest and the most certain. I will assume we have the ordinary medical battery, *i.e.*, one composed of Daniell or Leclanché elements, provided, amongst other accessories, with a collecting-switch, allowing of the gradual introduction into the circuit of the requisite number of elements without interrupting the current, and with a galvanometer graduated in fractions of an ampere. The electrodes are of the ordinary pad form, carbon or metal covered with cloth or with chamois leather. The negative electrode should be about 7 centimetres, and the positive 5 centimetres in diameter. After having soaked them in ordinary water, they are applied to the two temples, behind and above the eyebrow, with a moderate pressure. The negative pad may be entrusted to an assistant or to the patient himself; the positive is held by the operator. After waiting for a minute to allow the epidermis to become moistened the switch is moved so as to gradually insert the elements into the circuit. At the same time the galvanometer is watched, and as soon as it indicates 15 ten-thousandths of an ampere the movement of the switch is discontinued and the current is allowed to act. Ordinarily, the deflection of the needle slowly increases; and if the rate of increase be too rapid, or, in any case, as soon as it approaches 30 ten-thousandths, the number of elements must be diminished. After the current, maintained within these limits, has passed for two minutes, it must be interrupted. This is the delicate portion of the operation; the interruption must be gradual, and the positive electrode must be removed before the other. The best means formerly, unless I am mistaken, indicated by (?) Ziemssen is to slide the positive pad, whilst maintaining the pressure, up to the roots of the hair, and finally to pass it on to the hair. During this manipulation the needle returns towards zero; and, at the end of it, the current has been interrupted without the production of any shock. In spite of these precautions it is difficult, in the case of certain patients, to avoid certain luminous sensations (phosphines electriques), and a certain amount of giddiness. These phenomena are absolutely without danger in the case of the current here employed. It often happens that I purposely produce them; since I have observed that when they are produced success is more certain. The only reason for avoiding them is that with very excitable or timid patients the resulting emotions may

Digitized by Google

augment their nervousness and cause them to be afraid of the treatment.

I have not mentioned the number of elements to be used, since this depends upon the (very variable) electrical resistance of the patients. The galvanometric indication is alone of importance, and is sufficient for the purpose in view.

By means of this very simple treatment, which I have employed hundreds of times, the most stubborn cases of insomnia have, almost without exception, been overcome. Ordinarily, this is what occurs. If the galvanisation has taken place in the morning the patient experiences no particular sensation for the remainder of the day, only in some cases a little sleepiness, which increases towards night; but next day he is surprised to find that he has slept for eight or nine hours without interruption. The effect of a single sitting continues, in diminishing degree, during two or three days, after which the application must be repeated.

For the most part, a few sittings are sufficient to effect a cure. Should the first application not have a very marked effect, the process must be modified. Thus, the positive electrode may be applied to the forehead and the other to the back of the neck; or the very efficacious method of applying the positive electrode successively to the eyes may be adopted. In the last case the current must be weaker than usual (from 8 to 15 ten-thousandths), and the application shorter (one minute for each eye).

Another simple and harmless method consists in applying to and retaining upon the temples plates of tin covered with chamois leather, serving as electrodes to one or two fluid elements of Trouvé. The application should last for two hours or even much longer. The battery is placed in the patient's pocket, or, should he be in bed, beneath his pillow.

If, in an exceptional case, none of these methods succeeds, electricity need not on that account be given up. Some of the numerous processes of faradisation, or of applying statical electricity may be, and, in fact, sometimes are, more efficacious.

It must be understood that what is here referred to is insomnia properly so called, and not the sleeplessness occasioned by pain in any portion of the body. I repeat that, by means of the processes which I have just described, I have restored sleep to patients who declared that they had not slept for months or years, and who took, without effect, enormous doses of morphia or chloral.

I called the attention of medical men to these facts in a note published ten years ago in the *Journal des Connaissances Médicales*. But I am far from wishing that I should be thought the inventor of the process. It was, and it still is, more or less indicated in works on electro-therapeutics. Nevertheless it seems to me that it is not at the present time sufficiently known and practised.—Receive, &c.

(Signed) DR. R. VIGOUREUX,
Chief of the Electro-Therapeutic Service
Paris, 24th April, 1886. at the Salpêtrière.

LECTURE APPARATUS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me through the medium of your columns to call the attention of instrument makers to a much required improvement in a simple lecture apparatus?

The distribution of electricity, when in equilibrium, upon the surface of conductors is usually experimentally shown by means of a metal sphere mounted upon an insulating stand, and which can be enclosed within a hollow sphere formed of two metal hemispheres to which insulating handles are attached. The internal sphere appears to be invariably made of such a size that the two hemispheres only just contain it, and the ordinary text books all figure the apparatus in this way. The result is that it is almost impossible to withdraw the hemispheres without allowing them to touch the inner sphere after separation, which makes it most unsatisfactory for a lecture experiment. The difficulty is easily obviated by making the diameter of the internal sphere considerably smaller than that of the hemispheres, which makes the experiment perfectly easy and certain, and, of course, it does not affect its principle in any way, for it is clearly unnecessary to have many points of contact between the two conducting spheres.

It is an improvement in the neatness of the experiment to have semi-circular portions of metal filed away from the hemispheres so that the internal sphere can be completely enclosed by them, with the exception of the circular opening so formed in the external sphere, and which is required in order to allow the insulating stem of the inner sphere to pass through the outer one.—Yours, &c. G. W. VON TUNZELMANN.

THE TELEPHONE.—A CHEEKY QUESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: After reading several telephone cases, and seeing the wonderful area covered by certain patents, I am getting seriously uneasy in my mind whether I am not myself an infringement.

The other day, when inspecting the leads of an alternating circuit, I touched a badly insulated joint, and made a remark suitable to the occasion. What that remark was is of no consequence, but three friends heard it—at a distance. They assure me that the articulation was most distinct and very loud, and are unanimous in the opinion that it was due solely to the passage of an undulatory current through my body, as they are certain that I should never—no, never!—have made that remark of my own volition.

Further, I have taken the opinion of experts, and they all agree that the cheek is a diaphragm necessary to perfect articulation. That this is so is evident from the fact that if the cheek could be taken out of a telephone company there would be silence, or at most a confused grumbling sound, instead of loud articulation about patent rights. The experiment is a difficult one, and has never yet been properly carried out.

Now, what I want to know is this:—Can I be legally described as "an apparatus with a diaphragm or diaphragms which, when actuated by the passage of an undulatory current of electricity, produces and transmits to a distance articulate speech?" Because, if so, considering that I was manufactured without the license and consent of any telephone company, I think it would be advisable to "git" before an injunction is obtained against me and an order of the Court for my destruction.—Yours, &c., D.

Feast of St. Lubbock, 1886.

RESISTANCE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method of altering the bridge to make a B.A.U. box measure illegal ohms was mentioned in a letter to you of March 7th, 1885. It was also suggested that the Congress might go below, but alas! they are not gone.—Yours, &c.,

Chelmsford. JAS. SWINBURNE.

NEW EXPERIMENTS ON ELECTRICITY, HEAT, AND LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my letter to you of the 1st curt., I produced experimental proof that electricity is a component part of the substance which we call ozone, and I broached the opinion that the flash of light seen by MM. Hautefeuille and Chappuis in the glass tube must have been the result of the union of a portion of the extra heat with the electricity which had formed a component part of the ozone prior to the ozone's decomposition, which caused the explosion. To determine the connection between, or rather the relative positions of, electricity and heat, I made the following experiments:—

I have a Geissler vacuum tube of the shape of the letter V, each leg of which measures 7½in. in length, and the outside diameter of it is ¾in. The platinum terminals being at the upper ends of the letter V, I adjusted this tube so that a powerful current of electricity passed through it from a

Ruhmkorff coil. I noted the amount of light produced within the tube while it was thus in the atmosphere of the room, at a temperature of + 67° F. I then had it placed in a freezing mixture of ice and salt, at a temperature of + 5° F. In this position the light within the tube was greatly diminished. I then had the same tube, with the same arrangement of coil, immersed in boiling water. Immediately a wonderful effect was produced. There was a greatly increased amount of light within the tube; a brilliant blueish flame filled both legs of the tube, and also striæ appeared of a very marked kind. As the latter never appeared in the tube when it was not in the boiling water, this leads to the conclusion that the striæ are produced by the increments of heat passing through the glass into the interior of the tube.

These experiments establish that the light produced in the tube which MM. Hautefeuille and Chappuis saw must have been the result of the union of the heat and electricity within the tube; and, further, these experiments lead to the conclusion that if we could place the V Geissler tube or an incandescent electric lamp in an atmosphere void of heat, no light would be seen in them, although a powerful current of electricity were passed through them.—Yours, &c.,

8, Merchiston-park, JAMES JOHNSTONE.
Edinburgh, 27th April, 1886.

DOUBLE CUT-OUTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of the 16th we notice an illustration of a cut-out which is said to have been designed by Messrs.

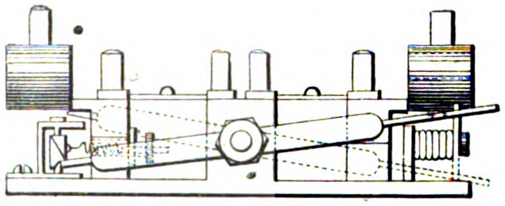

FIG. 1.

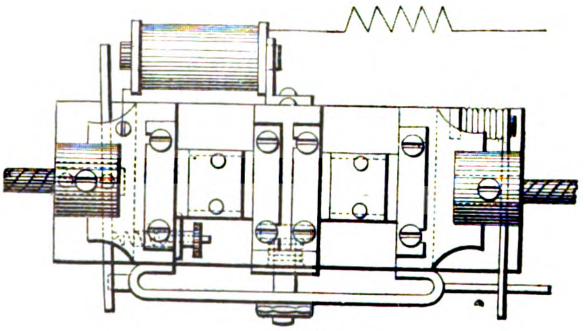

FIG. 2.

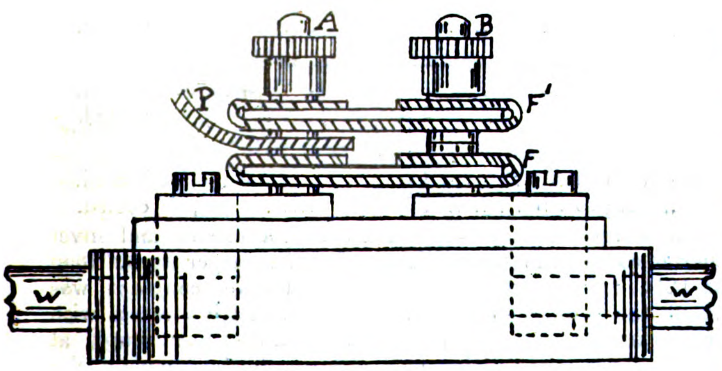

FIG. 3.

Baily and Grundy, "to remedy a defect in the older forms." We are sure these gentlemen are not acquainted with the early forms of the Hedges duplex cut-out, such as were shown at the Crystal Palace Exhibition, or they would not have claimed Mr. Hedges' original pattern, which has been superseded by the improved duplex form we now make, and which is more compact. We have supplied hundreds of these, and have lately designed a self-acting arrangement, so that the spare foil is automatically substituted for the one melted. The accompanying illustrations (Figs. 1 and 2) will render this easily understood; the switching lever is tripped by the action of a small electro-magnet, wound with fine wire, which is placed as a shunt with the line. Another arrangement, where eyelet foils are used, is shown by Fig. 3; the spare foil marked F_1 is placed on the top of the working one F, and is brought into action by withdrawing the paper insulating washer B, which then allows the current to pass through F_1.—Yours, &c.,

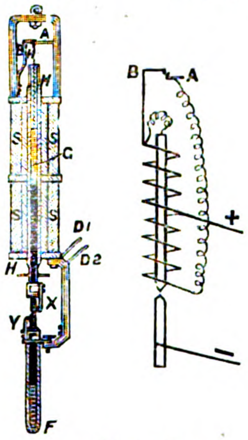
WILLIAM GRANGER, Manager of the Globe Electrical and Engineering Company.

20, Dartmouth-street, Westminster, S.W.,
April 21, 1886.

AN ARC LAMP FOR SMALL CURRENTS.

The Scharn-Weber lamp, a longitudinal section of which is shown in Fig 1, according to the *Centralblatt für Electrotechnik*, acts very well. For the regulation of the distance between the carbons three agents are employed—elasticity, gravity, and electro-magnetic attraction. The first is used only with the lower carbon, which a spiral spring gradually allows to rise as its weight decreases. The upper carbon is inserted in an iron tube, H, and is pressed down by a weight, G. This tube acts as the core of a solenoid, S. When the circuit is open the upper carbon rests on the under one. When the circuit is closed the tube, and with it the carbon, is so far drawn into the solenoid as its own weight and the above-mentioned weight (which rests on it) allow. Thus the arc is formed. As the carbon burns away the resistance becomes greater, and the current in the solenoid falls off, since it is in the same circuit, the attraction decreases and gravity acts and lowers the carbon till equilibrium is again restored. The course of the current can be seen from Fig. 2.

FIG. 1. FIG. 2.



Scharn-Weber Lamp.

If one lamp alone is in circuit its solenoid is simple; but if several lamps are in the same circuit each has a different coil. The throwing of the lamp out of circuit when the carbon is burnt down to a certain point is effected by a contrivance situated in its upper part. The weight G hangs by a chain to the spring A, which is opposite to another spring, B. The two springs press their points against each other. If the carbon is so far burnt away that the chain is stretched, the spring A is drawn down, and its point passes under that of the spring B, and the latter, released from the pressure of A, springs forward. The under part of B is covered with ebonite, so that the circuit through A and B is broken by this action. A novelty in these lamps is the incombustible holders of the carbons, which are pieces of osmium embedded in platiniridium.

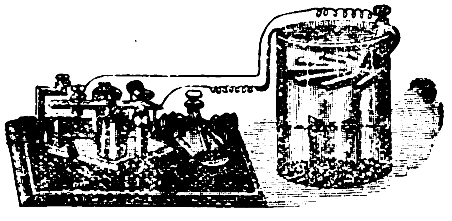
THE DIAMOND LEARNER'S TELEGRAPH INSTRUMENT.

The leading feature of the instrument here shown consists in so forming the sounder, anvil, and key that they have a diamond-shaped cross-section, and in so making the base of the sounder and of the anvil that when set up the two form a diamond outline. The magnets of the sounder are enclosed in metallic cases, and the various metallic portions of the instrument can be made to present the appearance of either gold, bronze, or brass. The black baseboard is of wood.



The Diamond Learner's Telegraph Instrument.

This instrument—designed by the Novelty Electric Company, of 5th and Locusts-streets, Philadelphia, Pa.— presents a unique and attractive appearance.—*Electrical World.*

ON THE PELTIER EFFECT AT DIFFERENT TEMPERATURES.*

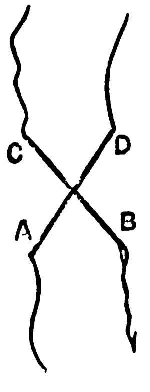
BY G. GORE, LL.D., F.R.S.

In order to examine this question I made the following experiments :—

A current of ·10 ampere was passed, during five minutes, through a thermo-electric pile, composed of thirty-six pairs of bismuth and antimony, at a uniform temperature of 8° C. The current was then stopped, and the terminals of the pile at once connected with an astatic galvanometer of 100 ohms resistance—the needles gave a swing of 8 degrees. The pile was then heated in a hot-water jacketed chamber to a uniform temperature of 65° C., and the experiment exactly repeated with the current of its original strength ; the needles now gave a swing of 17 degrees. These experiments were again exactly repeated, but with the pile at 9° C. and 85° C. ; the deflections were 8 degrees at 9° C. and 20 at 85° C.

These results indicate that the difference of temperature produced at and near the two junctions of a bismuth and antimony thermo-couple, by the passage of an electric current through them, is more than twice as great at 85° C. as at 8° C. As the amount of resistance of the galvanometer was large in comparison with that of the pile, the increased strength of current was due to increase of electromotive force.

In order to examine the amount of Peltier effect produced



at the two junctions of the pile separately, a current of ·2 ampere was passed, during about twenty seconds, from A to B, through a cross composed of two wires ; A D being of iron, ·5 millim. diameter, and B C of German silver, ·4 millim. diameter, whilst their opposite ends, C, D, were attached to a galvanometer, of about 2·0 ohms' resistance, by means of slender wires of copper.

With the entire cross and the adjoining portions of its conducting wires at 10° C., on passing the current from iron through the junction to German silver, a deflection of 3 degrees was produced, showing that the junction was heated ; and on passing it from German silver to iron, the deflection was 2 degrees in the same direction, showing that the junction was again heated, but in a less degree. These results were obtained several times. On repeating these experiments carefully in a similar manner, but with the cross and its attachments at 90° C., the current from iron through the junction to German silver produced a deflection of 4 degrees, indicating heat at the junction ; and on passing it from German silver to iron, the deflection was 2 degrees in the same direction, the junction being again heated.

These results show—1st, that with a thermo-couple composed of iron and German silver a current of uniform strength, passed from iron to German silver, evolved more heat than when passed in the opposite direction, whether the pile was at 10° C., or 90° C. 2nd, that when the current was passed from iron to German silver, it evolved more heat at and near the junction when the couple was at 90° C. than when it was at 10° C. And 3rd, that when it was passed from German silver to iron the amounts of heat evolved were about the same when the couple was at 90° as when it was at 10° C.

With the same strength of current, and a cross formed of bismuth and antimony, with the cross and its connections at 12° C., on passing the current from the bismuth through the junction to the antimony, a deflection of 8 degrees was produced, showing that the junction was cooled ; and on passing it in the opposite direction, the deflection was 8 degrees in the opposite direction, showing a heating effect. With the cross, &c., at 93° C., passing the current from the bismuth through the junction to the antimony produced a deflection of 10 degrees and a cooling effect ; and passing it in an opposite direction produced a deflection of 10 degrees and a heating effect.

From these results it appears that the Peltier effect, both of heating and cooling, with a thermo couple of bismuth and antimony, was considerably larger at 93° than at 12° C. Also that the amounts of heating and cooling effect were about equal, whether the couple was at 12° or 93°C.

Similar experiments were made with a cross formed of bismuth and silver, and with one composed of antimony and silver, the silver wire being ·5 millim. diameter, with the same strength of current as before. The results were as follows (the direction of current given in each case is that through the junction) :—

Direction of Current.	Deflection.	Thermal Effect.
Bismuth and Silver at 12°C.		
From Bi to Ag	2·0	...... Junction cooled.
„ Ag to Bi	2·0 to 2·5	„ heated.
Bismuth and Silver at 92° C.		
From Bi to Ag	3·0	...... Junction cooled.
„ Ag to Bi	3·0	...... „ heated.
Antimony and Silver at 12° C.		
From Sb to Ag	1·5	...... Junction heated.
„ Ag to Sb	1·5	...... „ cooled.
Antimony and Silver at 95° C.		
From Sb to Ag	1·5	...... Junction heated.
„ Ag to Sb	1·5	...... „ cooled.

These results show—1st. That with a bismuth and silver thermo-couple, the total Peltier effect was larger at 92° than at 12° C. ; 2nd, with an antimony and silver couple it was about the same at 95° as at 12° C. ; 3rd, that it was less with an antimony-silver than with a bismuth-silver couple at each temperature ; 4th, with a bismuth-silver couple the heating effect at 12° C. was somewhat greater than the cooling one, and at 92° C. the heating and cooling effects were about equal ; and 5th, that with an antimony-silver pair the heating and cooling effects both at 12° and 95° C. were all about alike.

* Read before the Birmingham Philosophical Society, February 11, 1886. From the *Phil. Mag.* for April.

Digitized by Google

With the couples formed of bismuth antimony, iron-German-silver, and bismuth-silver, the total Peltier effect was greater in each case at the higher temperature than at the lower one, but with the antimony-silver one, the effects at the two temperatures were about equal.

All the results were probably affected to some extent by the influence of "electric convection of heat."

The whole of the results obtained (after making due allowance for differences in the specimens of medals employed by different experimentalists) agree with the thermo-electric diagram given in the manual on "Heat," by P. G. Tait.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 478.)

Theories which are founded on dynamical considerations and which take into account the action of the dielectric.

In the theories we have hitherto considered, the influence of the medium which exists between the currents has been left altogether out of account. In the theories which we shall now proceed to discuss the influence of this medium is taken into consideration. This is, perhaps, the most important step that has ever been made in the theory of electricity, though from a practical point of view it is comparatively of little importance; in fact, for practical purposes almost any one of the preceding theories will satisfy every requirement.

Faraday was the first to look upon the dielectric as an important agent in electrical phenomena; he was led to this by his desire to get rid, as far as possible, of the idea of action at a distance, which was so prevalent in his time, but to which his researches have given the death-blow. In his "Experimental Researches," § 1164, speaking of electrostatic induction, he says, "I was led to suspect that common induction itself was in all cases an action of contiguous particles, and that electrical action at a distance (*i.e.*, ordinary inductive action) never occurred except through the influence of surrounding matter." And later on he gives his views as to the nature of the effect in the medium; in § 1298 of the "Researches" he says, "Induction appears to consist in a certain polarised state of the particles into which they are thrown by the electrified body sustaining the action, the particles assuming positive and negative points or parts, which are symmetrically arranged with respect to each other and the inducting surfaces or particles. The state must be a forced one, for it is originated and sustained only by force, and sinks to the normal or quiescent state when that force is removed. It can be continued only in insulators by the same portion of electricity, because they only can retain this state of the particles." He gives an experimental illustration of his view in § 1350. He says, "As an illustration of the condition of the polarised particles in a dielectric under induction I may describe an experiment. Put in a glass vessel some clear rectified oil of turpentine, and introduce two wires passing through glass tubes, when they coincide with the surface of the fluid and terminating in balls or points. Cut some very clean dry white silk into small particles, and put these also into the liquid; then electrify one of the wires by an ordinary machine and discharge by the other. The silk will immediately gather from all parts of the liquid and form a band of particles reaching from wire to wire, and if touched by a glass rod will show considerable tenacity; yet the moment the supply of electricity ceases the band will fall away and disappear by the dispersion of its parts. The conduction by the silk is in this case very small, and after the best examination I could give to the effects, the impression on my mind is that the adhesion of the whole is due to the polarity which each filament acquires, exactly as the particles of iron between the poles of a horseshoe magnet are held together in one mass by a similar disposition of forces. The particles of silk therefore represent to me the condition of the molecules of the dielectric itself, which I assume to be polar, just as that of the silk is. In all cases of conductive discharge the contiguous polarised particles of the body are able to effect a neutralisation of their forces with greater or less facility, as the silk does also in a very slight degree. Further we are not able to carry the parallel, except in imagination; but if we could divide each particle of silk into two halves, and let each half travel until it met and united with the next half in an opposite state, it would then exert its carrying power (1307), and so far represent electrolytic discharge."

And it is not only in statical electricity that Faraday recognised the importance of the dielectric. When he is discussing his discovery of the induction of currents, which he ascribes to the assumption of what he called the electrotonic state by the body in which induced currents are developed, he says, § 73, "It may even exist in non-conductors," that is, that there is an electromotive force acting on the surrounding dielectric due to the variation in the primary current. Again, in § 1661, he says, "Now though we perceive the effects only in that portion of matter which, being in the neighbourhood, has conducting properties, yet hypothetically it is probable that the non-conducting matter has also its relations to, and is affected by, the disturbing causes, though we have not yet discovered them. Again and again the relation of conductors and non-conductors has been shown to be one, not of opposition in kind, but only in degree (1334, 1603); and therefore for this, as well as for other reasons, it is probable that what will affect a conductor will affect an insulator also, producing, perhaps, what may deserve the term of the electrotonic state (60, 242, 1114)." And though he was unable to detect these effects experimentally, the following paragraph (1728) shows that his belief in their existence was not shaken: "But then it may be asked, What is the relation of the properties of insulating bodies, such as air, sulphur, or lac, when they intervene in the line of magnetic action? The answer to this is at present merely conjectural. I have long thought there must be a particular condition of such bodies, corresponding to the state which causes currents in metals and other conductors (26, 53, 191, 201, 213); and considering that the bodies are insulators, one could expect that state to be one of tension. I have, by rotating non-conducting bodies near magnetic poles, and poles near them, and also by causing powerful electric currents to be suddenly formed and to cease around and about insulators in various directions, endeavoured to make some such state sensible, but have not succeeded. Nevertheless as any such state must be of exceedingly low intensity, because of the feeble intensity of the currents which are used to induce it, it may well be that the state may exist, and may be discoverable by some more expert experimentalist, though I have not been able to make it sensible."

Maxwell was the first to express Faraday's ideas in mathematical language. In his papers on "Physical Line of Force" in the *Philosophical Magazine* for March, April, May, 1861, and January, February, 1862, he develops a theory of electricity according to which the energy of the electro-magnetic field resides in the dielectric as well as in the conductors; later, in the *Philosophical Transactions* for 1865, he greatly extended Faraday's ideas as well as put them into definite mathematical language, and this without reference to any special theory of the mechanism which produces electrical phenomena. We shall devote some time to discussing Maxwell's theory, as it is freer from serious objections than any other, while at the same time it covers a much wider ground.

We shall begin by referring to Maxwell's view of the state of the dielectric in the electric field. Maxwell supposes that the dielectric is changed, and perhaps the clearest way of describing this change is that of Faraday in the extract already quoted. Maxwell's nomenclature as to this change is a little unfortunate; instead of speaking, like Faraday, of the polarisation of the dielectric, he speaks of the change as consisting of an electric displacement, which in isotropic media is in the direction of the electromotive force. Mathematically the two things are identical; we may either say of a wire that it is negatively electrified at one end A, and positively at the other end B, or else that there is a displacement of positive electricity from A to B, so that there is an excess of positive electricity at B and a deficiency at A. But though the words in a mathematical sense are identical, still the word displacement seems to connote special qualities which limit the generality of the concep-

Digitized by Google

tion in an undesirable way; the word displacement seems to imply motion in the direction of displacement, while polarisation only implies that there is a vector change of some kind in the dielectric. The condition of the dielectric is quite analogous to the state of a piece of soft iron placed in a magnetic field. The polarisation or displacement is in isotropic media in the direction of the electromotive force and proportional to it, just as the magnetic induction in isotropic media is in the direction of the magnetic force and proportional to it. It was this proportionality, combined with the fact that as soon as the electromotive force is removed the dielectric springs back, as it were, to its original state, that led Maxwell to use the word displacement. He looked on the case as analogous to that of an elastic solid, which springs back to its original position when the external force is removed, and in which the displacement is proportional to the impressed force. To avoid any unnecessary definiteness we shall use the term dielectric polarisation instead of electric displacement. Thus, according to this view, the dielectric in the electric field is polarised. This polarisation means change of structure of some kind, and to produce this change of structure work is required. The energy in the polarised dielectric will be greater than the energy when it was unpolarised, for if the energy were less the dielectric would go into the polarised condition of itself, without the application of any external forces.

It is rather difficult to see what is meant in Maxwell's theory by the phrase "quantity of electricity." According to the old two-fluid theory an electrified body was supposed to contain a certain quantity of something called electricity, rules were given for measuring this quantity, and the phrase "quantity of electricity" meant something quite definite. In Maxwell's theory, where everything is referred to the dielectric, the meaning of the phrase is not so obvious. We can, however, arrive at some idea of what is meant by the consideration of what are called "tubes of force." Let us suppose at first that the dielectric is air. A line of force is a line whose direction at any point coincides with the direction of the electromotive force at that point, so that we may conceive the electric field to be filled with lines of force. If we consider the lines of force passing through some small closed curve, they will form a tube, and such a tube is called a tube of force; and if the dimensions of the tube are such that the product of the cross section at any point and the electromotive force at that point is constant and equal to 4π, the tube is called a unit tube. We may thus conceive space to be filled with unit tubes of forces. Since the electromotive force inside a conductor vanishes these tubes will end at the surface of a conductor, and the quantity of electricity on the conductor will be equal to the excess of the number of lines of force which leave the conductor over those which enter it. A tube is said to leave the conductor when the direction of the electromotive force is along the normal drawn outwards, and to enter it when the direction of the electromotive force is along the normal drawn inwards. As the conductor moves about it may be supposed to carry the tubes of force along with it, so that the number of tubes which end on the conductor remains constant. This way of looking at electrification is quite satisfactory as long as we keep to one dielectric air; when we have to consider different dielectrics it requires modification, because the electromotive force changes abruptly as we pass from one dielectric into another, so that a tube which was a unit tube in one dielectric is not so in another. It is easy, however, to extend the definition of unit tubes so as to meet this difficulty; for if the tubes pass from one dielectric, A, into another, B, the ratio of the product of the cross section and electromotive force is constant for all the tubes, and depends only on the nature of the dielectrics; this ratio is the ratio of the specific inductive capacities in B and A. Air is taken as the standard dielectric, and the specific inductive capacity of another dielectric, A, is the ratio of the product of the electromotive force and cross section of a tube in air to the product of the same quantities for the same tube in the dielectric A. Thus, if we amend our definition and say that a circuit tube is one such that the product of the cross section, the electromotive force, and the specific inductive capacity of the medium in which the cross section is situated is equal to 4π, then the quantity of electricity on a conductor is equal to the excess of the number of unit tubes which leave the conductor over the number of those which enter it. In this way we get an idea of what is meant by "quantity of electricity" in Maxwell's theory. Maxwell accounts for the forces observed between electrified bodies by a system of stresses in the dielectric separating them; as, however, at present we wish to compare Maxwell's theory with other theories which do not touch upon this point, we shall discuss this part of the theory separately later on and go on to discuss those points which are involved in all the theories.

The next great point in Maxwell's theory is the development of Faraday's remark that the electrotonic state may exist even in non-conductors, *i.e.*, that the dielectric surrounding a changing current is acted on by electromotive forces which polarise it. This statement is one as to whose truth nobody seems to entertain any doubt, whilst the statement that changes in the dielectric polarisation produce effects analogous to those produced by ordinary conduction currents is by no means so universally received; and yet the one seems the necessary consequence of the other.

(To be continued.)

THE CHANGES PRODUCED BY MAGNETISATION IN THE LENGTH OF IRON WIRES UNDER TENSION.*

In a paper communicated to the Royal Society about a year ago, the author discussed the results of certain experiments made by Joule in relation to the effects of magnetism upon the dimensions of iron and steel bars.

It is well known that the length of an iron rod is in general slightly increased by magnetisation. Joule enunciated the law that the elongation is proportional in a given bar to the square of the magnetic intensity, and that it ceases to increase after the iron is fully saturated. The author's experiments, made with a greater range of magnetising forces and with thinner rods than those used by Joule, showed that if the magnetising current were gradually increased after the so-called saturation point of the iron had been reached, the elongation, instead of remaining at a maximum, was diminished, until, when the current had attained a certain strength, the original length of the rod was unaltered, and if this strength were exceeded, actual *retraction* was produced.

Joule also found that when the experiment was performed upon an iron wire stretched by a weight, the magnetic extension was in all cases diminished, and if the weight were considerable, magnetisation caused retraction instead of elongation. From these facts he appears to have formed the conclusion that, under a certain critical tension (differing for different specimens of iron, but independent of the magnetising force), magnetisation would produce no effect whatever upon the dimensions of the wire. In one of his experiments a certain iron wire loaded with a weight of 408lbs. was found to be slightly elongated when magnetised; the weight was then increased to 740lbs., with the result that magnetisation was accompanied by a slight retraction. In both cases the magnetising currents varied over a considerable range, and the smaller ones were without any visible effect. Commenting upon these results, Joule conjectured that "with a tension of about 600lbs (which number is roughly the mean of 408 and 740) the effect on the dimensions of the wire would cease altogether in the limits of the electric currents employed in the above experiments."

In reference to this surmise the author in his paper of last year expressed his belief that, if Joule had actually made the experiment, he would have found that the length of the wire was increased by a weak current, that a current of medium strength would have had no effect whatever, and that one of his stronger currents would have caused the wire to retract. He had, in fact, reason to believe that the effect of tension was to diminish the "critical magnetising force" (which produces maximum elongation), so that the retraction which is found to occur in all iron rods when a sufficient magnetising force is employed, is observed with smaller magnetising currents when the rod is stretched than when it is free, but want of suitable apparatus prevented him from submitting this idea to the test of direct experiment.

He has lately modified the instrument, which was described in his former paper, in such a manner that it can be used for observing the effects of magnetisation upon rods and wires under traction, and the results of a series of experiments made with it are presented in a synoptical form in the subjoined table. Four specimens

The magnetic field of the centre of the coil = current × 92. One scale division = one five millionth part of the length of the wire.

of iron were used. The first was a wire of commercial iron, 1·2 mm. in diameter, which had been softened by heating in a gas flame; the second was a strip of annealed charcoal iron, 5·5 mm. wide and 0·55 mm. thick, its sectional area being about 3 mm.; the third was a piece of hard unannealed wire, 2·6 mm. in diameter; and the last was a wire of very pure soft iron, 3·25 mm. in diameter, which had been carefully annealed. These were successively fixed in the apparatus, and loaded with weights varying from 3lb. to 14lb. While under the influence of each load four observations were made in the case of each wire:—(1) A determination was attempted of the smallest magnetising current which sensibly affected the length of the wire in the direction of elongation or retraction. (2) The current producing *maximum* elongation (if any) and the extent of such maximum elongation were found. (3) A determination was made of the critical current which was without effect upon the original length of the wire, *i.e.*, the current of such strength that a weaker one would cause elongation and a stronger one retraction. (4) The retraction produced by a fixed current of 1·6 ampere was measured.

The figures recorded in the table disclose the following facts:—

(1) The effects produced by magnetisation upon the length of an iron wire stretched by a weight are in general of the same character as those which have been shown in the former paper to occur in the case of a free iron rod. Under the influence of a gradually increasing magnetising force such a wire is at first elongated (unless the load be very great), then it returns to its original length, and finally it contracts.

(2) The maximum elongation diminishes as the load increases according to a law which seems to vary with different qualities of iron. If the ratio of the weight to the sectional area of the wire exceeds a certain limit, the maximum elongation (if any) is so small that the instrument fails to detect it.

(3) The retraction due to a given magnetising force is greater with heavy than with light loads.

(4) Both maximum elongation and neutrality (*i.e.* absence of both elongation and retraction) occur with smaller magnetising currents when the load is heavy than when it is light; retraction, therefore, begins at an earlier stage. Thus the anticipation expressed in the author's former paper is justified.

(5) The phenomena, both of elongation and of retraction, are, as might be expected, greater for thin than for thick wires, and for soft than for hard iron.

THE INDIAN TELEGRAPH DEPARTMENT.

The following letter appears in the *Homeward Mail*, over the signature of "600 Wallah":—

The staff sanctioned for the department in 1866 was 21; 1 director-general, Rs.2,500 to Rs.3,000; 1 deputy director-general, Rs.1,500 to Rs.1,800, by annual increment of Rs.50; 4 superintendents, 1st grade, Rs.1,050 to Rs.1,500, by annual increment of Rs.75; 8 superintendents, 2nd grade, Rs.800 to Rs.1,000, by annual increment of Rs.50; 7 superintendents, 3rd grade, Rs.600 to Rs.750, by annual increment of Rs.30; 88 assistant superintendents, Rs.200 to Rs.450, by annual increment of Rs.25. The changes made in and before 1880 were 44:—1 director-general, Rs.3,000; 1 deputy director-general, Rs.2,000; 2 directors, Rs.1,600 each; 4 superintendents, 1st grade, Rs.1,125 to Rs.1,500, by annual increment of Rs.75; 8 superintendents, 2nd grade, Rs.900 to Rs,1,050, by annual increment of Rs.30; 12 superintendents, 3rd grade, Rs.800; 16 superintendents, 4th grade, Rs.600; 50 assistant superintendents, Rs.250 to Rs.500, by annual increment of Rs.25. These changes may be summarised as follows:—Pay of the director-general increased by Rs.500; pay of the deputy director-general increased by Rs.500; two directors created on Rs,1,600 each. Pay of 1st grade superintendent raised by Rs.75; pay of 2nd grade superintendents raised by Rs.100; pay of 3rd grade superintendents, raised by Rs.200; 5 superintendents, 3rd grade, created on Rs.800; 16 superintendents, 4th grade, created on Rs.600. Pay of assistant superintendents raised by Rs.50. In other words, the direction and superintendence were increased by 23 officers, and the assistant superintendents reduced by 38 officers. The pay and service of the 21 senior officers on promotion are given below:—One 26 years, Rs.3,000; one 22 years, Rs.2,000; one 25 and one 22 years, Rs.1,600; direction, four. One 27, two 24, and one 21 years, Rs.1,125; superintendents, 1st grade, four. One 28, one 27, two 25, one 24, two 22, and two 19 years, Rs.900; superintendents, 2nd grade, nine. Two 22 years, Rs.800; superintendents, 3rd grade, two. One 25 and one 21 years, Rs.600; superintendents, 4th grade, two. The pay and service of the 23 remaining superintendents on promotion were:—One 18, one 17, two 15, four 14, and one 12 years, Rs.800; superintendents, 3rd grade, nine. One 18, one 16, four 15, three 13, three 12, and two 11 years, Rs.600; superintendents, 4th grade, fourteen. The distribution return of the department for 1885 gives the service of the 44 senior officers up to April 1, 1885, as follows:—

Service Years.	Direction.	Superintendents.				Total.	Grand Total.
		1st.	2nd.	3rd.	4th.		
30	—	—	—	—	1	1	1
29	—	—	1	—	—	1	2

Totals.....	4	4	8	12	16	44	

* Appointed since 1868.

There were besides 65 assistant superintendents, 15 in excess of the sanctioned number. Of the officers appointed since 1868 only 14 were in the grades of superintendents, and this has been accomplished by the supersession of senior officers. Since January 1, 1868, the pay of the 8 senior assistant superintendents in the fourth grade has been raised from Rs.600 to Rs.700. The remaining 8 form a new grade, called the fifth. The relief afforded is not calculated to satisfy the recipients or their less fortunate colleagues, when it is remembered that the pay of their predecessors rose from Rs.600 to Rs.850 by annual increments of Rs.30. It appears very hard that, while so many are deprived of promotion, those enjoying higher salaries—Rs.900 and Rs.1,125—should have their pay increased to Rs.1,050 and Rs.1,500 by annual increments of Rs.30 and Rs.75 respectively. To those who have been grievously disappointed it would be no more than just to give Rs.750 after seventeen years' service, and Rs.1,050 after twenty-three years' service, according to the scheme of 1866.

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

LECTURE III.

Dr. Stone: Mr. Vice-President and Gentlemen, I hope I was able to showi n my second lecture the effects of the polarisation which occurs in all electrolytes and in the human body, to an extent not previously measured so far as I know. I also showed the important bearing of these physical effects on the physiological observation of electrotonus. But, before I proceed to the subject of to-day's lecture I have to acknowledge my faults—I have to confess my sins. In the first place, in the skeleton form of Mance's method a minus was omitted between the two terms of the numerator A - B. I will not say whether that was my fault or

Digitized by Google

not, but it certainly led me to describe the formula as one of multiplication. The product divided by the sum is so familiar a formula to electrical workers that the mistake was natural. But the method really is the difference of two quantities—two compound quantities, both of them called A and B, divided by a third compound quantity called C. I understand from Dr. Ord that the mistake was, however, so very obvious that I need not occupy more time in explaining how it arose. Dr. Ord was kind enough to suggest to me that I did not make the demonstration of the two sounds in the induction discharge quite so clear by the telephone as I ought to have done, and, therefore, I propose to do it in another way to-day, and as it were to carry the practice of demonstration, so well known in this college, a step further. I have arranged a contact breaker, and I will ask you to take the telephones whilst I perform the experiment as I think more satisfactorily. I shall make and break so very slowly that what by habit has become easy to me will be easy to you. It was my fault entirely before, being myself so long accustomed to these observations, the tick, tick being a little too close together. [Experiment.] Now it is ticking doubly, but it is distinctly audible, like the tick of a lever watch. That has been made a great physiological point of, but it is reproduced here, without physiological apparatus, without the galvanoscopic frog, entirely by means of the telephone Here I will end my confessions, and I am now enabled to begin the subject of to-day. I have to speak this afternoon of induced currents, and the subject of induced current has been gone over and over again in every text book *ad nauseam*. I do not wish to repeat all that can be read therein. The current of induction is momentary: but it can also occur in the same wire, and when occurring in the same wire it is called the extra current. The current on making is weaker than that of breaking, because the extra current in the first wire antagonises the make and assists the break. A sort of momentum is produced, and an opposition action goes on. Now these induction currents came very early into physiological and therapeutical use. They succeeded, indeed, very soon upon the discovery of electricity, which dates from before the present century, and the reason, I believe, of this is, first, from their obvious effect on the sensory nerves; secondly, from their valuable action on muscles as stimulants; and, thirdly, from the remarkable work done by Duchenne some thirty years ago. Now, I recollect Duchenne well when I was in the hospitals of Paris about 1856, and there cannot be the least doubt that his was a very clumsy and primitive induction coil, with which he accomplished by patient labour a most marvellous work. He isolated several new nervous diseases. He tested the reaction of muscle to stimulants, and he made quite a new era in our knowledge of electrical stimulus. But the current used by him was not specially or specifically electrical. He had a good muscle stimulant. His coil was merely a convenient way of testing the susceptibility of muscle, and it had no great electrical value. This has done some damage to subsequent electrical work because it has been taken for granted that the convenient stimulus which he used in the induction coil had some bearing on electricity. In the higher branches I believe it has none. For testing the contractility of muscle it is still unequalled. It is also most valuable as a means of keeping up irritability of muscle which has damaged by metallic impregnation of lead, or from which by nerve injury all the motor nerve influence has been cut off. But we must recollect that this machine of Duchenne is a muscle stimulant; it is not a nervous stimulant. It is not necessarily an electrical phenomenon at all. No doubt it might be used also, though with more caution, to test sensation. But here individual differences of temperament step in, and the tolerance to induced currents is extremely various in different persons. This has been discounted by the class of people who attend fairs and exhibitions, and who have an enormous machine with a vast amount of bright apparatus on which they ask you, for the remuneration of one penny, to test your strength. All you test in a case like this is your susceptibility to a certain amount of induced current, and this no doubt varies very much. If the points were taken up scientifically, something might be made out of it; but even this is not really an electrical phenomenon. No doubt induced current may go a stage further, and do good service in stimulating even so deep seated a muscle as the diaphragm in asphyxia or in suspended animation. In cases of opium poisoning I believe the induction current should be used, one pole to be over the nape of the neck and the other pole moving about in front of the abdomen, because it will set up respiration when it seems to have been lost. Besides this it is of great value in the lecture room. It is a convenient and effective means of physiological demonstration. But there its use ought to end. Even in physiological research it is unsafe, and I very much regret that some recent and valuable researches as to the localisation of brain functions have been founded on the use of induction currents. And, firstly, for this reason, that there is not only no proof that the current passes through the region included between the poles, but there is very conclusive evidence, I believe, that it diffuses itself widely and irregularly in all directions with enormous differences, according to small differences of conductivity. But, secondly, I may even say it is very doubtful if a current passes through a moist substance like the brain tissue at all. I have to show you that it is possible and probable—I believe that it is true—that it only starts a series of laminated polarities in a bad conductor, which resembles very much the laminated condition of a condenser. For this reason I spoke of the condenser in my syllabus, and although I had withdrawn the term, I think there is something like a condenser action in this laminated, this polarised state, which the opposite currents from an induction coil may produce in a feeble conductor. However, when I speak of induced currents of that kind I mean the currents obtained from an induction coil. You can make induction currents by a totally different method from this, and if they are to be used with any certainty they should be used after another fashion —I mean alternating currents obtained by commutating battery currents. Here you are able to measure the electromotive force of the battery. Now, I had intended to speak of these alternating currents as produced by a tuning fork, but I have found this would pass beyond my limits of time; besides, in the next place, I shall show you presently that it is not necessary further to investigate it, because, as a matter of measurement, it must be thrown aside. But the measure of induction currents is a question of some importance, and of the more importance because, in reading a medical periodical a few months ago, I saw a review which commenced by the general statement that it is impossible to measure induction currents. Now this, strictly speaking, is not true, and I shall proceed next to show you three methods by which induction currents can be be measured—first of all by Hartmann's dynamometer. But it is too delicate to be shown in a lecture room. It is very good indeed in the silence and quiet of the laboratory. It may be briefly described as a galvanometer in which the moving needle has been replaced by a moving coil. The instrument is in very great use in electrical investigations, but it is hopeless to produce any demonstration with it in a lecture like this. I therefore prefer to take the two simpler and rougher modifications, which answer medical purposes better than that—to be used at a distance with the reflected telescopic image of the scale. But I have two here which will answer our purpose, and which are not so difficult to demonstrate. Here is, first, my old dynamometer, which went across the Atlantic with me to the British Association meeting at Montreal, and here is another one, but which, I believe, has not been employed before in this particular way, and in which the whole trouble of having a current through a coil is removed by using a sheet of soft iron. The first I will describe as a coil made of light aluminium wire. Without diminishing the electrical contact the aluminium is a substance which for a given bulk is the largest conductor of electricity. By making an aluminium coil you get a light and moving coil, which will act under our small currents. But even that I have since found can be dispensed with. I do not claim to be the discoverer of it; it was discovered in Italy; but I have made with my own hands an instrument, using a coil from another galvanometer, which will demonstrate this very well. If instead of an aluminium coil through which the current is passing, you take two sheets of ordinary or soft iron, they so rapidly change their polarity that they are equivalent to a coil in which a magnetic force is developed. Two soft iron sheets are mounted here between two coils, and I shall not waste very much time on this experiment, and I will only just turn the handle of the exploder, which produces a moderate induction current in alternating directions—quite tolerable by the human being—so that this is within the range of what we can stand and use. [Experiment.] Now, there I have induced magnetism in these two plates of iron, and I think that will be the dynamometer of the future for medical purposes. It avoids so many complications and difficulties. I will do it once more. [Experiment.] But a far better and more accurate determination can be obtained by that most beautiful instrument, the quadrant electrometer. Now, the quadrant electrometer, like the dynamometer, is far too delicate to attempt to demonstrate with it in a lecture room, but I have made determinations with it, in which I had the valuable assistance of the professors of Cooper's Hill College, and it is the united work of myself, Mr. Gregory, and Prof. Stocker that I shall reproduce here. I have given two formulæ there by which the determination on the electrometer can be made. I do not intend to lay much stress upon it now, but the general principle of it is this—that if the currents are alternating the needle of the Thomson electrometer must be put in communication with one of the quadrants, preferably with one of the quadrants and then the other. The upper diagram is that given by Prof. Adams in his Cantor lectures, and in the other diagram [indicating it] there is the mode of measurement given me by Prof. Hopkinson. Time will not allow me to dwell upon them; but I will give you a *résumé* of certain determinations made in that way with a fine quadrant electrometer at Cooper's Hill. The process we adopted was to compare the deflection obtained on the electrometer, that is the difference of potential with an alternating current with that of a battery of which we knew the force and which we could measure. "In these measures," says Mr. Gregory, writing to me, "the negative pole of the battery was to earth, the positive pole being connected at will to either pair of quadrants, and the needle also at will to either pair, giving four readings for each observation. I give only the means which agree very well." The determinations are ·149, ·151, and ·146 each, which gives a mean ·1486. Using the mean value we worked out that the electromotive would give a deflection of 107, which we got. It came out 38. Then we took the same determination with the same electrometer, with the same constant and batteries, and it came out 107·25. This agrees very well, says Mr. Gregory (I wish they would all agree so well), so that it will be very easy to value the electromotive force corresponding to any deflection by the formula which is made here. We then tried the making and breaking of contacts about ten times a second. The deflection was obviously somewhat low, so that possibly the effect of rapid alternations is to lessen the deflection for the same electromotive force. But observations seem to point to this, that the mean electromotive force developed by the induction coil (and the induction coil we used I shall show you presently) is certainly less than 50 volts, and probably nearer 40. I think we may take it at 40. Of course, this is not the maximum electromotive force. Even the electrometer integrates to a certain extent. But still, this measurement, which I think has not been made before, may be taken as sufficient for all our purposes. I do not think I will occupy more time on this subject. We have made a measurement—and a successful measurement—of the force of an induction coil of the ordinary form, and this, instead of being eight or ten volts, is at least 40, and may go quite up to 50. Now, I want to show you a curious result that comes from using this induced current of from 40 to 50 volts passing in an alternating current through the human body; and here again I shall have recourse to my telephones, for I have discarded the galvan-

Digitized by Google

ometer for the more sensitive and delicate telephone. I shall introduce the human body into the circuit, and I shall use for this purpose Kohlrausch's combined induction coil and meter bridge with the telephones. Now, here the electromotive force which is working it is only four volts—two bichromate batteries—and I will ask you to put a telephone to your ears. I have a quarter of a metre here of platinum silver wire, and a number of fixed resistances, so I will employ a hundred resistances, and then I will employ a thousand, but I am afraid my human patient will not stand it, and when I get balanced you will find that the telephone will cease to speak. [Experiment.] I get 600 ohms against 1,100 given by the constant current. Now, this is very important. The same man whom we tested at the first lecture only shows 600 ohms resistance, whereas to the constant current he shows 1,100, and this is invariably the case, and I believe the observation is absolutely new. Of course, however, the first result of it is that it is clear that this induction current cannot be used for the measurement of human resistance. We lose something there. But, on the other hand, we get physiological facts of very considerable importance, and the explanation of this difference is what I will next proceed to consider. It is susceptible of several explanations. In the first place, the human body, like all imperfect conductors, in all probability is more permeable to high tension than to low tension currents. This occurs in all feeble conductors. I think the effects of these experiments alone fairly prove this, and there are many that you come across in telegraphic work which prove it. Indeed, the diagram we had last time, when we used an E.M.F. of two volts, four volts, six volts, and eight volts, showed a distinct falling of resistance as the E.M.F. was increased. But there is a great deal more than this. It is probable, as I said before, with the rapid intermission, the current does not pass at all, or not fully, until it is met and annulled by the next current in the opposite direction. Thus the body would be like the leaves of a book in a stratified or laminated condition, or more closely like an elastic body transmitting the waves of sound with alternate plates of condensation and rarefaction represented in this case by positive and negative polarities. Now, curiously enough, this comes out from Du Moncel's early and successful experiments. He found that there was inside the charged body something like the leaves of a book. There was the new polarised current obtained at the extremities, and at first giving an opposition current, which soon yielded to the old current which had been established internally. This seems to me to be a proof that the body can take up a series of laminated polarities, and does not transmit these induced currents. There was a long controversy on this subject (which I have not time to go into) in *The Electrician*, in which some good letters were written. I was the starter of the subject, advocating these views, and I was induced by Sprague and Blakesley, who have contributed very valuable illustrations in induced and other currents, to modify my opinions. But there is a third reason which, I think, ought to be considered, and that is, as Dr. Oliver Lodge has suggested to me, that an alternating current ought to show too low a resistance because of the electro-chemical capacity of the body which the current would treat as conductivity—the reciprocal of resistance. If we were to measure the resistance of a perfect condenser with alternating currents it would not come out infinite even if the insulation were as perfect as it could be made. Here, again, was the reason for my putting into the syllabus that there was something like a condenser action in the human body. Lastly comes the fourth point, and, as I believe, there is considerable self-induction. Now, self-induction is a word which involves a great deal of difficulty. It is to be avoided in all induction coils, and in all resistance coils. The possibility of its playing a considerable part in the actions now before us was brought strongly before me only two months ago by a highly suggestive paper by Prof. Hughes read before the Society of Telegraph-Engineers on January 23th of the present year. He gives a very good account, and a very perfect account of what is known of self-induction. Induced or secondary currents in a double circuit were discovered by Faraday in 1831. The phenomenon of self-induction, or an electric current on its own wire, was observed by Henry in 1832, and enlarged upon by Faraday in 1834. He proved that by sending a current through a wire a momentarily induced current in the opposite direction is evoked in its own wire, and also on the cessation of the primary current excitement is induced on the secondary. I will not go further into that now. What I have to note here is that Prof. Hughes makes two different periods—the stable period and the variable period. The ordinary current from the battery is not in itself used—is not tested—until it has got to the stable period, but the induction current is in the variable period. There is some controversy as to the mathematical interpretation of these facts; but my own belief is that in the main they point to a new direction of research which may be utilised by physiologists. He divides the current into stable and variable periods. The continuous current is stable, and the interrupted variable, so that it is in the latter that induction takes place. Prof. Hughes has brought his improved method of investigation forward in place of the time-honoured Neef's hammer, as in Du Reymond's coil. He uses his own invention, the microphone, or, still better, a small contact-breaking clock. This enables the ordinary meter bridge to be used for measuring resistance, and if time allowed me I should show how it works. But you may combine this mode of measurement with Prof. Hughes's sonometer. I have here a simple form of the sonometer, in which the induced coil slides along a bar. As I slide this along the bar I think you will be able to detect the effects of induction. [Experiment.] Now, I am very glad to have been able to show what I believe is a perfectly new experiment, and I will admit that it is somewhat difficult to show. If these coils be set up at measured distances, and an interrupted current passed through the primary coil, the patient, and a known resistance in the secondary circuit on either side of the telephone, good measurements can be obtained. There is a still further modification of the instrument that I do not propose to go into to-day. This is Prof. Hughes's last discovery. He blends together a Wheatstone bridge and a sonometer, by which I hope we shall be able to balance, if it will act, not only resistance but self-induction. I have not been able to make any definite measurements yet. The instrument has only been before the public since January, and this particular instrument, which takes some time to make, has been in my hands only for a fortnight or three weeks, but I think if I cannot give exactly the measurements I can give demonstrations which will enable you to see what it means. But whilst this is being put up I will occupy your time by a few general considerations. I think I have been able to show you that here is a great field for future research — that the whole basis of physiological electricity requires strengthening and re-examining. It is a stately building built by Du Bois-Reymond and many others, of which the foundations are unsafe. Until these are made firm the whole superstructure is in danger. But if, on the other hand, we set to work and strengthen the foundation we shall in the course of the necessary explorations come on many precious discoveries. Already the analogies between the nerve force and this great physical force—electricity—are becoming very strong, and one such, on inhibition, was published in *Nature* by Dr. Lander Brunton. He took up the theory (I hope it may be true) that different lengths of nerve conductors might transmit wave influences at a period such that there should be interference, and so inhibition might occur; and I ventured at the end of my syllabus to place another such attempt to go out into the infinite unknown, by saying that there are many analogies between the condition of the human body and a duplexed Atlantic submarine cable. The curious thing about the submarine cable is that its results are produced at the far end, and that nothing is shown at the near end. How like this are many nervous actions of the human body! When you see these strong analogies you cannot resist the impression that nature must have worked upon one plan, and although we have not found it there must be some link between the two. I do not wish to lay any stress on the duplexed cable other than that it produces on my mind, and it may on yours, a strong feeling that the analogy is too great not to be in a certain sense real, although not yet discovered. And we are coming upon this every day. It is a most desirable thing that we should come upon this, because every connection that can be found between physical facts and that unknown vital region which we have been accustomed to investigate is one step further on the road to truth, one of the mysteries taken out of the unknown and added to the known. I shall conclude by offering a few observations as to what are the hopeful directions of electrical work. I see the therapeutical use of electricity looming before us in the direction of muscular enfeeblement, palsy, and what has been called reflex action. I am not quite certain of its value on the sensory nerves in cases of neuralgia. I mentioned and gave you the details of a case of sciatica, which I have no hesitation in saying was instantly and momentarily cured by a continuous current. I believe it is of great value in neurotic cases, such as locomotor ataxy. It has the power of loosening chemical compounds in the body. Therefore, it follows that it should be an eliminative, and that I am absolutely sure it is, because I have extracted from a fellow creature by electrical action 3 milligrammes of copper. The same thing has been done often and often with mercury. I think that concludes what I have to say on the subject of electricity. But beyond that I have something to say. I have to thank you all. I have had the intelligent support of my colleagues. I have been honoured by the presence of my brother censors, and I have received the greatest kindness from all connected with the college. I have had the patronage besides of men not belonging to the medical profession, like Sir Henry Mance—an honour which I cannot too highly appreciate—and I have enjoyed the careful attention of many of my students. I thank you all sincerely, and I will finish by a well-known formula, thus reviving a time honoured practice of this learned body:—

Dixi quod felix faustumque sit hinc collegio.
Vos omnes Volete et plaudite.

COMPANIES' MEETINGS.

Reuter's Telegram Company (Limited).

The twenty-second ordinary general meeting of the shareholders in this Company was held on the 22nd inst. at the offices, 24, Old Jewry, Colonel James Holland presiding.

The SECRETARY (Mr. Griffiths) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: It is quite unnecessary for me to say that it is matter of very great regret to us, as, no doubt, it is to you, that we have to produce to you a report and balance-sheet without any dividend—for the first time, I may say, in the records and annals of the Company; but those gentlemen who may chance to recollect some of the few remarks I made at the last meeting will probably not be surprised at the fact. I should like just to quote a small portion of my speech this time last year, which to a great extent prefigured what has happened. I stated then:—"If you will turn to the balance-sheet you will find that the receipts have been £3,700 more than last year, which shows that, though the business has not fallen off, on the other hand, the cost of procuring that intelligence has increased by £6,000. It will be, therefore, a serious and anxious duty for us as the engagements now standing with the Press fall in to endeavour to make such fresh agreements as shall satisfy the shareholders that the moderate interest which we look for upon our capital shall be made good in future. It is evident that with war constantly on the horizon the expenses must increase." Well, it was not in

Digitized by Google

our power until a very late period to moderate in any way the agreements with the Press, because those agreements were made for certain fixed definite periods. When that period elapsed we had sundry communications with the various leading newspapers, and the result has been, I am happy to say, that they, seeing the justice and the necessity of the case, have agreed, in future cases of wars or great disturbances, such as to necessitate a very considerable addition to our expenditure, that they will on their part increase the amount of remuneration for our services to an extent which will practically prevent any recurrence of the present rather unhappy experience—that is to say, of no dividend. That is the bright lining—or a portion of the bright lining—to the cloud which is just now hanging over us. When I last year made the remarks which I have just quoted, we had a hope that war-like operations had ceased, or were about to cease, and that, therefore, notwithstanding the heavy expenditure we had incurred without return, we might have a moderate profit at the end of the year; but since then from Khartoum to Burmah has been one unceasing round of war of one kind and another. The Rangoon affair, although a satisfactory matter as respects the interests of the country, has been, as all wars are, a very unsatisfactory one for us, as we had to incur considerable expense in order to be first in the field—as it is our duty to be—our duty to you as well as to the public. We have also had to suffer—as mercantile men generally and the public have had to suffer—from the depreciation in silver. Exchanges have been very unfavourable to us, and our remittances from India have been very considerably "watered." There has also been very considerable mercantile depression, extending for a very considerable period, and we know no more than you when that is likely to end. All we can do is to hope that it may end, and that we may have no more wars—for some months to come, at any rate. Turning to the balance-sheet, there is nothing of any special consequence to note in it. The various items under the heads of "sundry creditors" and "sundry debtors" have all run off. The current expenditure has been a trifle less than that of the preceding year, but the telegrams and agencies—the great item of cost—have been £1,500 more than the very heavy expenditure on the same account in the preceding year. All this is simply to account for the unhappy fact of no dividend; but I am glad to say that it is by no means a hopeless affair. First of all, as I have told you, the Press have come forward very handsomely to meet us in the matter of cost in case of future wars or disturbances, and I am very glad to be able not only to give you this general assurance of brightening prospects, but something beyond. Although we have not yet got our figures as to the receipts for the first quarter of the year, we know that the expenditure on the telegrams for that portion is upwards of £2,000 less than it was in the corresponding period of last year. That is a solid fact, and therefore gives us very justifiable grounds for hoping for much better things. I may further add—which is also *pro tanto* satisfactory—that we have no bad debts. That is all I have got to say with regard to our balance-sheet and report. There are two other matters I wish to allude to. One is the absence of our esteemed colleague Baron de Reuter, who would have been present at this meeting, but unfortunately his ill-health has compelled him to reside for a time abroad. I may say, however, that we are in frequent communication with him, and I am authorised to state that he fully shares in the views which I have set forth, and on the line we have taken. I have also got to remark on an unhappy loss at our Board. Since I met you last year our esteemed and much-respected colleague, Mr. Stopford, has died, and I am sure you will regret his loss very much. Mr. Stopford was one of the original directors along with Sir John Hay and myself—one of the first Directors of the Company, and you cannot be connected for over twenty years with a man without knowing something of his character. We had all learnt to like and esteem Mr. Stopford as a man of business and worth, and an excellent man. I have no further remark to make, and I will now put the motion, which is, "That the report and balance-sheet now presented be received, adopted, and entered on the minutes."

Admiral the Right Hon. Sir J. C. D. HAY, Bart., K.C.B., seconded the motion.

The CHAIRMAN invited discussion, offering to answer any question which might be asked of him; but no one rising to address the meeting, he put the resolution, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. HERBERT DE REUTER (the Managing Director), Admiral Sir John Hay was re-elected to his seat at the Board.

The auditors (Messrs. Quilter, Ball, and Co.) having been re elected, on the motion of Mr. BRADSHAW,

Mr. LOVEDAY proposed a vote of thanks to the Chairman, Directors, and secretary, observing that they had to thank the Board for keeping nothing from them. If the shareholders got no dividend, they got the truth, and he thought when the Chairman had given them a reasonable promise of dividend for the future, they might take that as an earnest of what was to come.

Mr. WOLFF seconded the motion, which was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I have to thank you very much for your kind vote. It is particularly gratifying to us, because we all know, from our own experience and our own feelings, that a meeting where no dividend can be recommended is one that generally rather exasperates the feelings of shareholders, and a kind vote to the Directors is very seldom the result. I repeat my hope and belief that we shall have a better meeting this time next year.

The proceedings then terminated.

TO ELECTRICAL APPARATUS MANUFACTURERS.—EMPLOYMENT WANTED at the above by a Watchmaker. Well acquainted with all kinds of Fine Turning, lathe and hand.—Address, WATCHMAKER, *Electrician* Office.

THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).

NOTICE.—REDUCTION OF TARIFF.

On and after 5th MAY, 1886, the TARIFF between the United Kingdom and all the principal Telegraph Stations in the United States of America and Canada viâ DIRECT CABLE will be SIXPENCE per WORD.

Special arrangements can be made at the General Offices of the Company for the transmission of PRESS MESSAGES at THREEPENCE per WORD.

Complete Tariff will be issued shortly.

J. W. FULLER, Secretary and Traffic Manager.

General Offices, 50, Old Broad-street, London, E.C.

J. H. GREENHILL,

(NEW) KING ST., BELFAST, IRELAND.

ELECTRIC LIGHT ENGINEER.

Manufacturer of Dynamo Machines with Wrought or Cast Iron Magnets for Arc or Incandescent Lighting, and of a capacity from 5 to 500 lamps of 20 candle power, nominal.

Complete Installations contracted for on Moderate Terms.

Reference can be given to firms who have had permanent Installations erected and constantly at work for the last four years.

THE MACHINES ARE OF VERY HIGH EFFICIENCY.

NALDER BROS.,

Instrument Makers, Electricians, and General Electrical and Mechanical Engineers,

Office: 8, Victoria Chambers, WESTMINSTER, S.W.

Steam Factory, Brent Electric Works, The Ham, Brentford. Laboratory, The Butts, Brentford.

Manufacturers of Resistance Boxes, Wheatstone Bridges, Thomson and other Galvanometers, Lampstands and Scales, Electrometers, Condensers, Keys, and Electrical Standards of every description.

VOLTMETERS and CURRENT INDICATORS.

Cathetometers, Micrometers, Bar Callipers, and all descriptions of Electrical, Physical, and Mathematical Instruments. Experimental work undertaken. Chloride of Silver and other Batteries. Switch Boards, Switches, and Electric Light Fittings.

Instrument Cabinet Work.

Complete Installations of Electric Light undertaken. Engines, Dynamos, Motors and Lamps supplied.

Digitized by Google

NOTES.

British Guiana. — The cable between Trinidad and Demerara, which was interrupted in March last, is now restored.

The West Coast of America Telegraph Company.—The gross earnings of this company for the month ending April 30th were £3,225.

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 30th ult. amounted to £3,055.

Eastern Telegraph Company.—The traffic receipts of this company for April amounted to £47,611, against £63,085 in the corresponding period of 1885.

Direct Spanish Telegraph Company.—The estimated traffic receipts of this company for the month of April are £1,597, against £1,510 in the corresponding period of last year.

Another Telephone Discoverer.—Dr. Cushman claims that he discovered the telephone in 1851 whilst experimenting with lightning arrestors upon a line he was engaged in building from Racine to Beloit.

Great Northern Telegraph Company.—The receipts in April were £19,800, and the receipts for the period of January to the 30th April, £78,480; for the corresponding months in 1885 £89,200, and 1884 £81,640.

The Eastern Extension, Australasia, and China Telegraph Company.—The traffic receipts of this company for the month of April amounted to £34,292, and to £41,233 in the corresponding period of 1885.

Reduction of Rates.—The Eastern Telegraph Company notifies that, by arrangement with the Brazilian Submarine Telegraph Company, the rates to South America are now materially reduced. Particulars of the reductions, which vary from 2s. to 3s. per word, are given in our advertisement columns.

Lighting Canals by Electricity.—The Canadian Government has decided to illuminate the Lachline Canal by means of Edison's incandescent light. It is expected that if this proves a success the Welland and other canals will be lighted on the same principle.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended 30th ult. were £2,551, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

The Society of Telegraph-Engineers.—The next meeting will be held at the Institution of Civil Engineers, 25, Great George-street, S.W., on Thursday, 13th inst., when a paper "On Long Distance Telephony," will be read by Mr. W. H. Preece, F.R.S., past president.

The West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ended 30th ult. are £2,435, as compared with £3,857 in the corresponding period of 1885. The January receipts, estimated at £5,484, realised £5,477.

Electric Light in Palermo.—The *Economista d'Italia* of the 1st inst. announces the formation of an electric light company ("Societá Thomson Houston") in Palermo, with a capital of 500,000 lire, say £20,000. Subscriptions were invited between the 3rd and 5th inst. for an issue of 500 shares of 250 lire, say £5,000.

Liverpool Exhibition.—One of the courts in this exhibition, which is to be opened by Her Majesty on Tuesday next, is set apart exclusively for a display of various electrical apparatus. From the lantern at the top of the model of the Eddystone lighthouse an electric light of great power will be visible for miles around.

The Newry and Dessbrook Electric Tramway.—The new line of electric tramway, three miles long, between Newry and Dessbrook, has just been taken over from the contractor by the company. During the six months it has been working, 10,000 miles have been run, and 43,000 passengers and 8,000 tons of goods have been carried.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this company during the month of April was 3,961, estimated to produce £3,300, against 4,319 messages, producing £3,886, in the corresponding month of last year. The traffic receipts for the month of January, estimated at £2,850, realised £2,891.

Photography by Electricity.—It is the opinion of M. Ottomar Volkmer, who has recently been writing on the subject in *Electricité*, that as soon as electricians can supply the electric light at anything like a reasonable price, it will be largely used in photographic studios in preference to daylight. We may supplement this by saying that in England it is being largely used by photographers.

Domestic Electric Lighting.—Recently the chairman of the Maxim-Weston Electric Light Company (Mr. Hugh Watt, M.P.) gave a reception at his private residence in the St. George's-road, S.W. A select company of scientific men were present, who, it said, expressed themselves greatly pleased at the success of the installation. A Weston dynamo was used, power being supplied by an Otto gas engine, both of which were placed in a wooden shed at the back of the house.

The Electric Light in Holland.—At Kinderdyk, near Rotterdam, the electric light has been introduced. Fourteen lamps have been placed in the principal street, and a few shopkeepers have adopted the system. The light is kept up from sunset till midnight, the dynamos being worked by two steam engines. The price charged per year per lamp of 16 candles is £1. 1s. 5d. where only one is used; for two, £1. 0s. 2d.; for five, 19s.; for ten, 18s. 4d.; and for twenty, 17s. 8d. each. The life of a lamp is estimated at 1,000 hours, and when it is exhausted it may be replaced for 3s. 9d.

Electric Music.—M. Semmola, says the *Electrical World*, a German investigator, one of the many who have experimented in this direction, has succeeded in producing musical tones from a metal plate by electrifying it intermittently from an induction machine. The plate is supported on an ebonite funnel and is a millimetre in thickness. The terminals of the induction machine are connected to opposite sides of the plates by wires, and the path of the current is interrupted so that sparks strike across. The plate then begins to sound, and it continues to sound even if a Geissler tube or a lead wire is interposed in the break.

Large Dynamo.—The Brush Electric Company, of Cleveland, it is said, are building the largest dynamo in the world. It will be 12 or 13ft. long, 5½ft. wide, and weigh ten tons. It will give a current of 122,500 amperes; number of watts, 245,000. In other words, it will be four times the size and capacity of the "Jumbo" machine exhibited by Edison at the Electrical Exposition at Philadelphia. The latter was adequate to the task of running 5,000 sixteen candle-power incandescent lights. This monster machine of the Brush Company will be

Digitized by Google

shipped to Lockport, N.Y., and be used for the smelting of "aluminium." Five hundred horse-power will be required to drive it, which will be furnished by water, with the aid of turbine wheels.

AN ELECTRIC LAUNCH.—On Saturday last people passing between Charing Cross and Westminster Piers might have witnessed if not a novel at least an interesting experiment on the river with a small electric launch built by Messrs. Yarrow, and fitted with motors supplied by Mr. A. Reckenzaun. The little vessel, which carried its full complement of passengers, sped through the water with amazing rapidity, and caused no little surprise to travellers on the passing steamboats, who, of course, could see no visible means by which the launch was propelled. The speed attained was between nine and ten miles an hour with, and a little over seven against, the tide. We understand that Mr. Reckenzaun meditates a trip across the Channel at an early date.

ELECTRIC LIGHTING.—We are glad to hear that Messrs. B. Verity and Sons have obtained the contract for lighting the new Holloway College at Egham. Most of our readers know that the late Mr. Holloway built and endowed this college, and that it is one of the most ornate structures in the land, and, if anywhere, the electric light should here show to the greatest advantage. We have no doubt that the experience which Messrs. Verity and Sons have gained in designing the fittings at such places as the Holborn Restaurant will enable them to design most appropriate fittings for the new college. The installation will consist of some 500 16 candle-power incandescent lamps, and the current will be supplied by two Edison dynamos of the new form, either of which will be, if required, capable of supplying the whole of these lamps.

A LONG DISTANCE TELEPHONE.—Interesting experiments are still being made with the object of ascertaining whether persons provided with the telephone in Paris can correspond directly with telephone holders at Rheims. The distance separating Paris from Rheims is 172 kilometres, but, including the length of the subterranean telephonic wires, the distance is 220 kilometres. The lines serving for these experiments were two ordinary telegraph wires, one of which was the Rheims wire, and the other the Berlin wire, which had been adapted to the public telephonic service organised between Paris and Rheims by means of M. Van Rysselberghe's anti-inductive system. This system permits of telegraphic and telephonic despatches being simultaneously transmitted by the same wires without the slightest confusion, so that while telephoning was going on between Paris and Rheims the same wires were traversed by telegraphic despatches exchanged between Paris, Rheims, and Berlin. So far the experiments have proved very successful.

ANOTHER FRENCH ATLANTIC CABLE. — The Paris correspondent of the *Daily News*, telegraphing on Wednesday, says: M. Granet, the Minister of Posts and Telegraphs, has granted a charter to a French company for laying a cable between Brest and New York, *viâ* Guadeloupe. The authorisation, to become final, must, however, be submitted for approval to the Chambers as soon as they meet. All the directors are French, and it has been stipulated that the cable is to be manufactured in France and laid by French vessels. An important clause in the contract is that the State will guarantee a certain interest on the capital. It is apparent from the above that powerful influences have been at work to obtain this agreement. Cable industry cannot be well acclimatised in France, even with the tenderest nursing. The Government was obliged to order the new Senegal and Tonquin cables in England. M. Menier is the largest French cable manufacturer, but his business is relatively small. Is is not said what line the company would take with regard to eventual "pooling" arrangements of the other companies.

ELECTRIC LIGHTING.—The electric lighting at the Duke of Newcastle's estate at Clumber, referred to in our Notes of last week, has been carried out by Messrs. Blakey, Emmott, and Co., of Halifax. The large ball room which accommodates six hundred guests has been lit by the incandescent light, distributed over some fourteen fine chandeliers and a number of side brackets, the drawing room, card rooms, &c., being also similarly illuminated. The machines for generating electricity for these lights consist of three Blakey-Emmott dynamos, driven by one of Marshall's engines. Around the mansion and at the temporary stables (which afford accommodation for three hundred horses) the arc light is employed, Pilsen lamps of 2,000 candle-power being worked by dynamos made by the firm named. On the top of the mansion a powerful search light, capable of being directed to any part of the very extensive estate, is provided.—The *Sheffield Telegraph* has an amusing note upon what it terms a narrow escape from a great calamity. We are told that a "crystal bracket, which held an incandescent lamp, had broken, and the liberated flame, in swiftly lengthening tongues of fire, was licking the loop of lace around the mirror." At any rate Clumber was saved by two gentlemen with cool heads. What have Messrs. Blakey, Emmott and Co., to say to this?

CITY GUILDS.—We understand that Prof. Ayrton will, during May, continue his course of lectures on "Some of the Industrial Applications of Electricity." The first two lectures, on May 14th and 21st, will be on the "Electric Transmission of Power," and the following is an abstract of the proposed scheme of treatment:—"Waste of power in the conductors. Advantages and disadvantages of the parallel system of supplying electric power. Economy effected by the use of the series, or the parallel-series system. Most economical size of conductors. Heating of conductors. Uniform potential difference, or uniform current, along the mains. Use of accumulators, secondary generators, and motor dynamos in electric transmission of power. Practical results already obtained with electric transmission. Comparison of electric with hydraulic and wire rope transmission of power." On May 28th the lecture will be on "Electric Locomotion," according to the following scheme: "Tramcars carrying a store of electric energy. Electric launches. Methods of conveying electric power to moving vehicles. Electric, steam, horse, and wire-rope traction. Absolute blocking with electric railways. Telpherage. Probable future developments in the applications of electricity." These will be followed by other lectures on the probable future developments in the application of electricity.

THE MEXICAN TELEGRAPH SERVICE.—In his Presidential Address to the Mexican Congress Señor Diaz referred to important changes in the organisation of the telegraph service, which, he said, had been carried out with considerable economy to the State, and without any detriment to the service. Enumerating briefly the nature of the reforms, he stated that of a total length of 21,000 kilometres of lines only a portion of them were of general utility. As a large part was of local interest the working of such lines has been ceded to the various States for a limited time and on favourable contracts, a moderate amount being allowed them for expenses of conservation. Twenty such contracts for the cession of such lines have so far been concluded, the expenses of maintaining 5,000 kilometres of wires and the service of ninety-three offices having thereby been saved. Fifteen other offices which were not necessary have, he said, also been closed, besides other

Digitized by Google

economies. Instead of crippling the telegraph service, he stated that the new reforms had resulted in a notable improvement in the facilities of communication between the capital and the provincial towns, the ports, and the important stations on the frontier. He stated, however, that the new changes had necessitated the immediate repair of most of the lines which were in a bad condition, and this had occasioned an outlay which had been reduced to the smallest dimensions compatible with efficiency.

Electric Light for Madrid.—We referred a week or two ago to a contention between the Madrid Gas Company and the consumers of gas in that city. The quality being considered bad and the price (about 4½d. per cubit metre) excessively dear, on the 21st April a meeting was held to settle definitely this question, which has been more or less before the public ever since the year 1878. According to the *Comercio Espaniol*, which gives a full account of the proceedings, an amendment to restrict the use of gas was lost, and a proposal to abstain from the use of gas from the 1st July next was carried unanimously, the committee having reported that all attempts to arrive at an understanding with the company by friendly means had failed. We learn from the *Imparcial* that the committee of the Madrid Mercantile Club, which is arranging the matter in dispute, met again on the 27th ultimo to consider several proposals that had been received in reply to the invitation referred to in our former note. It was decided to publicly test the various methods as soon as possible, and also to wait upon the Alcalde of Madrid, to learn upon what conditions arrangements might be entered into for the use of the electric light. The *Dia* of the 1st instant now states that on the preceding day a deputation waited upon the Alcalde and informed him that from the 1st July next the traders and merchants will discontinue entirely the use of gas, and that from that date the shops and business establishments will be lighted by electric light.

Leeds and the Electric Lighting Bills.—At a recent joint meeting of the Parliamentary and Electric Lighting Committees of the Leeds Corporation, Alderman Emsley presiding, the question of the Electric Lighting Bills, which have been referred to a Select Committee of the House of Lords was discussed. The town clerk, Sir George Morrison, reported as to the action taken by the Association of Municipal Corporations with regard to the Bills, and mentioned that a committee, consisting of representatives of Liverpool, Manchester, Birmingham, Leeds, Nottingham, Sheffield, and Blackburn, had been appointed to deal with the questions affecting Corporations which would arise before the Select Committee. That Committee is appointed to meet on the 10th of May, and it is expected that evidence will first be taken from representatives of the electric lighting companies, and that the committee will sit two days in each week. A deputation to represent the Corporation of Leeds was appointed, consisting of the mayor (Alderman Gaunt), Alderman Emsley (chairman of the Parliamentary Committee), Councillor W. H. Lee Hardwick (chairman of the Electric Lighting Committee), with the town clerk and the borough engineer. It was arranged that the chairman (Alderman Emsley) should bring the Electric Lighting Bills before the next meeting of the council, with a view to the council being asked to petition in favour of the Government Bill, which has been introduced by Lord Houghton.

Alkali Cells.—In a paper in the *Centralblatt für Electrotechnik* (No. 9, 1886) on the "Alkali Element of A. Dun," it is mentioned that this element possesses an E.M.F. which is about as high as that of a Bunsen at the commencement, though it falls off to 1 volt after about half an hour, if the resistance is small, and there remains. But it recovers its E.M.F. after a certain period of rest. This falling off, moreover, is not manifest if the resistance is high, because then diffusion has time to act. The author says, hitherto whenever very powerful, and at the same time time constant cells were required, recourse was usually had to the Bunsen. But, with its good qualities of great E.M.F. and constancy together with small internal resistance, it has the three defects, that the chemical action goes on when the circuit is broken, that it gives out noxious vapours, and that keeping it in working order is both troublesome and expensive. The alkali (or potash) element of Dun is free from all these defects. The negative electrode is a hollow carbon cylinder to which a carbon bottom is left, and the positive electrode is a zinc cylinder. Two thirds of the interior of the carbon cylinder are filled with small pieces of carbon on which is poured acid and permanganate of potash. Two gutta-percha rings prevent contact between the zinc and copper cylinders. It is filled with alkaline solution, which is replenished by putting lumps of caustic potash to dissolve in the glass vessel and carbon cylinder. When the circuit is broken this cell uses no material, whence it may always stand ready for use. The amount of zinc used is exactly proportional to the amount of electricity passed in the circuit. The element is absolutely without smell. It is cheaper to work than a Bunsen element, and it may be used in the neighbourhood of polished metal articles without danger.

The Iron-clad Oath.—In the third annual report just received from the "Bureau of Statistics of Labour," for the State of New York, we find reference made to a document which seems pretty common in America, which is said to generally assume the shape of an agreement to abide by and observe all rules and regulations promulgated by the employers. A violation of any of these rules often subjects the offender not only to the loss of the situation, but also the loss of whatever money may be retained. A specimen of this agreement—which is known among the workmen of the States as the "Iron-clad Oath," as used by the Western Union Telegraph Company—is given on page 587 of the report, and is as follows :—

Western Union Iron-clad Oath.

I .... of .... in consideration of my present re-employment by the Western Union Telegraph Company, hereby promise and agree to and with the said company that I will forthwith abandon any and all membership, connection, or affiliation with any organisation or society, whether secret or open, which in anywise attempts to regulate the conditions of my services or the payment therefor while in the employment now undertaken. I hereby further agree that I will, while in the employ of said company, render good and faithful service to the best of my ability, and will not in anywise renew or re-enter upon any relations or membership whatsoever in or with any such organisation or society.

Dated .... 1883.

Signed ....

Address .... (Seal).

Accepted for the Western Union Telegraph Company.

.... superintendent.

It will be seen that this high-sounding agreement is simply a rather strong-worded agreement not to belong to a union, and to do good service to the employers.

German Edison Company.—We have received an account of the last year's undertakings of this company. The directors say that during this, their third year of business, they have made progress both technically and commercially. They found the demand for electric lighting increase as the installations increased. The severity of the struggle with the gas companies has decreased, and they hope before long that an

Digitized by Google

arrangement will be brought about which will unite their common interests. In a few cases they have given in, where competition would have lowered the price below what was necessary to bring them a fair profit. Last year they installed 129 machines for about 22,000 incandescent lamps, and about 500 arc lamps, thus exceeding their performances of the preceding year. They have been occupied principally with the construction of central station work, while other firms have undertaken isolated plants. The company has had the electric lighting of the German theatres almost entirely in their hands, and is to have that of the Friedrich-Wilhelm University in Berlin. They have introduced their arc lamps with great advantage in conjunction with the incandescent lamps. Besides the construction of lamps they also manufacture electrical apparatus and instruments. The rooms of the house at 85, Friedrichstrasse, with the exception of the ground floor, are devoted to the exhibition of electrical apparatus. They have been during the past year in the full enjoyment of all the Edison patents, and of such Maxim and Weston patents as have been acquired and found of service. They have taken out patents to protect their new arc lamps, and also to secure themselves in the use of other inventions. The claim of nullity made by the Swan Company against one of the fundamental Edison patents has been dismissed by the Imperial Patent Office. The Swan Company has also been prevented from selling Swan lamps as infringing an Edison patent by a modification which has been pronounced immaterial.

Electric Light and Telephone Wires in Madrid.—The Madrid papers have lately been discussing alleged defects of the telephone service in that city, one of which was said to be the irregularities caused by the induction from the wires of the electric light which run in close proximity. Not only have the telephonic communications been rendered difficult by the induction, but, according to the *Dia*, accidents have occurred which might have been attended with very serious results, owing to the fact that the wires of the electric light are carried overhead without proper arrangements for insulation. The Madrid papers we have referred to considered the matter sufficiently grave to warrant the special attention of the Telegraph Department, and the interference of the civil authorities with a view to the wires being placed below ground. In reply to the complaints of the *Dia* the director of the "Sociedad Matrileuse de Electricidad" wrote to that paper denying that the electric light wires were insufficiently protected at any point where a contact with the telephone wires was possible. He further asserted that the electric current is conducted below the telephone lines, that the irregularities in the telephonic service must be due to defective instruments and polarisation, and that a breakage of the electric light wires could not result in the alarming state of things alleged in the press. The *Dia*, in answer to this communication, affirms, on the authority of those charged with the installation, that the electric light conductors are unprotected throughout two-thirds of their length, though recently some protection has been afforded at the points where the wires cross each other, and then proceeds to give a detailed list of mishaps that have occurred through the breakages referred to, some of which, it states, have completely destroyed the telephone, the apparatus being carbonised, and some of the screws fused by the current. The *Dia* professes to speak entirely in the public interest, and without *animus*; but it implies that the existence of a formal concession in favour of the Electric Lighting Company in Madrid is questioned by many.

Tungsten and Iron Alloys.—The following investigation, says *Van Nostrand's Magazine*, was made with a view of determining the chemical constitution of the compounds of iron and tungsten, employed in steel making. An alloy of the specific gravity 9·31, containing iron 68·4, tungsten 28·2, and carbon 1·9 per cent., was closely powdered and boiled in hydrochloric acid until the evolution of hydrogen ceased, when the crystalline powder adhering to the surface of the fragments was rubbed off. The metallic powder obtained from several repetitions of the above operation was boiled for several hours in hydrochloric acid, and finally washed with water, boiling potash lye, alcohol, and ether, and heated to redness in a current of hydrogen. The result was about 40 per cent. of metallic residue made up of two alloys, separable by the magnet, while scarcely a trace of tungsten was dissolved. The larger part of this residue—fully 90 per cent.—consisted of light steel-grey grains, perfectly unmagnetic, which are well-formed octahedral crystals, sufficiently hard to scratch glass, but so brittle as to be easily rubbed to powder in an agate mortar. They contain iron from 24 to 31, tungsten 69 to 83, and carbon 1·4 to 1·6 per cent. When heated in the air the powder burns with a glimmering light to a brown, non-magnetic product, which, when heated in hydrogen, is reduced to tungsten iron, the crystals preserving their form. No iron is extracted by boiling hydrochloric acid. In order to compare the behaviour of this iron alloy with those with other metals, a perfectly unmagnetic ferro-manganese, containing iron 35, manganese 57·6, and combined carbon 5·87 per cent., was powdered, and oxidised by heating in the air. This was attended with the production of magnetic oxide of iron rendering the whole of the powder magnetic, and after reduction in hydrogen, metallic iron could be separated by the same means. The effect of tungsten in modifying the chemical properties of iron when diffused through it is very marked. This is the particular alloy under examination was found to be completely unaffected by a solution of chloride of copper. From their microscopic characters, as well as their low specific gravity—3·688—it is evident that the crystals, in spite of their compact appearance, are actually hollow forms enclosing gases. The magnetic portion of the residue is a blackish grey metallic powder, without distinct crystalline character. It contains iron 68·1, tungsten 27·7, and carbon 4·1 per cent. When heated in air it burns, augmenting about 80 per cent. in weight, and remains magnetic. By heating in hydrogen, a tungsten—iron compound—is reproduced, which readily gives up iron by digestion with hydrochloric acid. The same alloys were obtained by boiling hydrochloric acid from a pig iron, containing 23·5 per cent. of tungsten; but the proportion of the magnetic uncrystalline compound is larger than that of the harder tungsten crystals. A highly carburized tungsten steel, containing tungsten 11, manganese 1·49, and carbon 2·15 per cent., gave, on solution in hydrochloric acid, 13·1 per cent. of residue in the form of a fine unmagnetic powder similar in composition to the crystals previously described, while a soft steel, containing tungsten when digested with dilute acid, only left traces of iron containing tungsten. The general conclusion drawn from these experiments is, that tungsten is not actually alloyed with the iron, but exists essentially in a free state diffused through the mass of the softer metal, and preserving its own characteristic properties. The most notable of these, namely, low specific volume, accounts for the circumstance that, in order to produce very hard steel by tungsten, it must be used in considerable quantity, in which respect it is in marked contrast to other hardening agents, such as carbon and phosphorus, which form chemical combinations with iron.

ELECTRICITY IN 1885.—Dr. W. H. Wahl, in his summary of engineering and industrial progress, made as secretary of the Franklin Institute, says:—"In the field of electricity the past year may record no startling discovery, although substantial advances in certain directions were made. In the department of telegraphy, the Phelps induction system is undoubtedly the most important invention brought out during the past year. This system renders it possible to telegraph to and from a railway train travelling at the highest speed, and it is reasonable to suppose that when its capabilities shall have been fully developed in practice, it will contribute materially to the safety of railway travel. The Harlem River branch of the New York, New Haven, and Hartford Railroad has been equipped with the Phelps apparatus since the early part of the past year, and experts agree in the opinion that its practical working is satisfactory. The year also witnessed substantial progress in perfecting and introducing the Delany synchronous-multiplex system, the Baltimore and Ohio Telegraph Company having placed New York, Philadelphia, and Baltimore in connection by this system. The inventor has likewise made considerable progress in his attempts to adapt the system to the transmission of fac-simile despatches. In telephony, there is little of note to record. . . . In the department of electric lighting, the most noteworthy contribution of the past year was the publication of the results of the tests of the efficiency and life-duration of incandescent lamps, and of the efficiency of dynamo-electric machines, made under the direction of the Franklin Institute. These tests have been pronounced by very competent authority to be more reliable and complete than anything that has yet appeared in any part of the world in relation to the subject under discussion. They demonstrated that decided improvements have been made in the construction of incandescent lamps by which their efficiency and life-duration have been notably increased; and, in respect to the dynamo-electric machine, that this has reached so high an efficiency that but little margin for improvement remains. . . . In the electric transmission of power, the progress of the past year was somewhat more positive. Electric motors for railways have been experimentally tested in a number of American cities—New York, Philadelphia, Baltimore, Cleveland, and elsewhere—the trials of the Daft system of electric locomotion on the elevated railways of New York, and in Baltimore, having attracted wide-spread attention. The New York expements do not appear to have been followed by any direct results. In Baltimore, however, the Daft system has been in actual operation since September 1, 1885, on one of the suburban lines of surface railroad (the Baltimore and Hampden Railway). This road was originally a horse railway, and is a feeder of one of the principal lines of street railway in that city. It is about two miles long. Two Daft motors are in use, each rated at 10 horse-power, and regular hourly trips are made from one terminus to the other. The system is reported to be working satisfactorily. In Cleveland, on the other hand, where the first experimental trials with the electric railway in this country were made, the latest accounts report that the electric system has been abandoned. . . . It is, however, in the department of electro-metallurgy that the most signal advance was achieved during the past year. The invention here refered to is that of the Cowles Brothers, of Cleveland, Ohio. These gentlemen have succeeded in constructing a smelting furnace in which the intense heat of the voltaic arc is applied far more efficiently than has heretofore been found possible, and with which they have succeeded in easily effecting the reduction of the most refractory substances. . . ."

TELEPHONY.—M. Rothen has given in the last number of the *Journal Télégraphique* the following statistics relating to telephony:—

Towns.	No. of Subscribers.	Population.	Population per Subscriber.	Subscription in Francs.
Italy.				
Rome	2,054	300,000	146	174
Milan	925	419,787	454	184

CORRESPONDENCE.

SELF-INDUCTION OF WIRES.—II.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Not having had an opportunity of revising my letter under the above title on p. 471, April 23, I must correct the following typographical errors. The word "equally," in the 4th line of the 4th paragraph, and also in the 5th line from the end of the 6th paragraph, should be "exactly." The date in the 8th paragraph, where, so far as I remember, I left a blank, should be Jan. 10, 1885, p. 180.

I did not expect to return to the subject, and do so because Prof. Hughes has apparently misunderstood my statements. On p. 495, April 30, he says:—Mr. Oliver Heaviside points out that upon a close examination it will be found that all the effects which I have described are well known to mathematicians, and consequently old." A regard for accuracy compels me to point out that I did not make the statement he credits me with; nor, to avoid any hypercriticism, is the above a correct summary of the many things that I pointed out.

I said, "The discoveries I looked for vanished, for the most part, into thin air. They became well-known facts when put into common language." Observe here my "for the most part" as against Prof. Hughes's "all"; and that I said not a word about mathematicians in the whole letter. An immediate consequence of my statement is another, namely, that some, although a minority, of the results were not well known. There is a material difference between what I said and what Prof. Hughes makes me say. In another place I said that I had "failed to find any departure from the known laws of electromagnetism," and then proceeded to give my reasons for it. This statement includes the well-known facts as well as those which are not well known.

It may be as well that I should illustrate the difference between well-known facts and those that are less known, or only known theoretically. The influence of the form of a thin wire (a linear conductor), and of its length, diameter, conductivity, and inductivity on the phenomena of self-induction is well known. The various relations involved form the A B C of the subject. So are the effects of concentration of the current, and of dividing it, or spreading it out in strips, well known. There is another influence that is well known, that is scarcely touched upon by Prof. Hughes. The self-induction depends upon the distribution of inductivity, that is, in another form, of inductively magnetisable matter, outside the current, as well as in it, in a manner which is quite definite when the magnetic properties of the matter are known.

It is not to be inferred that verifications of well-known facts are of no value—that depends upon circumstances. To be of any use, we must know what we are measuring and verifying. The theory of self and mutual induction in linear circuits is almost a branch of pure mathematics, so simply are the quantities related, and so exactly. It furnishes a most remarkable example of the dependence of complex phenomena on a very small number of independent variables, by ignoring minute dielectric phenomena. In getting verifications, then, it is first necessary to employ a correct method (I have elsewhere, April 30, p. 489, shown the approximate character of Prof. Hughes's method of balancing, and pointed out exact methods). Next, it is necessary to put results in terms of the quantities in the electro-magnetic theory which is founded upon the well-known facts; how else can we know what we are doing, and see how near our verifications go?

Coming now to results that are not well known, there is the thick wire effect, depending on size, conductivity, inductivity, place of return current, &c. This is, in my opinion, the really important part of Prof. Hughes's researches, as it, in some respects, goes beyond what was already experimentally known. Having been, so far as I know, the first to correctly describe (*Electrician*, Jan. 10, 1885, p. 180) the way the current rises in a wire, viz., by diffusion from its boundary, and the consequent approximation, under certain circumstances, to mere surface conduction; and believing Prof. Hughes's researches to furnish experimental verifications of my views, it will be readily understood that I am specially interested in this effect; and I can (in anticipation) return thanks to Prof. Hughes for accurate measures of the same, expressed in an intelligible form, to render a comparison with theory possible if it be practicable. (I send with this a first instalment of my old core investigations applied to a round wire with the current longitudinal.)*

There are also intermediate matters where one can hardly be said to be either making verifications, except roughly, or discoveries; for instance, the self-induction of an iron wire coil. Theory indicates in the plainest manner that the self-induction coefficient will be a much smaller multiple of that of a similar copper wire coil than if the wires were straightened. Magnetic circuits are now getting quite popularly understood, by reason of the commercial importance of the dynamo. But there is really no practical way of carrying out the theory completely, as the mathematical difficulties are so great. Hence, actual measurements of the precise amounts in various cases of magnetic circuits are of value, if they be accompanied by the data necessary for comparisons.

There is, however, this little difficulty in the way when transient currents are employed. Iron, by reason of its high inductivity, is pre-eminently suited for showing the thick wire effect. We may not, therefore, be always measuring what we want, but something else.—Yours, &c.

May 2, 1886. OLIVER HEAVISIDE.

DUPLEX CUT-OUTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Mr. W. Granger's letter in your last issue, we would beg to say that our specification has been drawn with a full knowledge of all and everything claimed in Mr. K. W. Hedges's specifications of 1881, 1882, 1883, and 1884, and we fail to see any point in which he anticipates our own claims. Our memory does not carry us back to all Mr. Hedges' excellent productions exhibited at the Crystal Palace Exhibition, and failing anything published on the subject, we must plead ignorance as our excuse, *if any is needed*. As you, sir, are doubtless aware, from the specification which we furnished to you, there are many points in our invention which did not and could not appear in the limited space at your disposal for noticing our instrument, but which we thought would (as you so lucidly expressed it) explain themselves.

We have written to Mr. Granger asking for an interview, when we shall be happy to point out to him what are the essential features and claims of our invention, and would ask other subscribers who may feel interested in the subject to either favour us with a call to inspect the "Cut-out," or to consult our specification, No. 14,741 of 1885, which may be found, of course, in the various libraries of the Patent Office.—Yours, &c., BAILY AND GRUNDY.

Amberley Works, Amberley-road, Paddington, W.,
May 5, 1886.

A CLAIM OF PRIORITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You have heard of Mr. Edison's wonderful discovery of induction telegraphy, and his recent successful experiments in telegraphing from moving railway trains. The newspapers, both of America and Europe, have had much to say of this new electrical marvel. It will be interesting, therefore, to know that Mr. Edison has no real claim to this discovery. He has simply applied another man's patent. William L. Silvey, a young mechanic of Cincinnati, invented the induction telegraph at Castleton, Indiana, nearly five years ago. His patent on the invention bears date July 12, 1881. At the time of making this discovery Mr. Silvey was but nineteen years old. He had no means or influential friends, and was unable to interest anyone in the device. The apparatus was given a test at Indianapolis, but it was regarded then somewhat as a scientific toy without a future. Since Mr. Edison's experiments the commercial value of the device is recognised,

* We hope to give this in our next number.

Digitized by Google

although these experiments are no more satisfactory in a scientific point of view than those made by the youthful inventor five years ago. I had the pleasure of meeting Mr. Silvey recently, and found him a modest, industrious young man. He was employed at Lane and Bodley's machine shop, where he was building an electric light dynamo, under his own patent, for the firm.

Noting the advantages of the induction telegraphy over the old system Mr. Silvey said: "There are many advantages. With a small battery we can telegraph long distances. With two quart cups of battery I could easily send a message through a resistance equal to 600 miles of telegraph wire, and it would be produced as loud as any Morse alphabet ever sounded. It would require about 600 cups of battery to send a message the same distance with the Morse sounder and key. Another use would be in sending press despatches. A single operator could have the induction coil of his instrument wound with a number of coils of wire, and by connecting a line with each coil he could send 50 or even 100 messages in as many ways at once. In the telegraph business of railways it would be of incalculable advantage, as may readily be seen. Telegraphing from moving trains is a great achievement, but I believe induction will soon be adopted to purposes of far greater importance to commerce and industry.—Yours, &c., R. W.

Cincinnatti, Ohio, April 19.

ELECTRICITY *VERSUS* HEAT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Thanks for your having published my three letters containing particulars of experiments which prove that electricity and heat are two independent elements.

There is another fact bearing on this subject which is of much practical importance to those who are interested in the passage of electricity through wires. The published writings of the late Mr. Sabine show that in 1883 he had discovered that when a wire was part coated with india rubber and part left bare, and on a current of electricity being passed through this wire, the part coated with india rubber was 25 per cent. cooler than the uncoated part in contact with the air. A Mr. White has recently made similar experiments in America, and it is alleged that he found that when a wire of 65 mils. was part coated with a covering of 285 mils., and a current of electricity passed through this wire, the uncoated part became three times hotter than the coated part. Now every electrician will admit that a wire with a coating of 285 mils. of good insulating material should retain within it more perfectly the current of electricity than the other part of the same wire which was exposed to the air. This being admitted, it becomes manifest that the source of the heat cannot be in the electricity, or else the coated part of the wire would have become the hottest part instead of being the coldest. The explanation of this is through the fact proved by my experiments that electricity has a powerful attraction for heat. The current of electricity while passing through the uncoated part of the wire had free access to the air, and in consequence the electricity within the wire attracted to itself the latent heat of the air, and thereby the wire became hot, whereas the part of the wire coated with the covering of 285 mils. remained cool, because the current of electricity while within that part of the wire was prevented from attracting to itself the heat of the surrounding air, because the covering was interposed. The practical conclusion to be drawn from this is that the covering for wires should be air-tight and non-conducting of heat, as well as being insulating.

This subject has an important bearing on the recent experiments so ably carried out by Prof. Hughes. A copper wire consists of three things—first, molecules of copper; second, latent heat; and third, latent electricity. These three things in the normal state of the wire are all balanced and in a state of rest to one another, but the moment an electrician forces a current of electricity into that wire the balanced state of the aforesaid three things is disturbed. When the forced current of electricity enters one end of the wire it attracts to itself a portion of the heat which had hitherto been at rest within the embrace of the normal electricity of the wire, and hence a new adjustment of the relative positions of the molecules of the copper, of the heat, and of the electricity takes place within the wire, beginning at the anode end and continuing to the cathode end of it. It is during this readjustment of the molecules of the aforesaid three things that the wire is in that which has been called the variable state of it; and after the readjusted or new balanced condition of the three things has taken place the wire is then in that which is called the stable state.—Yours, &c. JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, 3rd May, 1886.

ERRATUM.—Dr. Romain Vigouroux writes, in reference to his letter in our last issue, to point out that *e* was substituted for the *o* in the last syllable of his name; and that the Trouvé battery to which he refers is not formed of *fluid* but of *moistened* elements, *i.e.*, is constructed with blotting paper saturated with sulphate of copper solution.

OBITUARY.

THE LATE L. H. F. MELSENS.

LOUIS HENRI FRÉDÉRIC MELSENS, a true *savan*, as distinguished as he was unassuming, has passed away. Though eminent in all branches of physical science, he will chiefly be identified with the system of lightning conductor—of large sectional area terminating above in numerous points, and connected below with a considerable surface in contact with damp earth or water—which he applied to the Hotel de Ville and the Palais de Justice, Brussels. He was Professor *emeritus* of the Belgian Veterinary College, Permanent Examiner at the Ecole Militaire, Gas Verificator to the Brussels Municipality, Member of the Belgian Royal Academies of Science and of Medicine, and also of many other scientific societies in Belgium and other countries, Commander in the Order of Leopold, and Chevalier in the Legions of Honour of Gustavus Vasa and Francis Joseph. He was awarded a prize by the French Institute for his discovery of the therapeutical properties of iodide of potassium, one only of his many chemical discoveries. Melsens died in harness.

In his 72nd year M. Melsens was working hard at the almost hopeless attempt to collate his many papers and notes; and he bitterly lamented the want of time to keep pace with scientific discovery. "Chemistry has now twenty branches," he remarked sorrowfully to a Belgian contemporary, "and a whole life is necessary for becoming conversant with one." The early part of Melsens' career was a hard struggle, for he was bent on devoting himself to scientific pursuit. His whole existence was one of thorough and painstaking research, not for glory, but for the love of it and for the benefit of mankind. He received a sad blow a few years ago by the death of an only daughter, who was about to be married; and, though every effort was made by his devoted spouse to rouse him from his melancholy, there is little doubt but that his useful life has been shortened in consequence. At the Military College Melsens was the terror of candidates for examination, whom he turned inside out to discover whether they were worth anything or not. He was, however, not only respected but beloved by both pupils and professors, and indeed by all who had the honour of his acquaintance. Melsens was born at Louvain on the 11th July, 1814, and died at Brussels on the 20th April, 1886, after a short but painful illness. He was buried at the Evere Cemetery in presence of a large concourse representing the various bodies with which he had been connected.

Four funeral orations were pronounced over his grave by M. Wehenkel, director of the Veterinary College; M. Leserre, Commandant of the Ecole Militaire; M. Mailly, director of the scientific section of the Belgian Royal Academy; and M. Warlomont, president of the Belgian Royal Academy of Medicine.

LETTERS.

A letter awaits G. W.

GAS AND ELECTRICITY.

Now that there is a prospect of free play for electric lighting enterprise, by the removal of those legislative restrictions which have hampered it during the past three years, the gas interests appear to have taken fright, and are doing their best by disparagement and misrepresentation to damage its rival in the business market. At least this is the natural inference to be drawn from recent animadversions in a certain section of the press usually identified with what are called vested interests. So far as these efforts are directed to warn the owners of gas property against a recurrence of the absurd panic which overtook them four or five years ago we are in entire sympathy with their object. We have never encouraged the idea that electricity was going to supersede gas all at once, or to lessen its business in an appreciable degree for a long time to come. Nor are we disposed to do so now, even though the improvements in the several branches of electric light engineering in the meanwhile have been so numerous and important that a more sanguine view of the new industry and a less hopeful one of the old would seem to be justified. What we have all along asserted, and what we repeat now with more confidence than ever, is that the electric light has its own peculiar sphere of usefulness, and a very wide sphere, quite apart from its competition with the older illuminant; and, secondly, that if electricity were allowed to compete on equal terms it would in many departments of life provide an agreeable light where gas is unacceptable, and in some others would thrust gas out of the field altogether.

To be candid, we think that in respect to the last-named field of operations electricity has a far better chance of success than its enemies seem to suppose, and that it will not be very long delayed. But for all that we do not in the least share their apprehensions as to the fatal consequences to gas property. Certainly there have been no grounds for such apprehension so far; and this not because electric lighting has made no progress, but because the demand for a better light created by the conspicuous superiority of electricity has given rise to a greater consumption of light all round, for which gas has furnished a very considerable quota. This effect will operate so long as the two systems are in a state of healthy competition; and will further tell for the benefit of gas manufacturers in the demand for gas engines, which are peculiarly adapted for some kinds of electric lighting installations. The high prices which gas property still maintains in the market, and the undiminished dividends it continues to pay show that there has been no falling off in the consumption of gas, or any slackening in the normal increase of consumption which has gone on hitherto year after year. There are, in fact, good grounds for suspecting that the GAS COMPANIES have profited largely by the advent of electric lighting. Certainly this is the case in the metropolis, and we have heard of no instance in the provinces where the effect upon gas property has been otherwise than beneficial.

The advantage to the public has been of course very great. Never have our main thoroughfares been so well lighted as they are at present, nor has there ever been such attention paid to considerations of public safety as has been the case under the stimulus afforded by the rivalry of the electric light. New gas burners have been invented which, whatever other merits they possess, have one that must commend them to the companies—the consumption of gas is on a scale proportionate to the magnificence of their illuminating power. We have not yet met with any invention that economises gas, though we hear of a great many. The universal tendency is towards profuse illumination, at all events out of doors, and undoubtedly gas interests have not suffered on that account; indeed, it has been spitefully observed in many quarters that the main consequence of a partial introduction of electric light has been to swell the bills for gas light. It is one consequence, no doubt; but another and more far-reaching effect is the one to which we have already adverted, namely, the creation of a standard of street lighting which the public will insist upon being maintained. And to some extent this remark applies to indoor lighting as well—at all events in large places of public assemblage. The electric light is firmly establishing itself in this direction, not perhaps rapidly, in superseding gas where gas has always been used, but in new buildings, and even in old ones where the change can be effected without serious loss. And in respect to indoor lighting, the demand is not only for a better but for a more wholesome and agreeable light. We may confidently predict, therefore, that the light of the future will be better, far better, than it has been under the undisturbed supremacy of gas; and that it will have to be purer and healthier than gas is ever likely to be.

Here the question arises, what are the probable consequences to gas and electricity which this state of things seems to foreshadow? So far as gas is concerned, we may leave it to take care of itself. Whenever the income of the gas companies is seriously imperilled they will not be slow to incorporate the new illuminant in their general system rather than see the business of supplying light pass gradually into other hands.

Digitized by Google

So far as we are concerned, the electric light will be as welcome whether supplied by a gas company or by a company exclusively devoted to electricity. But, occupying this impartial position, we feel ourselves entitled to warn the gas companies against their ignorant friends in the press, who talk as if the electric light had been tried and had failed in every particular. A city contemporary has just been treating the subject of "Gas and its Opponents" as if the electric light were slain already, and paraffin oil only living on sufferance. The production of electricity, says the *Citizen*, is as costly now as it was ten years ago, and is as uncertain and as troublesome; no improvements have been devised for its production or distribution, and its prospects are as gloomy as ever. Now, this kind of talk is unsafe as well as untrue. We are not "opponents" of gas; nobody that we know of is an opponent of gas; we are friendly to electric lighting, as every sane man is, when and where it can be had with proved advantage over gas, for its superior light and its infinitely preferable salubrity.

We prefer to enjoy our evening, for example, at such theatres as the Savoy or the Prince's, and to dine in comfort at such restaurants as the Holborn, not because we dislike gas, as an illuminant, but because we do not like it for dinner, or in the place of fresh air. And as regards open places and street lighting, we are content with the light that really does what it professes to do, and is at the same time not over costly. Our contemporary says as to this that the electric light is too expensive. Three years ago the same would have been said of those almost too gorgeous street gas lamps which electricity has frightened into being in such great abundance. We should like to know what they cost to erect, and what to maintain. They are expensive undoubtedly, but the public will have them or something as good or better; and what we say in this relation is, if it be the case, as we suspect it is, that electricity would be the cheaper illuminant, gas will sooner or later have to give way for it, even in the streets.

BLOCK SYSTEMS IN EUROPE AND AMERICA.

In Europe, according to a review in the *Bulletin* de la Societé Belge des Electriciens, the systems are not nearly so automatic as in America, owing to the lower price of labour, together with the fact that a thoroughly trustworthy pedal has not yet been invented. In the European systems the pedal does little more than call the attention of the signalman to the passing of the trains. In America they have not waited to find a perfect pedal before adopting automatic systems of blocking.

In the Roussean system each post carries a signal connected with two electric contacts (Fig. 1). In making the first contact

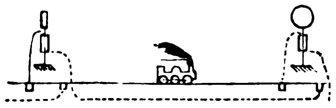

FIG. 1.

by passing over it, the train puts down the signal of the post and thus blocks itself. In making the second contact, it restores the signal of the preceding post, and thus unblocks the preceding section. The contact is produced by a piston placed in a vertical india rubber cylinder under the rail.

In the system of the Union Electric Signal Company each rail of a section forms a conductor insulated from the corresponding rail of the next section. At one extremity of the section there is an electric battery whose poles are connected one with each rail. At the other extremity of the section is the post bearing the signal, which is held up by magnetic attraction as long as the circuit is closed (Fig. 2). An interruption or great diminution of the current puts the signal down. When a train passes along the section, it closes the battery circuit by a small resistance, so that little of the current goes through the magnet, and the signal goes down.

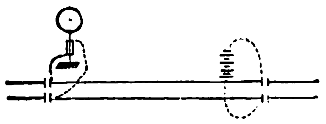

FIG. 2.

Hadden's system is used on the Pennsylvania Railroad and on the Chicago, Burlington, and Quincy Railroad. The electric system is connected by wires. There are two sets of signals, one on each side of the railway. Fig. 3 shows one set of two, one at each extremity of the section. When the armatures of the magnets are attracted, the signals are up; when a train enters a section and closes B′, the circuit is already closed by such a resistance that the current is not sufficiently affected to bring down the signal, the resistance of the secondary circuit thus made being the same as that of the principal one. When the train passes A it momentarily

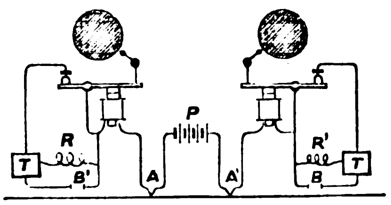

FIG. 3.

breaks the circuit, the magnets let go their armatures, and the signals fall. This action introduces a resistance in the circuit, which renders the current so feeble that it cannot again raise the armatures, and the signals remain down when the circuit is again made. Thus the signals are down at both ends of the section in which the train is. When the train passes A no effect is produced, but on passing B the current is restored, the signals go up, and remain so, since the rise of the signals removes the resistance.

NUMBER OF POLES AT THE SURFACE OF A MAGNETIC BODY.

In a note by M. Stielties, presented to the Academie des Sciences by M. Hermite at the meeting of April 5th, 1886, the author says:—The remark due to Gauss, that the existence of two north poles on the earth's surface necessitated that of a neuter pole, has been generalised by M. Betti (Teorica della forza Newtoniane). In considering a magnetic body bounded by a closed surface simply connected, he demonstrates that the whole number of poles is even.

The most simple method of treating this question has been given by M. Reech in an article inserted in the *Cahier XXXVII. du Journal de l'Ecole Polytechnique*. The author considers specially the maxima and minima of the function $\sqrt{x^2+y^2+z^2}$ at the surface of a body, but the reasoning is general, and, in applying it to the case of a magnetic body, the result of M. Reech consists in that the total number of neuter poles is surpassed by *two* units by the whole number of the other poles. This result includes the proposition of M. Betti.

By slightly modifying the reasoning of M. Reech, one can also treat by this method the case where the closed surface which limits the body is connected $2k+1$ times. One then finds that in general the number of neuter poles diminished by the number of other poles is equal to $2k-2$. As there is always at least one south and one north pole, it follows that the number of neuter poles is at least equal to $2k$.

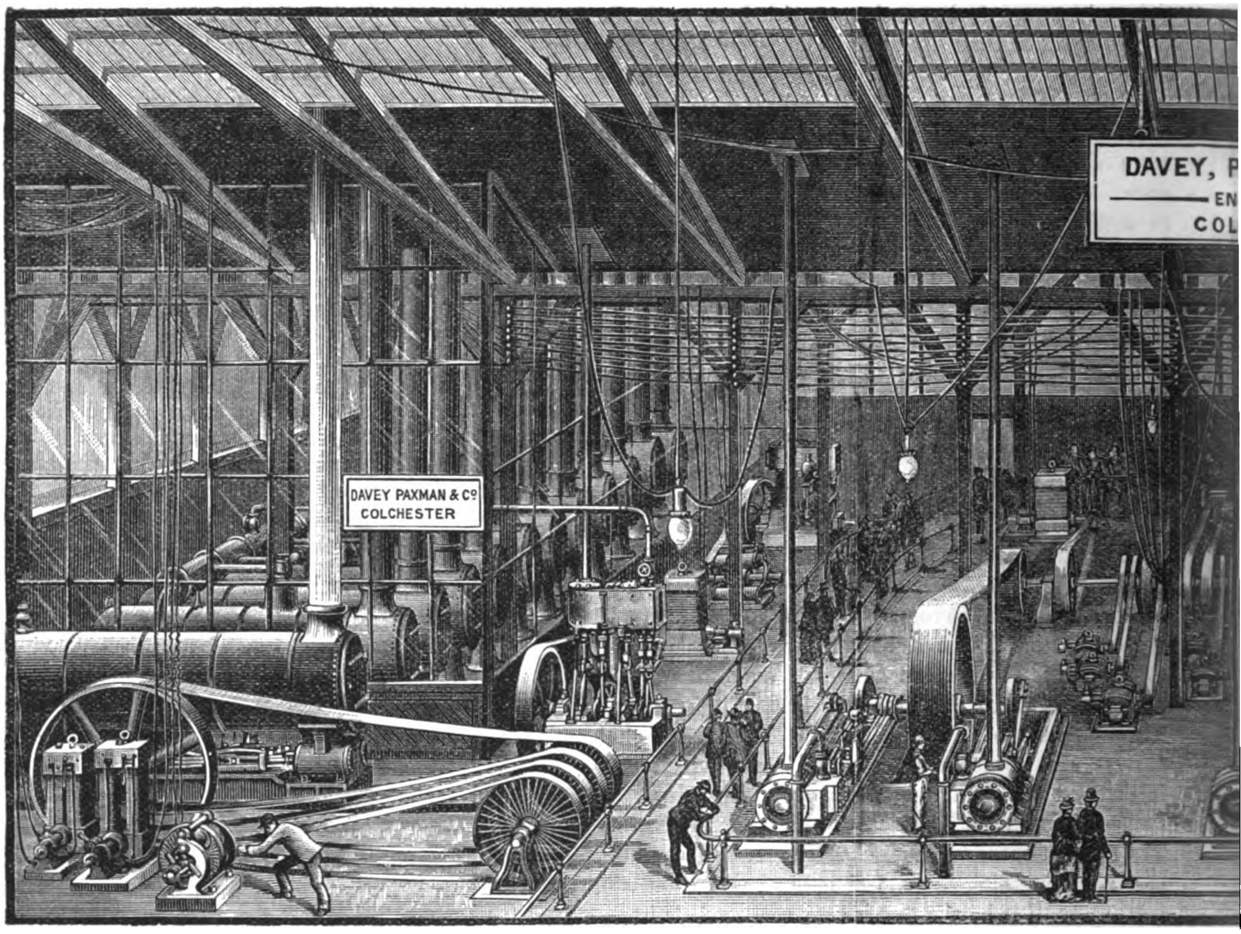
ELECTRIC LIGHT MACHINERY SHED AT THE

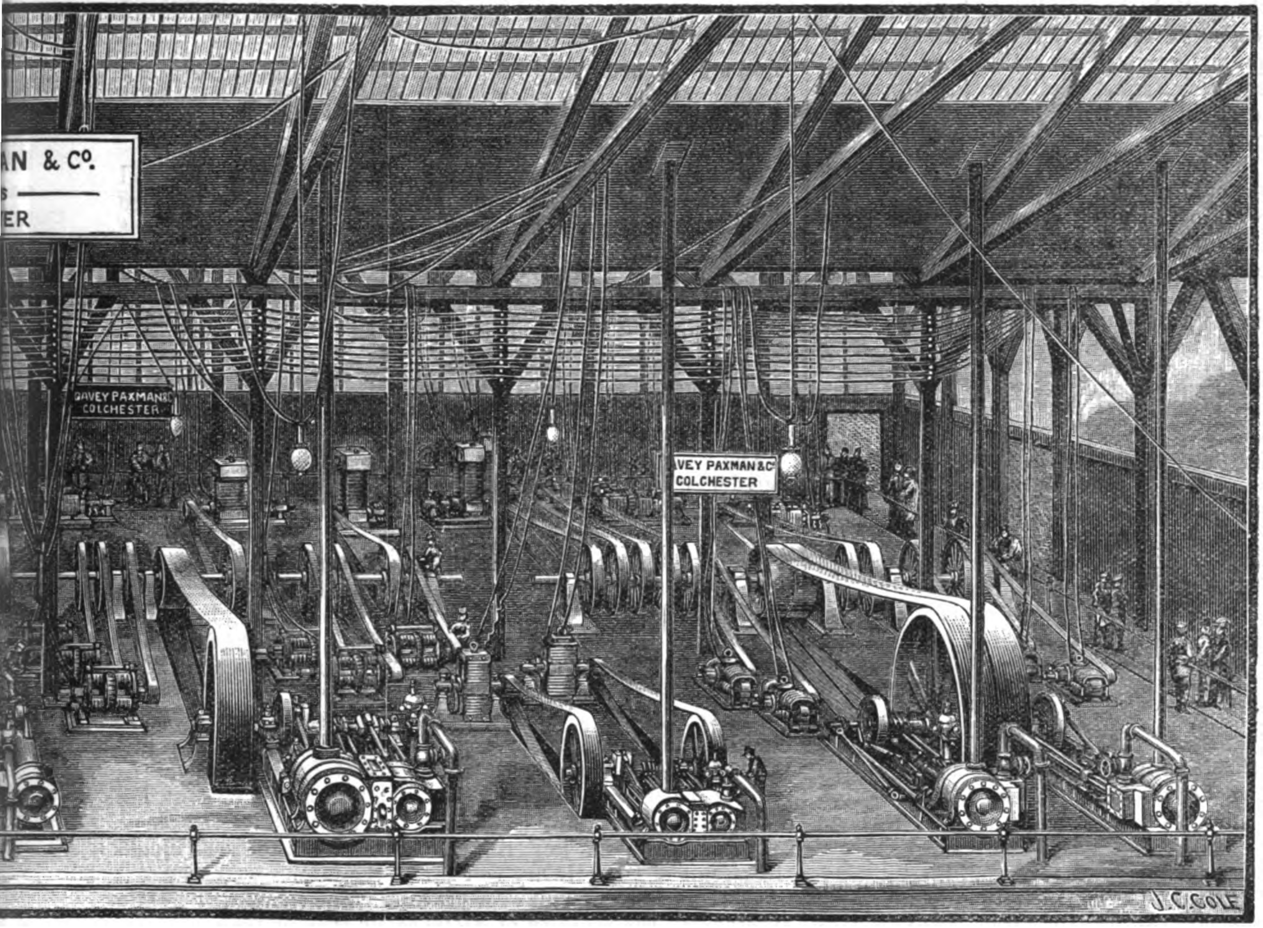


On Tuesday last, as most of our readers are aware, the Queen officially opened this year's Exhibition. We are not so much interested with the exhibits generally as with the lighting. Last year we were able to give an illustration of the arrangement of boilers, engines, and dynamos in the machinery shed—to be found in our issue of May 9th, 1885. We give a similar illustration now, and by comparison it will be seen that considerable alterations have been effected, making, in our estimation, this department far more presentable than at any other previous Exhibition. The firm of Messrs. Davey, Paxman and Co., of Colchester, who have supplied the engine and boiler power necessary for working the whole of the vast system of electric lighting throughout the late Inventions, Health, and Fisheries Exhibitions have again been retained for a similar service at the present Exhibition. Their machinery is completed, and amounts to 1,200 horse-power, and is supplied as follows:—No. 1 engine is a compound semi-fixed engine placed beneath the boiler, and capable of developing 120 horse-power; the two largest engines, Nos. 2 and 6, are of the coupled horizontal high pressure type, and capable of developing 700 horse-power if required. Fixed between these are three compound engines, Nos. 3, 4, and 5, No. 3 being on the coupled compound girder system, whilst Nos. 4 and 5 are of the horizontal compound receiver type; Nos. 7 and 8 are new vertical compound quick-speed engines, which can be employed for driving dynamos either direct or otherwise; No. 9 is a small quick-speed vertical engine, driving the dynamo on an entirely new system. All the above engines are provided with Paxman's patent automatic cut-off gear worked direct from the governors so as to ensure very steady and even running. The advantage of this system is that only just sufficient steam required for the duty is admitted to the cylinder at each stroke of the piston. This is one of the very few automatic arrangements which work with regularity and certainty. The cylinders are steam jacketed. It may be mentioned that at the Health Exhibition, 1884, one of the large driving bands on one of the engines suddenly broke, when the engine was transmitting about 350 horse-power; but the excellence of the automatic gear, even in this extreme case, prevented the engine from over-running. Steam is supplied to the semi-fixed engine by its own boiler, while that for the remaining engines is generated in eleven steel boilers of the locomotive type, each containing 610 square feet of heating surface, and working at 120lb. steam pressure. The fire boxes are of Davey, Paxman and Co.'s improved mild steel, which has given such excellent results. Above the boilers is placed a wrought-iron receiver so as to ensure perfectly dry steam. In addition to the above, Messrs. Davey, Paxman and Co. have an eight horse-power horizontal engine driving stamps for extracting gold from ore in a building erected by the Queensland Commission on the south promenade, also a four horse-power "Standard" vertical engine driving one of Paxman's patent safety machines for extracting from the soil diamonds and other precious stones. This machinery is in the South African Court. The steam for these two engines is supplied from Davey, Paxman and Co.'s range of boilers in the electric light shed.

From the notes given in the official guide book we get the following information about the lighting:—"The 'Old London' Street remains substantially as in previous years, the shops on the ground floor being utilised as offices for the various Colonial Commissioners, and the upper apartments reserved as reading and writing rooms, &c. The Central Railway Offices of the Royal Commission are contained in the houses opposite the Church Tower. The Colonial and Indian Exchange Rooms occupy the space forming the entrance to the narrow lane. The street is lighted at night by electricity, and novel and interesting effects, to give the appearance of moonlight, are introduced. On entering the buildings in the evening, visitors will miss the myriads of little star-like lamps which

Digitized by Google

COLONIAL AND INDIAN EXHIBITION.



formerly met the gaze in the southern galleries, and will find in their place fewer but more powerful arc lamps. The whole of the electric lighting is under the control of a committee composed of Sir Frederick Abel, chairman; Sir Francis Bolton, who directs the garden illuminations; and Mr. W. H. Preece, F.R.S., who specially looks after the lighting of the buildings. The motive power required for the internal lighting is supplied under contract by Messrs. Davey, Paxman and Co., of Colchester; the power absorbed amounts to 1,200 indicated horse-power. The principal galleries and courts are lighted by arc lamps, of which 160 are supplied by the Anglo-American Brush Electric Light Corporation (Limited); 140 by Messrs. R. E. Crompton and Co.; and 100 by the Pilsen-Jöel Electric Light Company (Limited)—making 400 lamps in all, each lamp giving a light equal to at least 1,000 standard candles. The Indian Palace, the dining rooms, and the different offices in the 'Old London' Street, as well as the Colonial and Indian tea houses, are lighted by means of incandescent lamps, supplied with current by the Edison-Hopkinson dynamo machines. These machines are lent by the Edison-Swan United Electric Light Company (Limited). The club dining rooms, over the West Arcade; the Chinese Pavilion, the Royal Box, underneath the clock tower; the executive offices, and the subway to the South Kensington Station, are lighted by incandescent lamps, which are fed by secondary batteries, lent by the Electrical Power Storage Company (Limited). These secondary batteries are charged by Edison-Hopkinson dynamo machines. The electric illumination of the gardens will be effected by means of about 20,000 small glow lamps (mostly of 10 candle-power each); and, in addition, a number of arc lamps suspended from tall masts will be used to give a strong moon-like effect when the illuminated fountains are not playing. This installation, as well as the whole of the work connected with the fountains, which have been enlarged and altered, has been carried out by Messrs. Galloway and Sons, of Knott Mill Iron Works, Manchester."

THE FORTHCOMING MARRIAGE OF THE CROWN PRINCE OF PORTUGAL.

A novel apparatus has recently been constructed by Messrs. Merryweather and Sons for exhibition at Lisbon, on the occasion of the wedding of the Crown Prince of Portugal this month.

It consists of a complete set of portable fountains, the water being supplied by two steam fire engines, and the jets will be illuminated at night by powerful electric lights placed underneath, the effect being similar to that which delighted so many thousands at the Inventions Exhibition last year.

The lighting part of the arrangement is undertaken by Messrs. Siemens Brothers and Co., who supply powerful dynamos and engines for the purpose, similar to those at the Indian and Colonial Exhibition.

The pipes forming the fountains are self-contained in the frame. Five large jets are thrown, either in plain streams or by means of an ingenious arrangement. These may be instantly changed into inverted cones of spray. Around the centre jet are arranged four nozzles, throwing fine spray.

The engines are Merryweather and Sons' well-known direct-acting type, as used in the London and other fire brigades, and are connected to the fountains by means of flexible leather hose.

The fountains will be fixed in a barge moored in the Tagus, the engines being placed in another boat, and the display will be carried out by engineers expressly sent out from this country by the makers of the apparatus.

THE EDISON "PHONOPLEX" OR "WAY-DUPLEX."

While the duplexing of through telegraph lines is now an easy matter and largely applied, the problem of increasing the capacity of lines employed in way service, such as upon railroads, has up to the present received no satisfactory solution. The ordinary duplex requires a fixed condition of the line, and when that varies even slightly it must be compensated for. Evidently, with twenty or thirty stations on a railroad line, or ordinary way offices, the communication with each office on the usual duplex plan would require a separate balancing for each one, and as one office is called up after another there would be a constant changing and loss of time. Besides, the ordinary duplex would not permit of two independent offices communicating with one or two other offices, and hence its value would be greatly restricted; indeed, its successful application would be well nigh impossible.

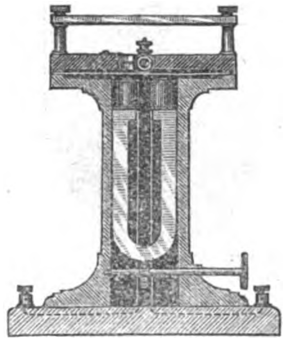

Fig. 1.—The Edison "Phonoplex"—The "Phone."

With these drawbacks in mind, Mr. Edison has devised a most ingenious method of doubling the capacity of telegraph lines, whether employed on way business or through traffic.

The name which he has given to the system, the "Phonoplex," or "Way-duplex," suggests immediately an application of the telephone, and such is indeed the case.

circuit a telegraph relay and a telephone, we may, by manipulating a key, operate the relay (and sounder) without producing a sound in the telephone, as the makes and breaks at the key are too gradual. But if through the same circuit we send the rapid discharge current from the secondary of an induction coil, or the extra current from a primary, it will cause a loud click in the telephone, but the current is too weak to affect the telegraph relay. Hence, by sending two kinds of currents over the wire, we obtain two effects which can be readily utilised for the purpose above described.

There are, of course, several points which must be observed in practice, and these have been well worked out, as will be seen in the diagram Fig. 2, which represents the equipment and arrangement of circuits in each office. The whole may for convenience be divided into the Morse and the "Phone" branch, although in reality there is no branch, as in the ordinary duplex, the line being continuous through both.

The Morse circuit at the left consists of the ordinary relay R, sounder S, and key K. In addition, however, there is a condenser C, placed as a shunt around the relay and key, the function of which will appear presently.

The "phone" circuit shown at the right contains the phone-sounder, with permanent magnet M, diaphragm D, and will be described more in detail below. The phone local battery P L B is in circuit with the primary coil I, which is always included in the line circuit, and also has a condenser C′ connected to its terminals. The circuit coming from one terminal of the coil I is split, one branch going directly to the back stop of the relay R′, and the other to the front stop, but including a variable resistance R″. The phone operator manipulates the key K′ as usual.

For the sake of clearness, we will suppose that the Morse circuit is not at work. The circuit would then be from line through the phone, thence through coil I, through key K, relay R, battery and earth. But in addition the current has a by-pass through the condenser C. Now, when the phone operator closes his key K′, the lever of the relay R′ breaks the circuit of the primary coil I, and the intense extra current of short duration is sent over the line. The effect of the extra current and the rapidity of discharge is still further increased

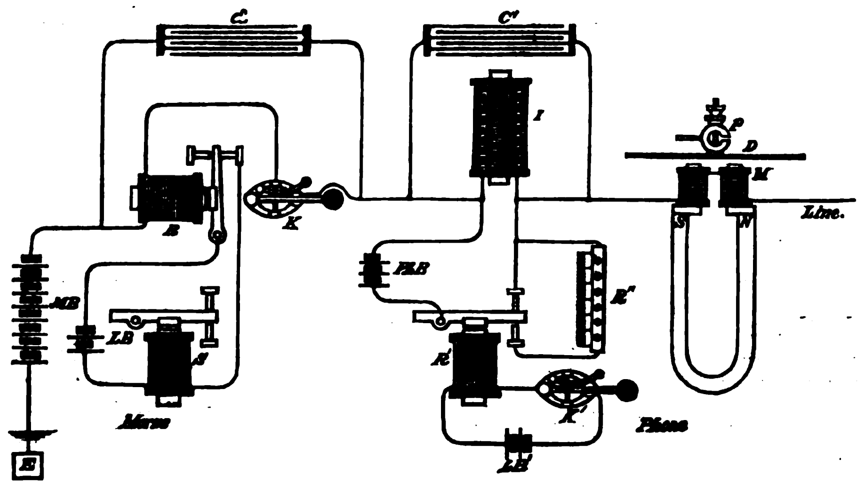

Fig. 2.—The Edison "Phonoplex"—Equipment and Arrangement of Circuits in each Office.

While Mr. Edison's method of working is analogous to that of Van Rysselberghe in his system of simultaneous telegraphy and telephony over the same wire, he, nevertheless, has an entirely different object in view, and that is, to convert the telephone on the circuit into a sounder, so that the regular Morse can be read from it.

Before entering into a description of the details, it may be well to give a short outline of the principle employed.

It is well known that if the emission and extinction of the current in the telephone be gradual, the diaphragm will be merely bent, and will return to its original form without emitting a sound. But if the make and break in the current be rapid, the telephone diaphragm will "snap," and so give forth audible sound. If now there are included in the same

by the condenser C′, which is placed there for that object. This intense and rapid extra current does not affect the relays on the line, but passing through the condenser C, acts powerfully on the diaphragms of the phones and gives a violent motion to the snapper P.

It will be noticed that every movement of the lever of the relay R′ sends two impulses over the line—one on breaking the circuit and another on making at the front stop. The extra current produced by the latter, however, is greatly diminished by the resistance R″, and follows so quickly upon the first that there is but one click heard in the phone. When the armature lever of the relay R′ is released by the raising of K′, the reverse operation takes place, for we then have first a weak extra current over the line followed by a stronger one. This change

Digitized by Google

in the order of the currents causes a difference in the sound emitted by the phone, just as in the ordinary sounder the sound of the front stroke differs from that of the back stroke. In this way the signals received in the phone can be clearly distinguished.

Thus far we have supposed that the Morse operator is not working. From what has gone before, however, it is evident that it makes no difference whether his key is closed or not, as the condenser C is all sufficient for the transmission of the high potential phone current.

In additional to the gradual emission of the Morse current which the operator's key produces, there is also added thereto the retarding influences of the relays in circuit and the primary coils I, which then have the same functions as when applied to the Van Rysselberghe system, in which they act as "graduators." While offering no resistance in speed to the Morse working, they "graduate" the emission of Morse currents so that they merely deflect the diaphragms of the "phones" without snapping them and producing a sound.

Though a variable resistance, R″, is used, it is merely for the purpose of varying the sound in the "phone" to suit the operator's ear, and once set is never disturbed.

The "phone" itself is a simple and ingenious apparatus, and is shown in section in Fig. 1. Resting upon a wooden base is a hollow column of brass, within which is placed a magnet with the bobbins facing the diaphragm. At the lower end of the magnet there is a rack and pinion, by which it can be adjusted with reference to the diaphragm. To the centre of the latter there is attached a screw-threaded pin, with thumb-nut and binder at the top. Encircling the pin loosely is a split-hardened steel ring which rests upon the diaphragm. When the latter is snapped by the attraction of the momentary current in the magnet, it throws the ring violently against the stop-nuts, and produces a sharp click, far louder than that from the ordinary sounder. The steel ring has a pin projecting from its side that passes between two prongs, which, while permitting free up and down motion, prevent the ring from turning and altering the sound. Over the top of the "phone" there is clamped a thin brass plate as a protection for the projecting screw.

This phonoplex system is especially valuable for railway telegraphy, but is equally well adapted for regular lines, and is already in operation in various places. Several city lines in this city are equipped with it, and the Baltimore and Ohio Telegraph Company and Railroad have it in operation between Baltimore, Harrisburg, and Pittsburgh.

The "phone" local battery only requires three or four cells for the longest distances, say two or three hundred miles. As stated before, the operation of the system is extremely simple, and the condition and length of the line has no effect upon the working. We believe that the system is destined to a rapid spread. Its simplicity is one of the strongest points in its favour.—*Electrical World.*

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 500.)

If we regard the whole electric field as a dynamical system, and to fix our ideas consider an element a of the dielectric, and the current, which is supposed to vary, then, since a variation in the current polarises a, *i.e.*, produces a change in its structure, there must be mechanism connecting the current with the element a; but if this is so then it follows from dynamical principles that a non-uniform variation in the structure of a must produce a change in the current—in other words, that a change in the rate of change of the polarisation of a produces an electromotive force on the current, *i.e.*, that the change of polarisation produces an effect analogous to that of an ordinary conduction current. We may illustrate this by a purely dynamical example. Suppose we have a dynamical system defined by two co-ordinates p and q, and let T be the kinetic energy of the system and V the potential energy; then by Lagrange's equation the force tending to increase q

$$= -\frac{dV}{dq} + \frac{dT}{dq} - \frac{d}{dt}\frac{dT}{d\dot{q}}.$$

Now, if there is a force tending to alter q which depends upon the acceleration of p, there must be a term in the kinetic energy of the form

$$A\ddot{p}q;$$

but if we apply Lagrange's equations to the p co-ordinates we see that this term implies the existence of a force tending to increase p equal to

$$-\frac{d}{dt}A\dot{q},$$

so that an acceleration of q will produce a force tending to alter p. To make this applicable to the case of the current and the dielectric, we have only to suppose that $\dot{p}$ represents the current, q the polarisation of the dielectric. That a change in $\dot{p}$ produces a change in q is shown by the fact that the dielectric is polarised when the current is changing, and this shows that there must be a term of the form $A\dot{p}q$, in expression for the kinetic energy; from this it follows that a change in $\dot{q}$, *i.e.* in the rate of change of the polarisation, will produce an E.M.F. on the circuit. As the variation of the dielectric polarisation produces the same effect as a conduction current, we must in the case, when both conduction current and alteration in the polarisation are present, look upon the true or effective current as the sum of the conduction current and the change in the polarisation.

The components f, g, h of the dielectric polarisation are defined by the equation

$$f = \frac{K}{4\pi}X, \qquad g = \frac{K}{4\pi}Y, \qquad h = \frac{K}{4\pi}Z,$$

where K is the specific inductive capacity of the medium, X, Y, Z the components of the electromotive force. If u, v, w are the components of the effective current, p, q, r the components of the conduction current, then Maxwell in his paper on a "Dynamical Theory of the Electromagnetic Field," *Phil. Trans.*, 1885, puts

$$u = p + \frac{df}{dt}, \qquad v = q + \frac{dg}{dt}, \qquad w = r + \frac{dh}{dt}.$$

Since $$\frac{dp}{dx} + \frac{dq}{dy} + \frac{dr}{dz} = -\frac{d\rho}{dt}$$

and $$\frac{df}{dx} + \frac{dg}{dy} + \frac{dh}{dz} = \rho,$$

where ρ is the volume density of the free electricity, we see that

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = 0.$$

If the values of the quantities in a medium A be denoted by putting the suffix 1 to the symbols representing them, and those in another dielectric B by putting the suffix 2, then if l, m, n are the direction cosines of the normal from A to B, we have at the boundary of the two media

$$l(p_1 - p_2) + m(q_1 - q_2) + n(r_1 - r_2) = \frac{d\sigma}{dt}$$

$$l(f_1 - f_2) + m(g_1 - g_2) + n(h_1 - h_2) = -\sigma,$$

where σ is the surface density of the electricity; thus

$$l(u_1 - u_2) + m(v_1 - v_2) + n(w_1 - w_2) = 0;$$

so that u, v, w satisfy the same equations as the components of the velocity of an incompressible fluid.

This assumption about the magnitude of the effects produced by the alteration in the dielectric polarisation makes the mathematics of the theory as simple as possible. If Maxwell had merely assumed that the alteration of the dielectric polarisation produces effects analogous to those produced by ordinary conduction currents, and that the equivalent conduction current was proportional to the rate of alteration of the dielectric polarisation, then these equations would have been

$$u = p + a\frac{dX}{dt}, \quad v = q + a\frac{dY}{dt}, \quad w = r + a\frac{dZ}{dt};$$

Digitized by Google

so that in a homogeneous dielectric

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=-\frac{d\rho}{dt}\left\{1-4\frac{a\pi}{k}\right\},$$

$$l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)=\frac{d\sigma}{dt}+a_1\frac{dN_1}{dt}-a_2\frac{dN_2}{dt}$$

where N is the component of the electromotive force normal to the surface.

Maxwell's assumption is that $a=K/4\pi$, and this makes the equations much simpler; it is, however, important to remember that Maxwell's theory of the dielectric involves the two assumptions—

1st. That alterations in the dielectric polarisation produce effects analagous to those of ordinary conduction currents;

2nd. That the magnitude of the equivalent conducting current $=d\left\{\frac{K}{4\pi}F\right\}/dt$, where F is the electromotive force at the point; this is equivalent to saying that all the currents are closed currents, and that there is no discontinuity in them.

Maxwell develops his theory by means of the principle of the Conservation of Energy.

Let us consider an electric field full of currents, whether ordinary conduction currents or polarisation ones. Then this field may be looked upon as a material system, and all the phenomena have to be explained as the effects of the motion of this system; a current must be looked upon as a change in the structure of the system, and so capable of representation by means of the differential coefficients of the co-ordinates fixing the system; we can thus represent the current at each point as the differential coefficient of some generalised co ordinate fixing the system; the components u, v, w of the current passing through an element dx, dy, dz may be looked upon as the rates of change of some generalised co-ordinates; we may write the energy as

$$\tfrac{1}{2}\iiint\{Fu+Gv+Hw\}\,dx\,dy\,dz,$$

where F, G, H may be looked upon as momenta corresponding to u, v, w. It remains to identify F, G, H with known quantities. Maxwell does this by the aid of Faraday's result, that the electromotive force round a circuit equals the rate of diminution of the number of lines of force passing through it.

Let us consider a single linear circuit in which the current is i, or say dq/dt, then the energy

$$=\tfrac{1}{2}\int\frac{dq}{dt}\left\{F\frac{dx}{ds}+G\frac{dy}{ds}+H\frac{dz}{ds}\right\}ds,$$

where ds is an element of circuit; but by Lagrange's equation the force tending to increase q, *i.e.* the electromotive force in the circuit,

$$=-\frac{d}{dt}\int\left(F\frac{dx}{ds}+G\frac{dy}{ds}+H\frac{dz}{ds}\right)ds\,;$$

so that

$$\int\left(F\frac{dx}{ds}+G\frac{dy}{ds}+H\frac{dz}{ds}\right)ds$$

equals the number of lines of force passing through the circuit; but if dS be an element of surface closing up the circuit, l, m, n the direction cosines of the normal, then by Stokes' theorem

$$\int\left(F\frac{dx}{ds}+G\frac{dy}{ds}+H\frac{dz}{ds}\right)ds$$

$$\iint\left\{l\left(\frac{dH}{dy}-\frac{dG}{dz}\right)+m\left(\frac{dF}{dz}-\frac{dH}{dx}\right)+n\left(\frac{dG}{dx}-\frac{dF}{dy}\right)\right\}dS\,;$$

but the number of lines of force passing through the circuit

$$=\iint(la+mb+nc)dS,$$

where a, b, c are the components of magnetic induction, so that

$$a=\frac{dH}{dy}-\frac{dG}{dz},\qquad b=\frac{dF}{dz}-\frac{dH}{dx},\qquad c=\frac{dG}{dx}-\frac{dF}{dy}.$$

To connect a, b, c with the current, Maxwell makes use of the principle that the line integral of the magnetic force taken round any closed curve equals the current flowing through the curve. This leads to the equations—

$$4\pi u=\frac{d\gamma}{dy}-\frac{d\beta}{dz},\qquad 4\pi v=\frac{d\alpha}{dz}-\frac{d\gamma}{dx},\qquad 4\pi w=\frac{d\beta}{dx}-\frac{d\alpha}{dy}.$$

so that if μ be the coefficient of magnetic permeability,

$$4\pi\mu u=\frac{dc}{dy}-\frac{db}{dz},$$

and so on. Substituting the vales of a, b, c, given above, we find

$$4\pi\mu u=\frac{d}{dx}\left\{\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}\right\}-\nabla^2F,$$

with similar equations for G and H.

Now, Von Helmholtz, in his paper "Ueber die Bewegungsgleichungen der Elektricität für ruhende leitende Körper" (*Crelle*, LXXII. p. 57; *Gesammelte Werke*, II. p. 545), has investigated the most general expressions for F, G, H, consistent with the force between two closed circuits agreeing with that indicated by Ampère's theory, and he finds that if the circuits are closed circuits, as Maxwell assumes all circuits to be, then

$$\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}=0,$$

and therefore

$$4\pi\mu u=-\nabla^2F,$$

with similar equations for G and H. These equations are sufficient to determine the quantities F, G, H.

Maxwell does not at once put $dF/dx+dG/dy+dH/dz=0$; he writes J for this quantity, and puts

$$\chi=\iiint\frac{J}{r}dx\,dy\,dz.$$

Then

$$F=\iiint\frac{\mu u}{r}dx\,dy\,dz+\frac{d\chi}{dx};$$

as, however, he subsequently puts $J=0$, we may at once simplify the equation by making this assumption.

Since the kinetic energy equals

$$\tfrac{1}{2}\iiint(Fu+Gv+Hw)dx\,dy\,dz,$$

we see by Lagrange's equations that the electromotive force tending to increase u

$$=-\frac{dF}{dt};$$

in addition to this there is the force arising from the electrostatic potential ϕ, so that the total electromotive force parallel to the axis of x

$$=-\frac{dF}{dt}-\frac{d\phi}{dx},$$

so that if σ be the specific resistance of the substance, K its specific inductive capacity, then

$$\sigma p=\frac{4\pi}{K}f=-\frac{dF}{dt}-\frac{d\phi}{dx};$$

but

$$u=p+\frac{df}{dt}=-\frac{1}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}-\frac{K}{4\pi}\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\};$$

but we saw before that

$$4\pi\mu u=-\nabla^2F.$$

(To be continued.)

DELANY'S SYSTEM OF SYNCHRONOUS MULTIPLEX TELEGRAPHY.

The following description, admirable for its clearness and brevity, has recently been issued by the English Postal Telegraph Department for the guidance of its officers in fixing and working the Delany Telegraph:—

1. Delany's system is based upon two main principles, first, that of synchronism, or the simultaneous motion of similar pieces of apparatus at two different places; and secondly, that of distributing to several telegraphists the use of a wire for very short equal periods of time, so that practically each telegraphist has the line to himself during these periods. The combination of these principles of working was introduced by Meyer in 1873; it was improved upon by Baudot in 1881; synchronism was perfected by Delany in 1882, and the system completed in 1884.

2. As Delany's system differs very markedly from what are known as the duplex and quadruplex systems, it is proposed for clearer

Digitized by Google

definition to give to the modes of working his system names based on the Greek word *hodos*, a way. Thus a two way mode of working, or a mode by which two messages are practically sent at the same time, will be *diode* working, three way *triode*, four way *tetrode*, five way *penthode*, and six way *hexode*. Duplex and quadruplex are such well rooted and explicit terms, defining particular modes of working by compensation, that their application to different modes of working based on a different idea may lead to confusion, while new and distinct terms will confine the attention to the new and distinct system.

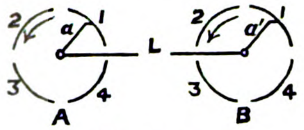

Fig. 1.

3. A and B are two separate offices connected together by a line wire, L. If the arms *a* and *a'*, in electrical connection with line wire L at A and B, rotate simultaneously around the circles 1, 2, 3, 4, in the direction of the arrows, making contact upon the segments as they pass, then when *a* is at A 1 *a'* will be at B 1, when *a* is at A 2 *a'* will be at B 2, and similarly for 3 and 4. If 1, 2, and 3, and 4 at each office be each in connection with a set of similar telegraphic apparatus the four sets at one office will be in direct communication with the four sets at the other office as the arms *a a'* touch their corresponding segments. Thus for each rotation of the arms the instruments at A 1 and B 1 will be in direct communication with each other *once*; and so on with those at A 2 and B 2, &c.

4. If each segment be divided into four segments, and by means of these be connected with the four instruments, instead

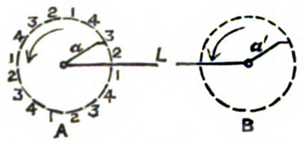

Fig. 2.

of with only one of them, then during one complete rotation each arm will place corresponding instruments in communication with each other *four* times; or, if each circle be divided into 40 segments and each of these 40 into four segments, then corresponding instruments will be in communication with each other *forty* times during each complete rotation of the arms "*a*" and "*a'*." In Delany's apparatus there are 84 segments in the whole circle, and these are grouped differently according to the number of ways of working. Hexode working requires one grouping, triode another, diode another, and so on.

5. Two tuning forks pitched to absolutely the same note, and set in vibration by currents like an electric trembling bell move in synchronism, but the synchronism cannot be maintained. The deposition of dirt, dust, or moisture, changes of temperature, variation of current, produces changes which affect the rate of motion. Paul la Cour, of Copenhagen, invented an ingenious way to

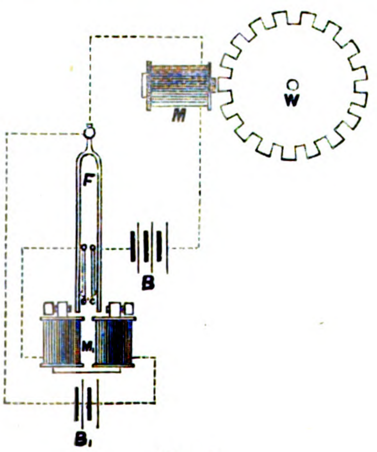

Fig. 3.

maintain the synchronism. F is a tuning fork vibrating between the poles of magnet M_1. There are two contact points *c c'*. At *c* is completed a circuit containing the battery B, and an electro-magnet M. The other contact *c'* completes the circuit containing the battery B_1 and the electro-magnet M_1. Every time the tuning fork touches the contact point "*c*" a current is sent through the electro-magnet M, which, therefore, is magnetised once for every excursion to and fro of the fork. In front of the magnet M there is a wheel, W, whose teeth are of iron, and every time the magnet M is excited attraction is momentarily exerted on the nearest tooth. If the tooth is approaching the pole it is urged forward, if it is moving away from the pole it is retarded. Hence the wheel is propelled with wonderful uniformity, and with considerable force. The electro-magnet M_1 is similarly excited, and it maintains the fork in constant vibration. This "phonic wheel," as it is called, Delany uses in connection with a "distributor"; but he has adopted a reed instead of a tuning fork.

6. The "distributor," as arranged for hexode working, is shown by—

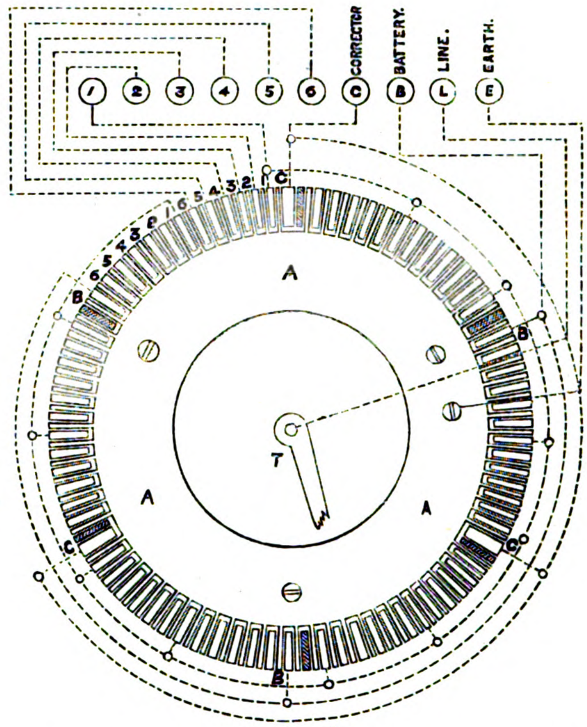

Fig. 4.

The circle is divided into six groups, each group having 12 platina faced brass segments insulated from each other, and being separated from the next group by what are called the two correcting segments, one (shaded) called "dead," and the other (clear and marked B or C) called "live." The segments are not only insulated from each other but are separated by the spokes of the brass rim A, which is connected with earth. Each group of 12 segments is further subdivided into two sub-groups of six, in which the corresponding segments are connected, so that 1 and 1, 2 and 2, 3 and 3, and so on are electrically joined together. Not only so, but they are connected to every corresponding number in the other groups around the circle. In Fig. 4 the segments in only two of the sub-groups are numbered, but the remaining 10 sub-groups must be understood to be all numbered in the same way. The twelve segments numbered 1, are electrically connected to the telegraphic instrument numbered 1; the twelve segments numbered 2 are connected to the instrument numbered 2, and so on. The first, third, and fifth "live" segments are connected together, as also are the second, fourth, and sixth, but the first three are intended to *receive* currents from the distant station, while the second three are connected to a battery B, and so can *send* currents to the distant station. The "dead" segments are so arranged that one is fixed *before* each receiving "live" segment, and one after each sending "live" segment. The correcting segments are connected in the manner described for lines whose inductive capacity is small, and where the retardative effect on the current is consequently slight; but when the capacity is considerable, the segments which are called "dead" are brought into use; the sending correcting battery is then connected to the "dead" segments immediately in front of the broad segments, and the receiving correcting relay is connected to the "dead" segments immediately following the segments shown in the figure as "live" B segments. This arrangement gives a space of one segment to allow for retardation of the current when the capacity of the line exceeds three microfarads. When, however, the capacity is within that amount this space is not required; indeed, it would be disadvantageous, because there is very slight loss of time in the transmission of the signal. The receiving correcting segment is therefore extended in such a manner as to meet the trailer, and so receive the correction almost as soon as it is sent. It is not really necessary that the segment should be made broad, but only that it should be moved in the direction indicated; it is only made broad to fill up the space.

Digitized by Google

The arm or trailer T passes lightly on the surface, and moves continuously round the circle, coming successively in contact with every segment. It moves in the opposite direction to that of the hands of a watch. It is electrically connected to the line wire L. In every rotation it makes 84 electrical contacts, 72 of which are for telegraphing, while the others are for maintaining synchronism. The function of the trailer is to place the line wire successively in connection with the segments in the different groups. The currents of electricity that flow through the line wire are dependent upon the operations performed upon the telegraphic apparatus, and they are broken up into short rapid pulsations or impulses by the momentary contacts made by the trailer. The uniform rotation of the trailer is produced by La Cour's wheel, shown in Fig. 3.

7. Fig. 5 shows the La Cour wheel in connection with Delany's actuating, correcting, and synchronising devices. The iron-toothed wheel A is placed before the poles of the electro-magnet D, which is magnetised periodically and regularly by currents from the battery B'_2 sent at each vibration of the reed E' at H'. It propels with great uniformity the toothed wheel, to the axle of which is attached the trailer T. The impulse must be given when the tooth is at c and cease when it is at c' (Fig. 6). Momentum takes it on until the next tooth comes to c, when the next impulse is given. The impulse must last while the tooth moves from c to c'. If it continued beyond that time it would check the motion of the tooth. As the impulses are due to the vibrations of the reed the motion of the wheel must follow exactly the vibrations of the reed. Resistances

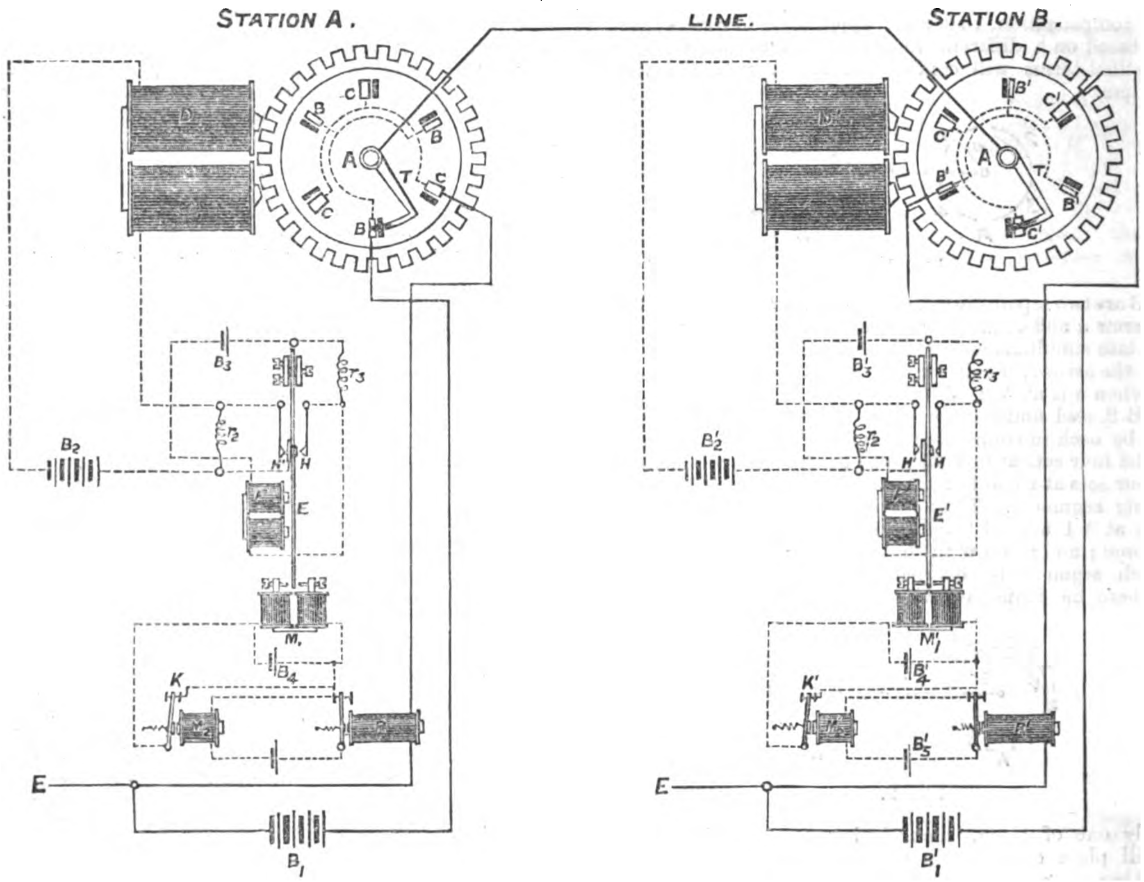

FIG. 5.

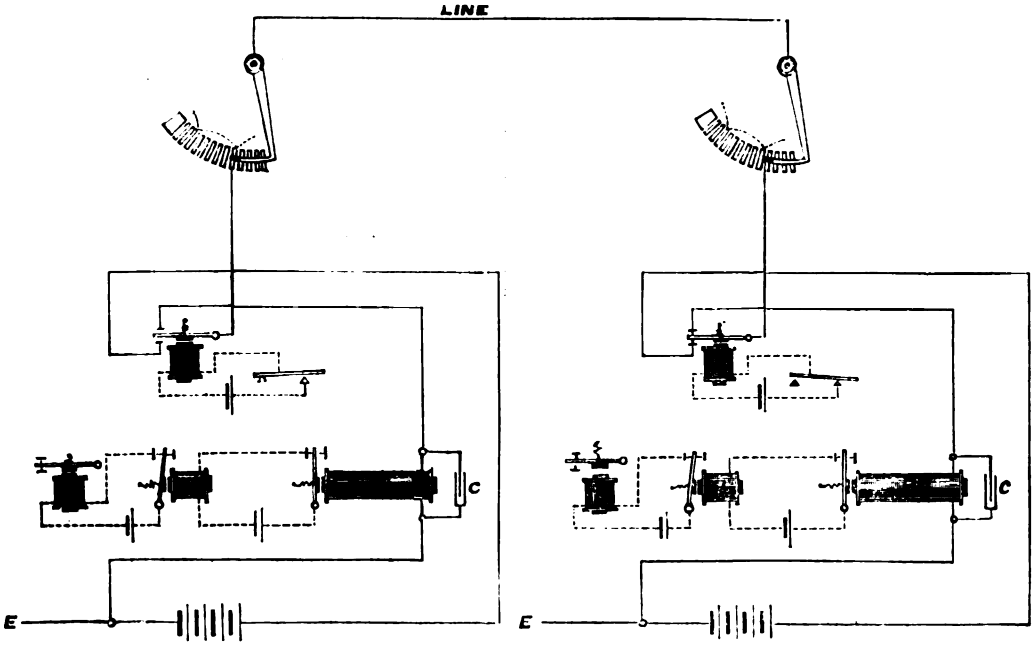

FIG. 7.

r_2 and r_3 (Fig. 5) are placed as shunts around each of the contacts H and H′ to prevent sparking. The vibrations of the reed are maintained by the electro-magnet F′ excited by the battery B'_3 every time contact is made at H. The end of the reed E′ vibrates between the extended pole pieces of the electro-magnet M'_1, and thus it vibrates in a magnetic field. This magnet is excited by the battery B'_4 whenever contact is broken at K′, and this contact at K′ is broken whenever the current from battery B'_5 ceases to flow in M'_2. This depends on the action of the relay R′, which is excited by currents received from the distant station coming through the "live" correcting segments of the "distributor" there, and which, therefore, when its armature is attracted breaks the local current flowing through M'_2. When the magnet M'_1 is excited, the magnetic field in which the iron reed vibrates tends to retard its rate of vibration by attraction, so that if it vibrates too frequently its rate is checked. The normal rate of vibration may be adjusted by a sliding weight, or in various other ways not shown in the figure. The mode in which each set of apparatus is connected up is shown by Fig. 7. A portion of one group of segments of the "distributor" at each station is indicated, and the trailers are shown to be in contact with corresponding segments which direct the current to the telegraphic apparatus. There is nothing peculiar in the telegraphic apparatus (the usual Morse sounder set), except the relay R, which by its form is rendered sluggish, so that the sharp, rapid currents collected by the trailer are practically made continuous in their action on the armature of the relay. The currents flowing through the line wire are short, sharp, rapid impulses or waves of electricity, and to convert these waves into telegraphic symbols, such as Morse characters, some mode is needed to render them continuous for the duration of a dot or a dash. The relay has a condenser C (Fig. 8), and permanent horseshoe magnet NS fixed below the coils. The cores are thus polarised.

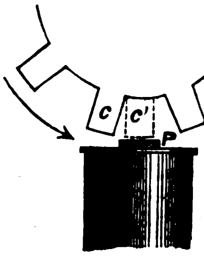

Fig. 6.

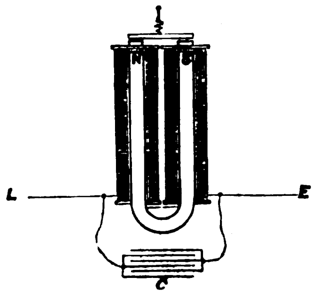

Fig. 8.

The result is that the self-induction of the coils, adjusted by the condenser, retards the demagnetisation of the core, so that the effect of the rapid succession of short currents is made continuous upon the armature of the relay, and the marks are made as though they were produced by continuous currents. Dots and dashes are thus recorded without breaks. The relay R (Fig. 7) actuates an uprighting relay, M, which in turn actuates the sounder S. This arrangement is introduced because the ordinary method of completing the local circuit is too slow and the contacts are not firm enough. It has been mentioned that each segment is separated by an earth contact—a spoke of the brass rim. This is done to favour the rapid discharge of the static charge to earth between each electrical impulse or current. The apparatus being ready, six pairs of corresponding telegraphists are placed in communication and each pair has virtually a circuit to itself.

It will be observed that in Fig. 5 only the correcting "live" and "dead" segments are shown. Of the "live" segments, those in connection with the battery are of the usual dimensions, while those in connection with the reed correcting apparatus are broad. This is to admit of corrections being made *before* the working segments are affected. Want of synchronism is thus prevented. When the trailer at station A is on the narrow segment, that at station B is on or near the broad segment. If the wheels are in perfect synchronism, the trailer at B is on the "dead" segment; when at A it is on the sending "live" one, and *vice versâ*; hence no current flows; but when the wheel at B is in the least degree in advance of that at A, then the trailer at B is on the receiving "live" segment, a current flows, it excites relay R′, the electro-magnet M'_2 is also excited, the magnetic field is formed, and the vibration of the reed E′ is retarded. Perfect synchronism is again obtained, and the correcting currents cease to flow. Six correcting currents can be sent at each revolution, three in one direction and three in the other. Thus a deviation of a thousanth of an inch can be speedily rectified.

This method of Mr. Delany's is perfectly automatic in its action, and it maintains synchronism to an extent that has never before been known. Attempts have been made to synchronise by sending correcting currents in one direction and applying the corrections mechanically to moving parts. Baudot brings to bear a friction break by such means, but it has not been successful in practice, whereas Delany's method is practical and successful. The "distributor" rotates nearly three times in one second, hence 252 contacts are made each second in hexode working. The distance to which the system can be worked hexode is limited, for owing to the retarding effect of static induction the number of currents which can be sent per second is limited by the static capacity of the line. Now, as the static capacity of the line has the effect of retarding the speed of the current, it follows that the limit of working is dependent on the magnitude of the static capacity, for if the current be late it will enter the wrong segments, and confusion of signals will result. The retarding effect of static capacity can be met by making each group of a greater number of segments, or by making the segments of greater breadth; but this has the effect of reducing the number of ways of working. Either plan would reduce the hexode to tetrode or triode working.

So far, it should be understood, the system has been described as one for working in either direction (not simultaneously as in duplex, but alternately), as in ordinary simplex working. If, however, it be regarded as a system for working in one direction, distance has not the same effect upon it. If static capacity only so reduces the speed of the current that while it leaves segments 1 at station A it enters segments 2 at station B then it is possible still to work five ways *in one direction*, for every other segment will be advanced one. For this mode of working two wires are necessary, one for sending and the other for receiving, but it has this advantage that two wires can be converted into ten circuits. Segment 6 is rendered useless in consequence of its currents arriving at B when the trailer is on the correcting segments. Working in either direction, hexode is feasible between London and Brighton, but tetrode is the limit to Bristol and Manchester. In one directon, however, to Bristol and Manchester, even six circuits have been operated, so that with two wires 12 circuits might be worked, six in each direction.

The great advantage of the system is that it does not disturb the general mode of working adopted in this country. The sounder system is retained. Key working is maintained All initial delay due to punching is avoided. The skill of able telegraphists is fully utilised. Each telegraphist has an independent circuit, so that he has not to wait for a lagging co-operator, as in quadruplex. When there is a rush of traffic in one direction the system can be worked all in one direction, and not only half of it as in the quadruplex. The system, moreover, is only in its infancy, and there is little doubt that further experience will lead to its being improved.

PROF. FORBES' CANTOR LECTURES.

(Continued from page 481.)

LECTURE II.

In the course of my last lecture I showed you the generation of electrification, and the electric forces which were thereby produced; I explained to you what we meant by saying that two things have a difference of electrical potential, and I also demonstrated to you the condition that exists when two bodies have a difference of electrical potential—that is to say, that there is then created an electromotive force, and if that electromotive force is capable of acting through a conductor, you saw that there is a momentary current and a rearrangement of the electrification. If, however, the electromotive force is acting upon an insulator, no current can pass. There is simply a state of strain created in the insulating medium, which is ready to produce the phenomena of induction as soon as the facility is offered to the apparatus. We are accustomed to measure that difference of potential in terms of some unit, and the unit that has generally been adopted is called a volt, and when I say that there is a difference of potential in the machine I am using, between the two knobs of the machine, amounting to 50,000 units, I mean that that would be 50,000 volts. That is about the difference of potential which we are in the habit of employing when we are using these electrical machines. If I rub a piece of sealing-wax with flannel I get a difference of potential amounting to an enormous quantity like that, and yet I can get no serious injury from it, because the quantity of electricity is so small. We shall be going on to-day to show the means which we have for generating electricity in much larger quantities than we can by means of the appliances which were at our disposal in the last lecture. When we come to speak of batteries and the other means for generating electricity in quantity we shall be using very much smaller differences of potential than what we used in the course of the last lecture. A single battery may have one or two volts difference of potential, but the difference of potential that exists in the battery is exactly of the same nature as that which exists in the Wimshurst machine which you saw on the last occasion. The electric current which passes to the earth during a lightning flash is identically the same in character as the electric current which passes through our telegraph instruments, or which is lighting up this room at the present moment by means of these glow lamps round about. It is hardly necessary at present to insist upon it that there is only one kind of electric current. In former days it required the researches of the ablest experimenters to prove to the scientific world that the electric current generated by means of our Wimshurst machine was the same in

Digitized by Google

character as the electric current which can be generated by means plates of metal in an acid. But we know with certainty that the effects are the same. I shall simply attempt to show you one experiment with the Wimshurst machine to prove to you that one of the effects which we shall frequently find in dealing with batteries can also be produced by means of such an influence machine. I have here a small piece of tin foil, which I shall place between two pieces of glass, and I shall then subject the two ends of the tin foil to the influence of an electromotive force due to the difference of potential between these two poles—these two knobs. Then when I discharge this machine, which enables us to get a considerable quantity by means of the Leyden jars attached to it, we shall be able to pass the current through this piece of tin foil and show the heating effect which is thereby produced. This is a neat illustration of the analagous effects which may be produced by means of this influence machine and the totally different means of generating electricity which we have in batteries or dynamo machines. [Experiment.] The spark has now passed between the poles, and I will just hand round one of the tin foils that were put there originally and another showing the fused condition of the tin foil immediately afterwards. The effect is even more powerfully shown in this case, which I shall leave on the table, where not only has the tin foil been actually fused, but the glass has been pierced and shattered by the power of the discharge. [The various objects were handed round for inspection.] The quantity of electricity which is developed in the course of these powerful discharges is very small indeed. In fact, Faraday stated that in the most powerful lightning flash there is not so much electricity passing as there is at the time when we decompose by an electric current a single drop of water—the quantity is so very feeble. But there are many ways in which we can conceive of an electric current passing when bodies are charged in this way. For instance, if a conductor were to be moved backwards and forwards between these two poles there would be a steady conveyance of positive from one side to the other, and of negative electricity in the opposite direction, which is identical in character with an electric current. Many years ago Prof. Rolland, working in Berlin, saw that an electric current could be produced in another way. Simply by charging a body with electricity and moving it with great rapidity, he was able to produce effects analogous to those which are to be seen by the use of a current generated from a battery—such effects as we shall presently be observing. Then Prof. Rolland accordingly proved by experiment that the carrying of a charged body through space is equivalent in its action to an electric current such as we shall be dealing with to-day. I will now show you some simpler methods we have for creating an electric current, and I will begin by throwing upon the screen a cell containing dilute sulphuric acid. Having thrown upon the screen this cell, I will in the first place introduce into the cell a wire of copper; and you see that the wire there is in perfect focus, with nothing else near it. I will now introduce a piece of pure zinc, and there is not the formation of gas or anything appearing there. I will now introduce the two simultaneously—the zinc and the copper—and still there is no appearance of any gas whatever in that arrangement; but so soon as I touch the two metals we shall see that there is an evolution of gas. Gas now is seen to be given off from the thin one, which is the copper. That gas is hydrogen gas, and it shows that the condition of the cell is something different from what it was before. As a matter of fact there is an electric current passing through these metals. Instead of connecting them in the liquid it is sufficient to connect them outside the liquid, and now the gas is still seen to be given off from the copper. The hydrogen is seen rising in small bubbles. [Experiment.] I will now, instead of connecting them as I have done at present, which is an outside connection, connect them metallically by a good conductor, and make the metal connection by a long wire which passes to this apparatus here and round the coil which you see facing you in the instrument there. [Indicated]. Inside this coil I have a magnet, to which the vertical index is attached. We shall see that when the current which we have spoken of is circulating through the wire in this coil there is a deflection of the magnet, and that these will serve as an indicator to us in the rest of our experiments to show when we have got a current or not. I now replace the zinc in the solution, and you see the bubbles being given off, and also the index marking that there is a current passing. [Shown.] I now remove this, and you will see that the index, after a few vibrations, will return to rest. [Shown.] Now, in making a coil for this purpose it is necessary, in order that the current may pass through all the different convolutions of the coil, to separate them from each other by an insulating material. If this were not done the current would take a short cut, and would not act in the manner we desire. To guard against this, my coil here is covered with silk thread, silk being an insulator, but that silk is not so thick as to prevent the difference of potential from passing across from one wire to the other if that difference were very great. If I were using a high difference of potential it would be necessary to use some thicker insulation than that. That is a point which has to be attended to in constructing powerful dynamo machines, and so on. We shall be using this apparatus as a galvanometer for measuring the current on several occasions. But we have another apparatus which is very often used by investigators, and which the philosopher finds peculiarly suitable for some very delicate measurements. That instrument is the ordinary Bell telephone, which consists of a magnet having a coil of wire wound round its end. The pole of the magnet is placed close to a disc of thin iron. Now, when a current which varies either in strength or in direction is passed through the coil, the attraction between the magnet and the disc is subject to similar variation. The consequence is that the disc gives off vibrations to the air, and an audible sound is heard, and as this instrument has become of great use—one which Prof. Hughes has largely used in his celebrated researches—I think it worth while to direct your attention to it. I will connect it with the battery, and take one end of the wire along the terminal of the battery so as to make and break contact very rapidly, and the telephone will give out a noise which will probably be audible to every person in the room. [Experiment.] That noise is coming from the telephone. The telephone is able to make the current audible through the whole room. You may imagine what a very feeble current may be audible when the experimenter himself places the telephone close to his ear. This, then, proves to us some of the effects which are produced by an electric current. An electric current is simply the result of our having an arrangement which enables us to keep up a constant electromotive force. In the case of influence machines, which I have been using so frequently, I am not able to maintain that high difference of potential constantly. If the two knobs are connected with a conductor, so soon as the contact is made with the conductor the whole of that quantity of electricity spreads through the conductor, and neutralises the whole effect. It is only by having a copious quantity generated or maintained by the chemical action that is going on in this cell that we are able to get a constant flow of electricity through the wire. The difference of potential created in this cell is exactly of the same nature as the difference of potential which we have between the poles of that machine. Now, I should like to bring to your minds a little more clearly the bearing of these experiments upon the production of energy in the cell, and which I have spoken of as the electromotive force of the cell. I have been using in this little cell a piece of copper and zinc in dilute sulphuric acid, and the electromotive force of that arrangement is perfectly definite. It does not depend in any manner upon the size of the apparatus. I have here a large cell containing large sheets of copper and zinc, and the electromotive force which is created in this cell is not one particle greater than that created in the other cell, and I can show this to you in a very convincing manner. I will connect this little cell with that very large cell in two different ways. I may connect the zinc of the one with the copper of the other, in which case I get a double effect. I get the sum of these two electromotive forces working throughout the metallic circuit. Or I may connect the zinc of this cell by a wire with the zinc of the larger cell, so that the two electromotive forces are acting in contrary directions. We shall then be able to see whether the electromotive force of the one is equal to the other, because the galvanometer will indicate to us the effect produced, which is due to difference in electromotive force, whatever it may be, between the two cells in which we are experimenting. Now, I have all the connections perfectly correct, so that the zinc of the little cell which I have been using hitherto is connected directly with the zinc of this large cell. The copper has a wire passing through the galvanometer and back to this large cell. Now, will you kindly watch the galvanometer while I introduce the zinc into this small cell, and so complete the circuit, and the deflection will be a very small one indeed. [Shown.] The needle is standing actually at zero. Now, I have two batteries in the circuit of zinc and copper, each of them capable of giving the deflection you saw, but they are so connected that they tend to deflect the needle in opposite directions. And as the needle remains at rest this shows that they are exactly equal in their effect. It will be well now to say a little about some of the different kinds of battery which are used. This arrangement does very well for a short time, but the trouble is with the gas which you saw upon the screen being deposited upon the copper. That hydrogen gas has an injurious effect, and tries always to set up a current in the opposite direction to that which we wish to utilise. Various means have been proposed to get rid of this hydrogen, and the first arrangement which was completely satisfactory was what was known as the constant cell of Daniell. Here I have a double cell of Daniell's construction, and here I have a slightly different cell—which you can examine afterwards—of Daniell's construction, which is not charged. Daniell's cell consists of plates of copper and zinc. I have two cells here, and the zinc of the one is attached to the copper of the other. The copper does not dip into the same vessel as the zinc, but is put into an interior vessel of porous material, through which the liquid can soak, and this vessel is filled with crystals of sulphate of copper—such as I have in my hand [shown]—dissolved in water, and the outer vessel in which the zinc is contains the sulphuric acid. In this case hydrogen is generated exactly as it was generated in the experiment upon the screen, but with this difference, that the hydrogen never reaches the copper, because the solution of sulphate of copper has this action, that it gives off the copper from its molecules, and takes in the hydrogen instead, and thus the solution is decomposed, part of it being converted into sulphuric acid by uniting with the hydrogen, and thus bubbles of hydrogen are never allowed to accumulate on the copper plate. In the centre of the table there is a large battery of Daniell's cells, which can be examined afterwards, and where you will see the arrangement of them when they are put in series, so as to increase the electromotive force. In that battery there are five of these cells, and therefore we have five times the electromotive force, and five times the power of overcoming resistance. Further along we have five Leclanché's cells, such as are used in the Post Office. Here I have a battery of totally different construction. This is not dependent upon chemical action, but is dependent on the conversion of heat directly into electricity. This pile which you see before you consists of a series of pairs of two different metals; one is iron, and the other is a compound of zinc and antimony. Each pair is joined together at the outside of this pile, and they are then joined so as to make a continuous series joined at their centres, so that the different pairs are joined in series right round the pile, and from the top to the bottom, making in all something like 75 pairs coupled altogether in series so as to multiply the electromotive force of a single pair by 75. This is connected with the galvanometer, and you see that when I make contact there is no current passing whatever, the reason being that the temperature of the inside and outside

Digitized by Google

junctions of this apparatus is the same. But now I will take a light and heat up the interior by means of a burner which is now acting, and you will gradually see the formation of the current—it takes some five or ten minutes to acquire its maximum effect. [Experiment.] Now you see the effect of current which is being sent through the galvanometer. In a battery we have two things to consider, not only the electromotive force which is capable of generating the electricity, but also the resistance of the battery. When we have our complete circuit, consisting of any one of these batteries, to generate the electricity, wires going to the apparatus to carry the electricity, and an apparatus in which the electricity is to be used, we have two things to consider. We have a certain amount of electromotive force in this circuit, and we have a certain amount of resistance in this circuit, the greater the electromotive force the greater will be the current we get, and the lower the resistance in the circuit the greater will be the current which we get. Consequently, in order to get the best effect we generally wish to have a battery of very low resistance and very high electromotive force, but we also wish to have a small resistance in our wires which go to the apparatus on which we are using the electricity, and we also want a small apparatus where the electricity is being used. At the present moment I have got a zinc plate fully immersed, and a copper plate only just dipping into the liquid and the needle, and you see that we have a deflection of about 45 degrees or thereabouts. I can vary the conditions of the problem by varying the resistance of the battery. Leaving the resistance of this galvanometer the same—leaving the wires identical—I can lower the copper plate into the liquid, and thus diminish the resistance of the battery, and as I do so the deflection immediately increases. [Experiment.] Now the needle is permanently deflected quite to the end of the scale, and it resists intensely any effort to cause it to rise, showing this—that the current is stronger when the resistance of the battery is diminished. In the same way it may be shown that, if I brought the plates nearer together, the resistance would be less, and consequently we get a greater deflection; for, having a larger surface of plate, or having the plates nearer together, tends to diminish the resistance. Now, what happens during the time that the current is passing? I am not going to ask you to go into the theoretical views of any persons on electricity in this connection. We know that there is a certain stress in a medium when electrified bodies are fixed in equilibrium, and we know that there is a change in this condition of stress when the equilibrium is destroyed. But I am not going into what kind of change that is, and what is the medium under these circumstances. I wish to ask what becomes of this energy which is being created when it has overcome a resistance in the outer circuit? The answer to that in the first place is that the energy cannot be destroyed, and in accordance with the principle of the conservation of energy we must be able to find out what it is converted into, and we find by experiment that the energy when passing through a resistance is converted into heat. This is a transformation of one kind of energy into the other, which transformations lead to notions of the correlation of physical forces, and the conservation of energy, of which there are so many illustrations in physical science. It will take but a few moments to show the transformation of one kind of energy, heat, into the other kind of energy, electricity. Now we are speaking of the changing of electrical energy into the energy of heat. I will show you many illustrations of this principle. I could not show you a better one than the means of illumination which we have in this room now. In every one of these glow lamps we have a brilliant illustration of the conversion of electrical energy into heat. The heat in each of these glow lamps is very large, and the whole electrical energy consumed in these lamps is shown to us by the brilliant light and consequent radiation of heat which takes place from these lamps. I will make use of these very glow lamps to illustrate some of the other points in connection with resistance. I will connect one of these lamps with a battery containing a certain number of cells. Fifty-five cells are upstairs, and are connected by a wire with the wire I hold in my hand. I now make the contact here, and immediately the glow lamp, which is connected and in the circuit, gives off a certain amount of heat, and that brilliant glow is an indication to you of the strength of the current [shown] when the resistance of a single glow lamp is in the circuit. I now change the connection, and put two of these lamps in series, so that I have nearly doubled the resistance of the circuit, and you will see that the current is by no means so strong, as is shown by the fact that the lamp only acquires a dull red heat. [Experiment]. I might show you numerous illustrations in confirmation of the fact that when we increase the resistance we diminish the current, and when we diminish the resistance we increase the current. Here I have a platinum wire stretched, through which I shall pass an electric current so as to render it incandescent. Part of this platinum wire is straight, and a small portion of it is coiled up into a loop. I will place a spirit lamp under the coil part. By heating this coil part by the spirit lamp I increase the resistance of that portion because the resistance of the wire increases with the temperature, and what I want you to see is that when I increase the resistance of that platinum wire by bringing the spirit lamp under it the current is diminished, and therefore also the intensity of the glow in the other part of the wire. [Experiment.] Consequently, I shall begin by showing you the converse of the experiment. I will cool that glowing coil, and thereby diminish the resistance, and the increase of current which ought then to flow through the wire will probably be susceptible to you by an increased glow in the straight portion of the platinum wire. [Experiment.] I wish you not to concentrate your attention upon this bright glow, but upon the straight portion of the wire, which is glowing comparatively feebly. I will put the ice on to this part of the coil, and see whether we are able to get an increase in the straight portion of the wire. [Shown.] Distinctly, there is an increase. I will now try to get the effect of heating it still more by aid of the spirit lamp. [Experiment.] There is a decided diminution in the brilliancy of the straight portion of the wire, showing that the current has been diminished by the heat of that wire. I have shown you now how a current may be increased or diminished by the resistance which is in the battery, or which is in the conducting wire. I should like to show you a similar effect with the galvanometer. This leads me to say a few words about the choice of the galvanometer for delicate experiments. The greater number of turns I have round my galvanometer, the greater number of times is the needle influenced by the galvanometer. Each turn exerts its influence. Therefore, you may expect the greater the number of turns you have round the galvanometer, the greater will be the influence upon the needle. But, on the other hand, when we increase the number of turns round the galvanometer we increase the resistance, and when we increase the resistance too much, we may diminish the effect in the galvanometer. It is often remarked that for certain kinds of work, such as Atlantic telegraphy, we require high-resistance galvanometers. The student is sometimes perplexed and led to think that the virtue of a high resistance galvanometer is in its resistance. It would be, perhaps, less misleading to call it a "many-coil" galvanometer. I have here a compass needle which I am able to project on the screen with a hydrogen lamp, and I will show you the effect of a coil through which a current is passing. You see the compass needle, which I will first bring over the zero line. I have a coil in its neighbourhood capable of deflecting the needle. I will connect the coil, and you will observe the deflection. [Experiment.] Observe exactly what is the position of the needle. It is at the fourth division from the zero line. At the present moment I have got 10,000 turns round the coil of my galvanometer. I will reduce the number by 2,000, and you see the deflection increases when I reduce the number. In reducing the number of turns I have also increased the resistance, and the result was that it went further away from the zero line. I will now take out another 2,000 turns, and you will see the needle go a little further in the same direction, showing an increased effect, and finally I will take out another 1,000, and there will be a slight impulse, I think, in the same direction, thus showing that we get an actual increase in the deflection when we diminish the number of turns in our galvanometer. Another very beautiful illustration of the consumption of energy by producing resistance is in the electric arc. The electric lamp, which you have seen at work in the different illustrations, is produced by two pieces of carbon connected with the poles of a powerful battery, and brought first to touch and then separated to a slight distance. This experiment was first performed by Sir Humphrey Davy. [Experiment.] Now, these are the images of the two carbons whose ends are placed opposite each other, and a great deal can be learned by a careful study of that magnificent image. In the first place I will show you that they are not touching, and yet the current is able to pass across. The only reason why it is able to pass across that sensible space of air is that the air becomes enormously heated, and when the temperature of the air is increased, as it is in this case, it becomes a fair conductor of electricity. There the carbons may be seen glowing hot. [Experiment.] They touch, you notice, and then an automatic arrangement separates them. You will notice particles of carbon continually flying off, small portions of electrified matter being continually given off. This pole, which is called the negative pole, is connected with the zinc of the battery. This, which is called the positive pole, is connected with the copper of the battery. You will notice an accumulation of impurities on the surface of the globules. I should like to be able to show you the deflection of this current, which you can see by the illumination which exists between the two poles. If Mr. Devonport would introduce a magnet there you would see the violent evolution of these particles of carbon. [Experiment.] I wish now to try and show you an experiment of another kind—not the heat that is produced by electricity but the chemical action which the heat produces. Here I have a current going to two platinum points at the bottom of this dish of water. Now I will send the current through it, and I shall be able to show you the evolution of gas. [Shown.] This is one of the most elementary of the chemical phenomena which are produced by electricity. If I were to allow that to go on we should get the tubes filled with oxygen. [He concluded this experiment at the close of the lecture.] In the meanwhile I wish to try and show you the way in which electricians actually measure the resistance of any wire or any other material which may be before them; and it is founded upon the principle that if we connect the wires with a galvanometer at two points which are of the same electrical potential, no current will pass through the galvanometer. Professor Adams has made some very pretty experiments in his laboratory in tracing out the potential lines in that way. This is one of his actual experiments. [Indicating it.] But perhaps this rough sketch in chalk brings out more forcibly the same results. He was able to trace out along these potential lines a line in which the potential was equal all over, and so succeeded in determining the difference of potential in the rest. Now, I am going to apply the same sort of thing in measuring resistance. Here is a piece of gilt paper. It is an irregular piece of paper. [Exhibiting a strip of gilt paper of varying breadth, he demonstrated by means of the galvanometer how to find the difference of potential.] Now, I wish to show you a very peculiar experiment. Here I have a highly polished steel plate. It has no mark upon it whatever. I will put it into this vessel, which I will fill with acetate of lead, and then I shall place a sheet of copper just dipping into the liquid, and finally I shall pass a current through from the bottom steel plate to the other copper plate, and the consequence will be that there will be a deposit of peroxide of lead, varying in thickness, thereby showing the beautiful colours of thin films which Sir Isaac Newton worked at, and which are caused by the varying absorption of light due to the varying thickness of the films of peroxide. [Experiments.]

COMPANIES' MEETINGS & REPORTS.

Railway and Electric Appliances Company.

The ordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel on the 28th ult., under the presidency of Colonel R. R. Jackson.

The SECRETARY (Mr. W. Shepherd) read the notice convening the meeting.

The CHAIRMAN, in moving the adoption of the report and accounts, regretted that there had been no marked improvement in the position of the Company since their meeting last year. The loss at the Polmadie Works, together with the expenses in London, had been £3,753. Of course, in their financial position this was a heavy loss, but still it was less than that of the previous year, which amounted to £4,888. In that year, however, the loss was increased by £700 on account of depreciation, whereas for 1885 nothing had been allowed for depreciation. The loss at the works in 1884 was £1,885, against £845 last year. Although, however, the loss on the working of 1885 appeared as £3,753, that included £2,000 for directors' fees, but as the Board proposed to take only £450, the loss was practically reduced to £2,200. The Board intended to reserve control over the sum of £1,550, which they were not taking, in order, if necessary, to meet contingencies like those which arose in 1884, when the Directors really had no remuneration. There was no doubt that their working in the past year had been affected by the depression of trade—a circumstance not peculiar to their Company; and beyond that they had had to face a disappointment. He informed them at the last meeting that the Williams cross-over had been successfully applied on one railway, and that they had received a second order from the company referred to. This second installation had given satisfaction to the railway company, and they had been led to suppose that it was probable that orders would be given to them by other railway companies. In that expectation, however, they had been disappointed, and they had not received a single additional order for anything made under the patents of Mr. J. S. Williams. He thought there could be no doubt that there was merit in those inventions, but he was not surprised at the conservative spirit exhibited by railway managers. Probably they would one day entertain a higher opinion of what he himself believed was an important invention. It was satisfactory to know that there was a continued demand for the waggon fastener, for which the Company held the patent. There was also an increased demand for the compensator, which they also controlled; and they had secured licenses for the use of some inventions on payment of royalty without in any way trenching on their funds. Another favourable feature was that they had received a large order for general business from an important railway company, and they had received smaller orders from other railway companies. He therefore thought there were indications that their business in that particular direction would develop somewhat freely. He could not say that he was able to put before them a sanguine picture, but nevertheless they ought not to give up the hope of seeing the Company in a better position.

Mr. F. G. SMITH seconded the motion.

The CHAIRMAN, in answer to questions, stated that they had been engaged in a number of lawsuits, which it had been their endeavour to get rid of. The result was that they had had to pay pretty heavily for law expenses, but nothing like the amount they would have had to pay had the lawsuits continued. If, as Mr. Cumming suggested, they were to sell the Polmadie works and do only an agency business, it would be just as well to take the next step, and wind up the Company. They thought they might get the Company into a better position by continuing the works. He then read a letter from a shareholder, suggesting the appointment of a committee to investigate the position of the Company before the proposed call of 2s. 6d. a share was made. He afterwards observed that it was better to pay a small call now, with the view to resuscitate the Company, than go into liquidation, which would involve the whole of the unpaid capital, 7s. 6d. a share, being called up.

The report was then adopted, and the retiring Directors and auditor were re-elected.

An extraordinary general meeting was next held, when the following clause was added to the Articles of Association:—"Article 38A. The Directors may accept from any member, on such terms and conditions as shall be agreed, a surrender of his shares or stock, or any part thereof."

The proceedings terminated with the usual complimentary vote to the Chairman and Directors.

Submarine Cables Trust.

Report of the Trustees to the fifteenth ordinary annual meeting of the certificate holders, to be held at the Offices of the Trust, 50, Old Broad-street, E.C., on 11th inst., at three o'clock:—

The revenue for the financial year, to 15th April last, including the balance brought from the previous accounts, viz., £1,949. 16s. 8d., and including the dividend on the Eastern Extension Shares referred to in the last report of £2,987. 11s., amounted to £23,776. 5s. 6d. The expenses of the Trust for the twelve months amounted to £1,349. 14s. 10d. The payment of two half-yearly coupons at the rate of 6 per cent. per annum absorbed the sum of £20,286, leaving a balance of £2,140. 10s. 8d. to be carried forward. The decrease of revenue this year has been entirely owing to the diminished dividend paid by the Anglo-American Company, in consequence of the competition with the Commercial Cable Company. The securities held by the Trustees remain unchanged. (Particulars of the original and present investments of the Trust are given as usual in the table which accompany the report.) The meeting will have to elect two auditors for the current year; Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

The Brazilian Submarine Telegraph Company (Limited).

Report of the Directors for the half-year ended 31st December, 1885, to be submitted to the twenty-fifth ordinary general meeting, to be held at the Cannon-street Hotel on the 12th inst., at 12 o'clock:—

The revenue for this period amounted to to £77,066. 0s. 10d., and the working expenses to £12,893. 5s. 5d. After providing £9,680 for debenture interest and sinking fund, and £1,199. 15s. 4d. for income tax, there remains a balance of £53,293. 0s. 1d.; to this is added £2,830. 16s. 3d., brought forward from 30th June last, making a total of £56,123. 16s. 4d. First and second interim dividends amounting to £39,000 have been paid, and £15,000 transferred to the reserve fund, leaving the sum of £2,123. 16s. 4d. to be carried to the next account. The message receipts for the half year amounted to £76,825, which shows a decrease of £12,178 when compared with the receipts for the corresponding period of 1884. This large decrease has been caused principally by the depressed state of trade and the decline in the rate of exchange. With respect to the latter the Directors are glad to report there is now a marked improvement in the exchange value of the milrei. All the Company's cables are in good working order. Acting under the authority given by the shareholders to the Board at the extraordinary general meeting held 21st January last, this Company has joined with the Eastern Telegraph Company and the Telegraph Construction and Maintenance Company in the formation of the African Direct Telegraph Company. That company's cable from St. Vincent to Bathurst on the African coast is already laid and will shortly be ready for traffic; the other cables are in a forward condition of manufacture, and it is expected that they will be laid and in operation during the present summer. The interest of the Brazilian Company in the telegraphic communication with the West Coast of Africa is very important. The line will be worked at St. Vincent in this Company's station, and it is agreed the telegrams between England and Africa for and from the African Direct Telegraph Company's system shall be conveyed by the cables of the Brazilian Company between St. Vincent and Lisbon, and by those of the Eastern Company between Lisbon and London.
